INDEX TO VOLUME XCIV

MINING AND SCIENTIFIC PRESS

From January to June, 1907.

A

		PAGE.
Abbott, James W	A Visit to Ely, Nevada	739
Ditto	Mining at Bingham, Utah	596
Ditto	The Greenwater District	52
Ditto	The Requirements of Modern Mining	815
Abyssinia, Minerals in		571
Acetylene Lamps	George E. Collins	626
Acid Flotation Processes at Broken Hill	F. H. Jaekson	728
Adaptation of the Stadia to Small Scale, Reconnaissance Surveys	R. H. Chapman	91
A. & E. Slime Concentrator, The		350
Affairs on the Rand	Editorial	578
Alaska, Geological Exploration in		97
Mail, Articles Allowed in Interior		97
Stream Flow in		574
Alderson, Matt. W.	A Miner's Drills and His Work with Them	284
Ditto	Those Bob-Tailed Words	431
Ditto	Letters of a Self-Made Miner to His New Foreman (I, II, III, IV)	602, 631, 669, 698
Atey, Frank	A Clever Bit of Engineering	189
Algeria, Mining in		725
Allen, Carl A.	Notes on Mexican Mine Labor	345
Allis-Chalmers Ball-Mill		317
Alluvial Mining in California	Editorial	194
Aluminum		281
Amalgamation of Copper Ore	Wm. H. Baur	146
Pan	H. W. Bangle	826
Amalie District of California, The	L. H. Dyke	764
American Copper		88
Spiral Pipe Works, The		191
Anaconda Smelter, Enlarging the		183
Ancient River Channels of California, The	George W. Kimble	726
Anderson, Robert	The Geology of Japan	732
An Idea	W. S. Haskins	626
Annealing Steel		122
Antimony, Price of		253
The Volumetric Estimation of	James Darroch	94
Arizona, Secondary Changes at Cherry Creek	John A. Reid	31
The Vulture Mine	C. W. Purington	308
Arnold, C. Everard	The Sherman Concentrating Table	600
Assay of Cyanide Solutions	H. W. Gendar	401
Ditto	Augustus MacDonald	719
Ditto	Douglas Muir	564
Ditto	W. F. Tindall	720
Assay-Furnace, A Compound	W. J. Fleck	567
A Simple		151
Assaying, Reducing Agents in		242
Aubury, Lewis E.	The Mineral Industry of California During 1906	26
Austin, L. S.	The Deister Concentrator at the Baltic Mill	35
Ditto	Overfire in Copper-Matting Blast-Furnace Practice	33
Ditto	The Settling and Collection of Dust in Flues	668
Ditto	A Slag-Casting Machine	282
Ditto	Tredinnick's Process for Desilverizing Lead	89
Ditto	Weight of Charge as Affecting Reduction in Silver-Lead Smelting	61
T. S.	Silver-Lead Smelting Practice (I, II, III, IV)	252, 311, 537, 762
Australia, Encouraging Prospectors in	Editorial	67
Mining Labor in	W. J. Loring	509

B

Bailey, Wm. R.	Salton Sea	400
Baltic Mill, The Deister Concentrator at the	L. S. Austin	35
Bancroft, Geo. J.	Salton Sea	595
Bangle, H. W.	Pan Amalgamation	826
Banks, E. G.	Cyanide Practice at the Waihi	593
Barry, H. P.	Tube-Mill Lining	399
Battery Foundations of the Kuk-San-Dong Mill, Korea	Charles D. Kaeding	598
Baur, Wm. H.	Amalgamation of Copper Ore	146
Beaches of Nome, The	Otto Halla	688
Beason, L. H.	The Garfield Mill of the Utah Copper Company	471
Bell, John M.	Obituary	612
Robert N.	The Gold of the Snake River	542
Big Shafts of Guanajuato, The	T. A. Rickard	185
Bingham, Utah, Mining at	James W. Abbott	596
Black Sand	Editorial	68
Ditto	L. A. Maxwell	533
Ditto	John M. Nicol	82
Black Sands Again	Editorial	320
Black Sands	C. P. Ferry	753
Ditto	Charles Janin	431
Blake, J. R.	Slime Filters	564
Blast-Furnace v. Reverberatory	Harry L. Charles	114
Ditto	James W. Neill	815
Boarding House, The Mine	F. N. Fletcher	783
Bob-Tailed Words, Those	Matt. W. Alderson	431
Bodie District, California, The Geology of the	R. P. McLaughlin	795
Boise, The Trial at	Editorial	736
Bonanza Ore, The Sampling and Assaying of a Car of	Lochiel M. King	241
Bosqui, F. L.	The Moore and Butters Filters	148
Boundary District, British Columbia, The	Forbes Rickard	511
Bradley, Walter W.	Tube-Mill Lining	17
British Columbia, The Boundary District	Forbes Rickard	511
The Mineral Output of, in 1906		50
Broken Hill, Acid Flotation Processes at	F. H. Jackson	728
Proprietary Mine, Ore Treatment at	G. D. Delprat	407
Brown, Walter S.	A Filing System for Mining Engineers	464
Bucke, Horace W.	The Meaning of Striations	432
Bullock, L. McN. B.	Butters Copala Mill in Sinaloa, Mexico	221
Ditto	Cyanidation at Copala, Mexico	335
Ditto	Cyanide Practice at Copala	719
Burlesque of Mining, The	Editorial	226
Burrows, R. H.	The Lluvia de Oro District, Mexico	664
Butters Copala Mill in Sinaloa, Mexico	L. N. Bullock	221
Butters Filter, The	James Frier	432
Ditto	Mark R. Lamb	152
Ditto	Mark R. Lamb	400
Ditto	E. S. Pettis	367
Mr. Lamb and	Edward H. Nutter	210
Butters Method, The Filtration of Slime by the	E. M. Hamilton	785, 813

C

California, Alluvial Mining in	Editorial	194
The Amalie District of	L. H. Dyke	764
The Ancient River Channels of	George W. Kimble	726
Copper in Shasta County	William Forstner	625
Copper of Shasta County (I, II)	Donald F. Campbell	28, 55
The Mineral Industry of, During 1906	Lewis E. Aubury	26
Miners Association		144
Miners Association, The	Charles G. Yale	53
Quicksilver in	Charles G. Yale	22
Calumet & Hecla	Editorial	288
Campbell, Donald F. Copper of Shasta County, California (I, II)		28, 55
Canadian Mining Institute, The		321
Canda Tempered Steel Jaw-Plate		66
Carniola, Austria		122
Car Shortage in the Middle West		59
Celebrated Case, A	Henry M. Hoyt 2nd	695
Ditto	Grant H. Smith	751
Channing, J. Parke	Price of Copper	148
Chapman, Robert H.	An Adaptation of the Stadia to Small Scale, Reconnaissance Surveys	91
Ditto	Death Valley	215
Charles, Harry L.	Blast-Furnace v. Reverberatory	114
Ditto	Converter Lining	572
Cherry Creek, Arizona, Secondary Changes at	John A. Reid	31
Chicago Giant Rock-Drill		286
Chile, Mining in	Editorial	799
Chlorine, Production of, from Salt		90
Clark, J. C.	How to Wild-Cat	689
Clarke, Robert	Pans v. Tube Mills	431
Clever Bit of Engineering, A	Frank Atey	189
Cobalt, Ontario	T. A. Rickard	23
Ores, The Smelting of	Hiram W. Hixon	406
Coeur d'Alene, Progress in the		243
The Troubles in the		754
Collins, George E.	Acetylene Lamps	626
Colombia, Railway Construction in		720

PAGE.

Colorado, Geological Survey for....Editorial.... 320
Combination Prospecting Drill, A.... 608
Comedy in Three Parts, A....E. A. H. Tays.... 273
Comparison of Coal and Oil Muffle Furnaces, A....George J. Young.... 700
Compound Assay-Furnace, A....W. J. Fleck.... 567
Concentrates ...15, 51, 81, 113, 145, 176, 209, 240, 272, 302, 334, 366, 398, 430, 460, 506, 530, 562, 592, 621, 656, 687, 718, 750, 782, 814
Concerning Costs....George Huston.... 630
Confidential Information Safeguarded.... 660
Conrey Dredge, The.... 159
Converter Lining....H. L. Charles.... 572
Copala, Mexico, Cyanidation at....L. McN. B. Bullock.... 335
Cyanide Practice at....L. McN. B. Bullock.... 719
Copper, American.... 88
A Curious Occurrence of....C. Y. Knight.... 242
In Del Norte County....John B. Platts.... 303
Exports and Imports.... 347
In Serpentine....C. W. Purington.... 719
In Shasta County, California....William Forstner.... 625
Of Shasta County, California (I, II)....Donald F. Campbell....28, 55
Matting, Overfire in, Blast-Furnace Smelting Practice....L. S. Austin.... 33
Ore, Amalgamation of....Wm. H. Baur.... 146
Ores, Some New Points in the Geology of....James F. Kemp.... 402
Price of....J. P. Channing.... 148
Prices....Editorial.... 548
Range Consolidated, Amalgamation of....Editorial.... 131
Range, Notes on the.... 375
The Production of.... 241
Corbett, J. Leslie....Letter from.... 116
Cornish Tin Mining (I, II)....H. E. West....179, 213
Correction, A....Chas. D. Walcott.... 367
Cost of Dredging.... 278
of Labor on the Rand, The....Edgar P. Rathbone.... 46
Crane, W. R....Steel Ore-Bin Construction.... 304
Cripple Creek, Mining in Depth at....Victor C. Hills.... 376
Crowther, Joseph....Obituary.... 770
Curb, Trading on the.... 278
Curious Occurrence, A....H. E. West.... 16
Occurrence of Copper, A....C. Y. Knight.... 242
Cyanidation at Copala, Mexico....L. McN. B. Bullock.... 335
Progress in, During 1906....Alfred James.... 18
Cyanide Clean-Up....James E. Thomas.... 62
Mill, Treatment of Matte from the....A. E. Drucker.... 638
Poisoning....A. P. Kennedy.... 303
Practice at Copala....L. McN. B. Bullock.... 719
Practice at the Waihi....E. G. Banks.... 593
Solutions, Assay of....H. W. Gendar.... 401
Ditto....Augustus MacDonald.... 719
Ditto....Douglas Muir.... 564
Ditto....W. F. Tindall.... 720
Cyclone Drill, The.... 256

Editorial.

THE OFFICES of the American Institute of Mining Engineers were moved from 99 John St. to 29 West 39 St., New York, on January 1. This address indicates removal to the United Engineering Society building. We hope the affairs of the Institute may be blessed with unbroken prosperity and that the multiple activities of the veteran secretary may proceed with wonted vigor and effectiveness under the new roof.

ON THE LAST day of the year a conference was held at New York between the State Geologists and the Director of the United States Geological Survey, for the purpose of discussing the relations it is proper to maintain between the Federal bureau and those of the various States. This is the result of recent unpleasant incidents, and indicates a desire to clear a situation that promised to be complicated. We trust that the deliberations were to the benefit of economic geology, preserving the opportunity for individual research, as well as State work, while giving proper consideration to the more comprehensive investigations of the National scientific bureau.

IT APPEARS that the Federal authorities intended to use Wyoming sandstone and Indiana limestone in the erection of the new Government buildings at Los Angeles. The matter was brought to the attention of Mr. Lewis E. Aubury, the State Mineralogist, and he promptly telegraphed to Washington, protesting against this choice of building stone, there being equally good material available in California. In the quarries of Ventura, San Luis Obispo, Santa Clara, and Colusa, the contractors can obtain all that is needed. It is not obvious why the railroads should be presented with the cost of bringing stone from distant localities.

EVERY YEAR at Christmas the management and the men of the North Star mines at Grass Valley meet together in good-fellowship. The company presents each miner, from the youngest to the oldest, with a piece of gold, and the men give the manager and his assistants something to express the kindly feeling existing between them. Last week this function marked an event of greater importance, for Mr. A. D. Foote, the manager, announced that the company had voluntarily decided to adopt the eight-hour day; this included the abolition of the 'grave-yard shift'. In addressing the men, Mr. Foote expressed his confidence that just as much work would be accomplished as in the longer hours hitherto customary, and we have no doubt that this is true if the men accept the concession in good faith. Managers as a rule do not object to the eight-hour day when it yields eight hours of honest work, but in many cases it means much less, every effort being made to steal time so that

the employer does not receive what the implied contract calls for. But the best way to solve labor problems is by fair dealing on both sides, and for this reason we welcome the example of the North Star Mines Company.

AN EFFORT is being made by Messrs. C. C. Moore, H. T. Scott, and other energetic citizens of San Francisco to promote closer commercial relations between our City and the new goldfields of Nevada. This movement is worthy of support, especially as one of its objects is to secure better railroad facilities between this great seaport and the desert plateau, now the scene of widespread mining activity.

ACCORDING to *The News*, of Denver, there is a geological feature at Idaho Springs that gives that mining centre unusual "prestige," and that is "a great volcanic dike which is said to entend from New Mexico to Canada," running in some roundabout way from Goldfield, Nevada, to Cripple Creek, and then to Idaho Springs, where it blossoms in a truly magnificent manner. We do not know much about that "delirious trimmings" of a dike, but we can vouch for two streaks of metallic iron that extend down Clear Creek cañon with undeviating parallelism three feet asunder; at Denver these streaks enlarge, and traveling 4 feet 8½ inches apart they reach as far north as Cheyenne, connecting there with other streaks that go eastward to Omaha, and westward even to Goldfield, and many be the weary ones that tramp along the strike of those streaks.

ONE OF the interesting features of the past year has been the aggressive policy and growing business of the United States Smelting, Refining & Mining Company, which bought an important group of mines at Pachuca, Mexico, and secured control of the old Richmond and Eureka mines at Eureka, Nevada, besides conducting a mining and smelting business at Bingham, Utah, and in Shasta county, California, with refineries in New Jersey and Indiana. While appreciating the skill and integrity of the Guggenheim family, we regret to see their tendency to monopolize the smelting business and we welcome the growth of substantial competition. Such competition is undoubtedly beneficial to all concerned, and more especially to the owners of small mines, who in these days have good cause to be restive at the restricted market for their ore. Healthy rivalry between two large smelting corporations would be an admirable tonic for the mining industry.

THE AMALGAMATION of the Greene Copper Consolidated mine with the Cananea Central and the passing of control from Col. W. C. Greene to Mr. Thomas F. Cole and his associates is an event of special interest because Col. Greene has been so thoroughly identified with the great mine that bears his name. The change is bound to be beneficial, for while Col. Greene belongs to the type of frontiersmen that explore new regions, he is not the man either by temperament or education to direct the operations of a big copper enterprise. Greene Consolidated in the past has had an air of opera bouffe and its real mining and smelting operations have been rendered rather undignified by the market attacks and counter-attacks of a group of men among whom it is only necessary to mention Gates and Greene. Copper mining on a big scale has no place for such performances; it is an intricate business, requiring financial ability of a high order and great technical skill. The old days of picturesque promoters are bound to go and among them Col. Greene was, and happily remains, one of the most successful.

Mining Speculation in 1906.

The year just ended has seen a marked increase in speculation both on our exchanges and at London, which is the distinctive mining market of Europe. On the whole, a great deal of money must have been made, though much of it may be still on paper, for the rise in stocks has been based largely on better metal prices and upon actual discoveries of ore. In the United States the most spectacular dealings have been in the shares of mines situated at Butte, Montana, at Goldfield, Nevada, and in the Cobalt district of Ontario, but there has been a tremendous transfer of money and stocks in connection with the copper mines of Michigan, Arizona, and Utah, and the gold-mining ventures of southwestern Nevada.

At Boston, the shares in the older mines of the Lake Superior region, such as Calumet & Hecla and Wolverine, possessing assured ore reserves and careful management, have seen an advance that seems warranted; the newer companies, such as Copper Range Consolidated, Allouez, and Mohawk, have been able to fulfill expectations formed at their flotation, and the rumors of combinations to be formed among groups of adjoining mines has stimuluted dealings, especially at the close of the year. But Boston, to which transactions in Michigan copper stocks are mostly confined, has been optimistic only, not excited beyond reason, although there has been some liberal dealing in a few of the Butte stocks, such as United Copper, Butte Coalition, and North Butte. On the New York Exchange the increased dividends of Amalgamated and Anaconda have provoked the customary gambling on a large scale, but the chief centre of speculative purchases of mining stocks has been on the Curb—the peripatetic mart on Broad street. Here there have been extraordinary scenes of excitement, especially during the last three months of the year. Dealings have grown enormously and the number of stocks quoted has been increased until the list is fairly representative of the mining activity prevailing all over the North American continent. In the first half of the year the new enterprises at Butte, more particularly those corporations that were formed immediately after the Heinze-Amalgamated truce, in February, were favored by speculators; indeed, the cessation of the cat-and-dog fight between the Standard Oil copper consolidation and Mr. Heinze released a great deal of property tied by injunction and produced a most excellent effect in Montana; as it was almost contemporaneous with important discoveries of rich ore in the northern part of Butte and with the extraction of rich stuff from the bottom workings of the Anaconda mine, the general result was to give great animation to the stock market.

The extension of the Bisbee copper district and the discovery of rich orebodies in the group of mines within the 'bonanza circle,' prompted active speculation in the shares of the Calumet & Arizona, Superior & Pittsburgh, Butte & Arizona, Shattuck-Arizona, and Denn-Arizona companies, dealings being scattered over many markets, for Michigan, Montana, and Pittsburg capital was largely instrumental in financing some of these enterprises at their inception, as the names indicate. This tendency of mining men to go out of their home districts is a good feature of the year's progress. Butte money has been put into Idaho, for instance, in the Snowstorm mine and in the Mullan district. Salt Lake capital is financing several copper prospects in southern Nevada; money made from Colorado mines has won handsome returns at Tonopah and Goldfield. This means that the experience of capable mine operators is applied to the exploration of new regions and there can be no question that money from such a source is better spent than that of the clerks, policemen, and cooks that dabble on the margin of ten-cent stocks.

The development of the big copper mines at Bingham has been reflected by the quotations for several Utah stocks that are dealt in at New York and Boston, but there has been no great rise, the successful exploitations of the mines being offset by the litigation with the farmers over smelter fumes, culminating in the unfavorable decision of the local courts. Similar ore deposits at Ely have furnished the basis, together with Guggenheim control, for great doings in Nevada Copper Consolidated, a stock that rose within a year from 6 to 22¾, largely on the proof of immense bodies of ore and the completion of the railroad. Two other established copper enterprises, exploiting low-grade ores of an opposite character, namely, Tennessee Copper, in the State of that name, and Granby, in British Columbia, have figured on the share lists, but without any pyrotechnic displays, both being held by strong groups of financiers. The Californian copper mines—in Shasta county—have played no particular part in speculation, although Lawson said some things about Trinity, but to balance this state of affairs, the Fresno Copper Company, a Glasgow enterprise based upon an unhappy mine in Fresno county, California, came to a most inglorious smash, with a drop in the shares, at Glasgow, from two pounds to two shillings within a few days.

There has been a healthy market in Cripple Creek shares, but it has been confined mainly to the local exchanges, at Denver, Colorado Springs, and Cripple Creek. Drainage projects have stimulated purchases of stock and transfers of property, fires, and flooding of workings have enlivened the market. At Salt Lake there has been an increased business on the local bourse, but dealings in the big mines have been made on the Eastern exchanges, and the local speculative movements have been without unusual features. In fact, the new centre of the spirit to get rich quickly by means of the buying and selling of mining shares has been further west. The gambling in Nevada stocks has been the most notable feature of the year.

Discoveries of extremely rich ore in the young mines of Goldfield, successful developments in the slightly older properties at Tonopah, and the finding of rich outcrops in a score of camps scattered over the Nevada desert, created a speculative fever that even the tremendous destruction of property by the San Francisco disaster was unable to check, save for a few days. Shares of all kinds have risen to many times their former price, and in the case of the Mohawk, a stock that sold for $2 in August rose to $20 in November. The prominence given to episodes of this kind tended to make a market for a number of cheap shares, based upon untried prospects, capitalized for large sums, and recommended in flamboyant advertisements. Much of this was fraudulent, but so much of it was based on real discoveries of ore that, in face of the public haste to gamble, there was no effort to make nice distinctions. At the close of the year, the occurrence of copper on the edge of Death Valley, at Greenwater, was made the excuse for several preposterous promotions, a capital of one or even two million dollars being saddled upon mere outcrops of low-grade stuff. It will take a lot of sober work and honest mining to cure the effects of this speculative debauch and, while a famous development of the desert region has undoubtedly taken place, the present year will have to pay the debt incurred during 1906.

Contemporaneous with the Nevada boom there was a wild orgy of speculation on the curb at New York, chiefly in shares of mines at Cobalt, the new camp in Ontario. Nipissing, which had been put on the market in May at $4¼ rose to $34, for 1,200,000 shares, on fabulous finds of silver and on the statement that the Guggenheims had bought control. When the last mentioned transaction fell through, there was a collapse and shares fell to 12. When Nipissing began to boom last summer a score of other Cobalt mines appeared on the curb market and many of these were boosted most successfully. Up to the first of December, the capitalization of Cobalt companies had reached $200,000,000, while all the ore produced by the district from the discovery to that date barely represented $5,000,000. Even after the Nipissing fiasco, the business of incorporation went on merrily. In the last week of December seventeen companies with an aggregate capital of $17,150,000 were incorporated in this district mainly on a slender showing of ore in prospect holes.

In conclusion, if we omit the absurdities marking the extreme forms of the essentially human desire to make money without work, it can be said that the speculative spirit of 1906 has been largely of a productive nature. Below the frothy talk and reckless doings of the irresponsible promoter and his easy victims, there has been a broad foundation of exploration and development. An adventurous spirit is needed in mining, which is a great quest for gold or the other metals, for without it the industry would soon shrivel to insignificant dimensions. During the past year there has been a tremendous uncovering of ore and extension of mining territory, especially in America, and the fruits of it will be manifest in the statistics of the future. Humanity being liable to error, especially when excited, there has been much money misapplied, but, having regard to the booms of other days, when greater extravagances and follies were perpetrated, we conclude that 1906 has seen good use of speculation as applied to mining.

Special Correspondence.

Butte, Montana.

Annual Statistics.—A Notable Increase in Copper Production.—Application of Electricity at Mines and Smelters.—The Coal Production of Montana.—Butte & Bacorn.—The Homestake Meeting.—General Development Co.—Lead Ore Produced.—The Butte & London.—Other New Companies Doing Exploratory Work.

In December the Butte district produced 27,491,420 lb. copper, making a total for the calendar year of nearly 343,000,000 lb. The various companies contributed to the year's production as follows:

Name of company.	Pounds of copper.
Boston & Montana	93,461,344
Anaconda	95,997,440
Butte & Boston	15,783,000
Washoe	12,700,000
Parrot	9,659,000
Trenton	13,398,400
North Butte	37,500,000
Butte Coalition	22,113,000
United Copper	7,400,000
Original	17,000,000
East Butte	7,200,000
Pittsburgh & Montana	4,753,500
LaFrance	2,790,000
Goldsmith	2,053,125
East Butte Extension	360,000
Lessees	520,000
Total	342,688,809

In 1905 Montana produced 320,000,000 lb. copper, so that there has been an increase of 33,500,000 lb. Butte copper ores yield, as a by-product, 2½ to 3 cents worth of silver for each pound of copper, making a total silver value of about $10,000,000 on the year's output. Some gold is also recovered.

To the December output the different companies contributed as follows:

Name of company.	Tons of ore.	Pounds of copper.	Yield per ton lb.
Boston & Montana	99,200	7,440,000	75
Anaconda	102,300	7,467,900	73
Butte & Boston	17,670	1,236,900	70
Washoe	14,260	998,200	70
Parrot	8,525	511,500	60
Trenton	15,190	987,350	65
North Butte	34,100	3,410,000	100
Coalition	31,000	2,232,000	72
Original	21,700	1,302,000	60
East Butte	6,820	613,800	90
Pittsburgh & Montana	4,340	338,520	78
LaFrance	6,975	488,250	75
Miscellaneous	6,200	465,000	70
Totals	368,280	27,491,420	

The Boston & Montana Co. will equip the Leonard mine with the electric haulage system and later on a similar change will be made at their other mines. Three locomotives will be placed in the Leonard, one on the 800-ft. level, one on the 1,100, and the third on the 1,400. The haul on these levels is long, 17 horses now being employed to do the work. It is expected that with the electric locomotives twice as much ore can be hauled in half the time. The locomotives and new cars have been ordered and will be delivered in March.——The Butte & Superior Co. has started sinking the shaft on the Black Rock, which was recently re-timbered to a depth of 500 ft. The shaft will be taken to the 1,000-ft. point without a stop.

The Amalgamated Co. is preparing to substitute electricity for steam in many of its mines, and also in its smelter at Anaconda. The mines are now undergoing the equipment necessary for the change. Many of the mine-pumps and air-compressors, as well as the concentrator at the smelter, will be run by electricity. The Missouri River Power Co. which furnishes power to the Amalgamated mines, is enlarging its plant and distributing lines and will furnish the Amalgamated mines with 17,000 h.p. in a few months. The use of electricity will not only mean a great saving to the Amalgamated Co., but will do away with the constant danger of a forced shut-down through shortage of coal.

According to the report of the State coal mine inspector, Montana has 32,000,000 square miles of coal lands and during the year mined 2,000,000 tons of coal. There are but three counties in which coal has not been discovered. The greatest percentage of the output is consumed by the Amalgamated Copper Co., the Great Northern, Northern Pacific & Butte, Anaconda & Pacific railroads. The largest continuous area of coal is embraced in the Great Falls field, which includes the Belt coal mines of the Anaconda Co. In the eastern portion of the State there is a great field of lignite, underlying several counties, varying in thickness up to 20 ft. A number of neighborhood mines have been opened and from them the people take their fuel as they need it, without charge.

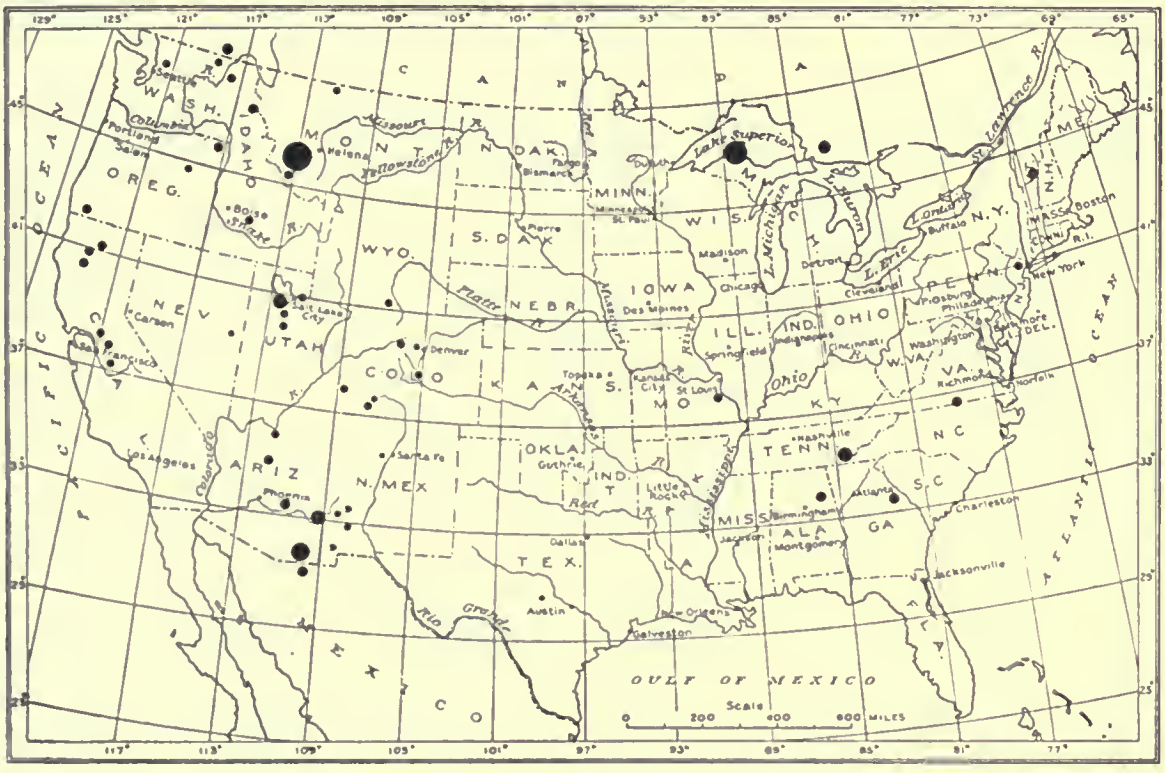
The Butte & Bacorn Mining Co. has cut another wide vein south of the 500-ft. station of the Calumet shaft. The vein is about 40 ft. wide and was cut 140 ft. south of the shaft. Although the ore contains silver and copper, it is not rich enough to be worked. The vein is practically dry, which convinces the manager and other mining men who have examined the strike that rich ore will be found when the water-level is reached. The company is now driving on a 17-ft. vein that was cut north of the Calumet shaft several weeks ago. In the north vein assays have shown 5 oz. silver and 1½% copper. Drifts are being advanced on the north vein and the ground is looking well. The manager, F. W. Bacorn, will soon resume sinking on the Calumet and take both that and the shaft on the Belinda claim down to the 1,000-ft. point before any more cross-cutting is done. The Belinda shaft is now down 615 ft. There are several more veins between the Calumet and Belinda shafts, that will be cut by a cross-cut between the two shafts. It was not expected that orebodies would be found above a depth of 700 to 800 feet.

The Homestake Mining Co., which owns some gold claims and several developed mines northwest of Butte in what is known as Brown's gulch, will have a meeting of stockholders on January 8, when a proposal will be submitted to make the stock assessable. The company is capitalized for $1,000,000, and has some good property, from which a lot of ore was mined a few years ago. For want of capital, however, to open the orebodies properly, no work has been done on the properties for several years. The company owns five claims in one group and five in another, and also owns a millsite and a small mill. Ore running as high as $551 per ton has been shipped from the property, and it has been the opinion of some of the stockholders that if a good manager could be placed in charge it could be made dividend-paying. The immediate purpose of making the stock assessable is to raise money with which to pay taxes and do some annual representation work on some of the unpatented claims. The property has been opened by three adits, one 380 ft., another 280, and the third 190 ft. long.

The stockholders of the Reins Copper Co. will hold a special meeting in Butte on January 31 for the purpose of voting on a proposal to increase the capital stock of the company from 1,000,000 shares to 2,000,000 shares. The call for the special meeting has been issued by Col. Guffey and his Pittsburg associates in the company. It is stated that the increase in the capital stock is for the purpose of buying additional property and providing more working capital. The Reins Co. recently purchased a fractional claim from the Ella Mining Co., paying therefor $240,000, which has been regarded locally as a very good price. It is stated the company has other ground under negotiation. For five or six years Col. Guffey and his associates

have been putting up money for expensive exploration work in the Combination mine. A small vein was recently opened and some ore is being mined from it.—— The General Development Co. of the Lewisohns is sinking three exploration shafts in different parts of the Butte district, one on the Granite Mountain claim, situated near the Jesse mine of the North Butte Co.; one on the Montgomery, south of the Bullwhacker claim, and the third on a piece of ground near the property of the East Butte Co., in the southeastern part of the district. The last mentioned and the Montgomery shaft will not be sunk more than a few hundred feet, but the shaft on the Granite Mountain is to be put down 1,000 ft. or more.—— The Colusa-Leonard Extension Co. has been financed by Eastern capital and is said to have sufficient backing to thoroughly develop its ground on the east side, where it owns 47 acres in a square block, just east of the Colusa and Leonard mines of the Boston & Montana Co. The shaft has already reached a depth of 100 ft., and is well timbered. It is expected that bedrock will be found at a depth of about 200 ft. The work is under the direction of Matt MacPherson, an experienced miner, and he is making exceptionally good progress in sinking the shaft.

The Goldsmith Co. is mining in the Little Georgia and Goldsmith mines and is making regular shipments of ore to the East Helena smelter. The ore runs high in gold and silver and about 4% copper. About 3,000 tons of ore per month are shipped from Butte mines to East Helena, mostly by lessees, who are working in the Alice, Moulton, Allie Brown, and other properties in the same neighborhood. The Allie Brown, which is owned by La France Co., is a lead producer, and one of the few lead mines in the Butte district.——The Butte & London Co. is engaged in cutting a station at 800 ft., and while that is being done sinking has been suspended, but it will be resumed next month. The station will be 50 ft. long, 12 ft. wide, and 10 ft. high, giving the room necessary for a pump of 1,000 gal. capacity. The rock is very hard and progress is slow. The shaft will be taken to 1,000 ft. and then a cross-cut will be started.——The Butte & Summit Valley Co., which is developing the Saratoga group of claims southeast of Butte, has encountered several stringers of copper ore in a cross-cut south from the 250-ft. station; this is taken to indicate that the vein is not far distant.——The Alliance Copper Co. has decided to sink its shaft another 100 ft., but before the work is started a heavier hoisting engine will be erected. The purpose of sinking is to tap the vein opened at the 200-ft. level and secure 100 ft. of stoping ground. The company owns 1,000 ft. on the vein.



Distribution of Copper Mines in the United States.

Cripple Creek, Colorado.

Annual Review.— Many Mines Worked Under Lease.— Successful Operations.— New Cyanide Mills.— Popularity of Cyanidation.— Transfers of Property.— The Drainage Adit.— Reduction in Rates of Treatment.

The principal feature of mining in this district during 1906 has been the large amount of systematic leasing of properties. Several of the mines are given over entirely to lessees, others partially, while only a few properties, such as the Portland and Strong on Battle mountain, and the Cresson on Bull hill, are worked entirely on company account. It has been rumored several times that the Portland Gold Mining Co. is about to lease its property, but the reports have been denied each time by the president of the company. One of the leases that has produced so well is that of F. R. Marsh and John Hodges on the Little Chara claim of the Work Co.'s property on Raven hill. Operations are conducted through the Moffat tunnel at a distance of over 2,000 ft. from the mouth. The lessees have made a profit of approximately $500,000. Soon after rich ore was struck by them, suit was brought by E. J. Knight, of Colorado Springs, for an $11/32$ interest in the profits; he lost his case in the District Court, and has now appealed to the United States Court at Denver.

The Western Investment Co. has operated several leases in the district during the year. On the Specimen and Sacramento claims of the Stratton Estate, situated on the southeast slope of Bull hill, a good-sized vein was encountered, which has produced a large tonnage of ore that gave returns of several ounces in gold. The same company also made good profits on La Bella lease of

the Golden Cycle mine, and also on Vindicator No. 11. The lease of Lew Hayden on the Gregory of the Elkton Consolidated Gold Mining Co. was also one of the best of the year. It expired in March last, but up to that time had made a profit of around a quarter of a million for the lessees.

The erection of cyanide mills for the treatment of the low-grade oxidized ores of the district has been an important feature. The Golden Cycle Mining Co. acquired the old Telluride mill from the General Metals Co. at Colorado City, which has been re-modeled to accommodate the cyanide process under the direction of Philip Argall of Denver. This mill, which will have a capacity of 250 tons per day, will soon be ready for work. Ore is already being sampled and stored for future treatment. The Isabella Gold Mining Co., on Bull hill, has erected a mill, which is now in operation for the treatment of their low-grade ores in the mine and on the dump. Other mills operating in the district are the Ironclad, situated on the hill of that name, being the smaller of the two Homestake plants; also the Anaconda, Home Run, Wild Horse, Pony Gulch, and Van Fleet mills. The Vindicator Consolidated Gold Mining Co. is erecting a small mill, at the present time, in the Lillie shaft-house, which belongs to that company. Low-grade ores running from $4 to $10 per ton will be handled, as well as sulphide ores, for the treatment of which an Edwards roaster has been installed. At the annual meeting of Stratton's Independence, Ltd., held at London on December 19, the erection of a mill on the company's property on Battle mountain was considered. Elaborate sampling of the mine and dump has been carried on this year to determine the quantity and value of the ore available for treating by cyaniding processes. The results were encouraging. Now that most of the mines have got to a stage where the greater part of the ore is low grade, ranging between $4 and $12 per ton, the cyanide process and its modifications seem to be the only means by which this ore may be treated at a profit.

During the year some important transfers of property have been made. The most important is the sale of the claims of the United Gold Mines Co., of the Woods Investment Co., to the Golden Cycle Mining Co. The purchase price was in the neighborhood of $350,000. The claims include the Wild Horse, Deadwood, Damon, Hardwood, Trachyte, Silver Tip, and the W. P. H. The Dillon property on Battle mountain, formerly under lease to Jesse Waters and John Price, has been bought by the Granite Gold Mining Co., whose property it adjoins on the west. The purchase price was stated at $160,000. The Granite Co. also acquired in the early part of the year the Gold Coin mine of the Woods Investment Co. The main output of the Granite mine had been hoisted for some time previously under contract through the Gold Coin shaft, which gave better facilities for the development and operating of that mine. The Trilby mine on Bull hill has recently been bought by Pittsburg and Philadelphia capitalists from the Moose Gold Mining Co. This property has produced some very rich ore at times, being leased intermittently up to the time of sale. Extensive development will now be done by the Eastern people.

The deep drainage project which has been brought before the public several times during the past year seems now a certainty. One million dollars has been subscribed by the mine owners of the district and as soon as the work is started, which will be during the month of January, subscriptions, it is hoped, will be obtained from the mills, smelters, and railroads. The place of commencing the adit is yet to be decided, but it will be either the Gatch Park or Window Rock sites.

The recent reduction in the open rates of freight and treatment charged by the smelter trust will benefit the camp to a great extent during the coming year. The difference of approximately $2 per ton will help materially in making a profitable market for the lower grade ores of the Cripple Creek district.

Johannesburg, Transvaal.

Too Much Politics.—The Chinese Question.—Passing of Dividends.—Loss of Confidence in the Rand.—Two Shafts Necessary.—Centralization of Management.

The dreary days of depression are being lit up by the fire-works sent off by the different political organizations. One is reminded of the stirring days of the 1896 campaign in the United States, over free silver. Gold versus silver is not the point at issue here. A purely industrial question, the question of Chinese labor, has been dragged into the arena of politics, and is being attacked and defended in a way never witnessed before in this country. The anti-Chinese brigade is still in the minority, but they are exceedingly bitter, and being opportunists they will join hands with Het Volk (the Dutch party), or any other party that will pledge itself to send the Chinese out of the country. There is going to be a terrific battle, during the next few months, over the Chinese question. Who will come out on top, it is exceedingly difficult to say. Personally I think the coolies will remain. Should the extremists get control of affairs, and insist on the immediate repatriation of the Chinese, then all I can say is, God help the Rand. Nearly half the mines will be forced to close down.

On account of the uncertainty of the future, a number of big corporations at their annual meetings have decided not to pay the usual dividends this year. It is possible that many of the mines will close down, if the Chinese are sent away, and as it is almost impossible to raise any money at the present time for future use, it is necessary to have large sums in the banks to meet the dark days that are possibly coming. There are strong rumors that several important deep-level propositions that are in the development stage will soon be forced to close down, on account of the shortness of cash. To issue reserved stock at the present time, for the purpose of procuring sufficient cash to continue operations, is almost impossible, as few people are buying South African shares.

There is no question that the financial side of the Rand is in a sad state. Anyone who will compare the prices of shares today with what they were two years ago will be appalled at the huge depreciation in value. There is little doubt that Europe as a whole has lost faith in the Transvaal. While there have been frauds, and grievous mistakes, this loss of confidence is not altogether justified. The output has reached a high figure, and the dividends paid by the better class mines are satisfactory. The loss of confidence is undoubtedly due to the feeling of uncertainty about the future. To send the Chinese away, close down half the mines, and heap more taxes onto the other mines, is certainly not the way to attract the investing public in England and the Continent. If things are bad with Chinese, what would they be without them!

The Government has appointed a commission to inquire into the subject of one shaft as against two, for deep level mines. At the present time the law requires a mine to have two shafts, or an opening into a neighboring mine, before a property can mine ore from stopes on a large scale. Several mines have been hard hit by this law. They have put down one shaft to develop a section of their mine, and as there are no openings near-by with which to connect, they have been forced either to cease mining, or sink another shaft. They have decided to

stop work. The report of the commission will be awaited with keen interest. Probably recommendations of exemption will be made, provided the mine with one shaft puts in forced ventilation, and uses steel head-gears, with the first few sets in the shaft of steel, to reduce the danger of a fire to a minimum.

The discussion over centralization of management has quieted down. It is rather extraordinary that the group where the centralization idea is carried to an extreme has the highest working costs on the Rand, in spite of very favorable conditions. On this group none of the individual mines have resident managers. One man is appointed to look after one department on each property. There is no supreme authority at any one mine. This explains the high working costs.

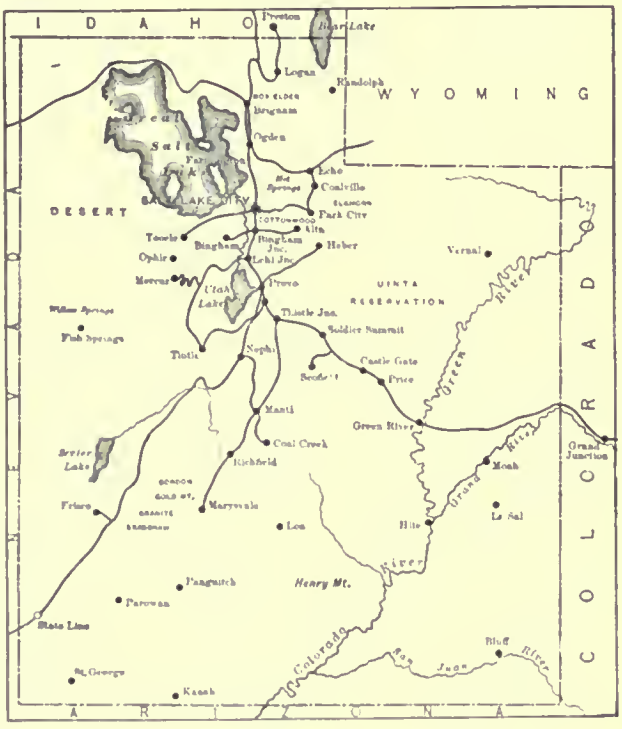
Salt Lake City, Utah.

Annual Review.—General Progress and Prosperity.—Smelter Fume Troubles.—Bingham Highly Productive.—Important Improvements.—Tintic Development.—Deep Mining.—Park City Hindered by Cave in Ontario Adit.—Record of Shipments.—The Alta District.—Mercur and Its Mines.—Stockton.—A New Gold Camp.—Other Promising Localities.—Record of Dividends.—Total Output of the State.

The year 1906 has been the most prosperous in Utah's history. Not only is this true as far as mining is concerned; but it also applies to every other kind of industry. The mining situation has improved particularly and I know of no better way to demonstrate this than to refer to the record giving the production of metals as well as to the table showing the dividends disbursed. There is no doubt expressed but that the present rate of progress will be as maintained in the new year, but it is just possible that the production of metals during 1907 will not come up to that of 1906 for the reason that an injunction issued from the Federal Court may compel several smelting companies to cease, or at least curtail, their operations as a result of the complaints made by the farmers in the southern part of Salt Lake county against smelter smoke. At least three of the smelting companies have decided to go elsewhere to conduct their operations, even if the Court should make some modification in its decree, which is declared to be about as drastic as could be, for it practically forbids the treatment of any ore mixture in a charge containing more than 10% sulphur. The smelting companies that are defendants in this case promptly made application for an appeal and, pending disposal by the higher tribunal, they are operating as usual under bonds of $100,000 each. It is expected that the case will be reached in June, when the smelters will have to close, should the decision of the lower court be affirmed. However, great hopes are entertained that some arrangement will be brought about whereby the existing plants will be allowed to continue until such time as new ones are completed and ready for operation, so as to work no serious hardship upon the owners of producing mines or those who are dependent upon them for support.

Bingham is the big mining camp of the State at the present time and is likely to bear that distinction for a good many years to come. While its mines are principally productive of copper, lead continues to be produced.

The ore sent to the smelters during the past twelve months has averaged between 4,000 and 5,000 tons, and employment has been given to about 4,000 men, meaning a monthly expenditure in wages approximating $425,000. An immense amount of capital has been invested in the Bingham district and in most instances mining is conducted there upon a large scale. The most striking example of this is found in the work of the Utah Copper and Boston Consolidated companies, which now have under construction at Garfield, 15 miles west of Salt Lake City, two concentrating mills. Both will be completed during 1907; the former is being built to treat 6,000 and the latter 3,000 tons of the low-grade monzonite copper ores characteristic of Bingham. Both the companies mentioned have introduced steam-shovel practice and for several months past stripping of the overburden has been in progress. The Boston Con. has two shovels of the type used in digging the Panama canal and two others will be placed in commission during the next few weeks. The Utah Copper has been working with a smaller shovel, which has not met with the success credited to those used by its neighbor; this company has three shovels in its equipment and it is understood that they will shortly be replaced by larger machines. To make provision for the increased tonnage that the mines at Bingham will send to Garfield, the Rio Grande Western railroad has double-tracked its line into the camp and built a 'high line' to the principal mines; a branch has also



Utah.

been built to the mills mentioned and to the smelter of the American Smelting & Refining Co. This railroad construction has been costly, as it has involved heavy rock-work and some difficult engineering features.

An important event affecting Bingham was the purchase by F. Augustus Heinze of a controlling interest in the Bingham Consolidated Mining & Smelting and, subsequently, in the Ohio Copper company. In securing the latter property, Mr. Heinze has acquired a mine of great value; while it contains a vast amount of sulphide ore, it also takes in a portion of the monzonite zone. Mr. Heinze has announced his intention to provide the Ohio with a milling plant of probably 2,000 tons daily capacity.—— The Utah Apex Co. has been conducting important development work, a feature of which is the driving of a deep adit, to tap the orebodies from 800 to 1,000 ft. under the surface and to form the main entrance into the mine. The company has made provision for an increased output by the construction of an aerial tramway to operate between the mouth of the Andy adit and Carr Fork gulch, pending the completion of the lower adit. The ore deposits of the Utah Apex are not as extensive as those in some other mines in the district, but none have been productive of better ore. The interests controlling the Apex and Utah Development com-

panies have organized the Markham Gulch Milling Co., which is now erecting a concentrating mill at the lower end of the camp. The Utah Development Co., which was formed with the New Red Wing mine as a basis, has recently acquired the Butler Liberal mine. Development during the year has given very satisfactory results.

The Utah Consolidated has greatly increased its ore reserves during the past six months and heads the dividend list in Utah. The company has produced about 19,000,000 lb. copper this year at a cost of a little less than five cents per pound. The directors recently decided to spend a million dollars in the construction of a new smelting plant and, in addition to the treatment of its own ores, the company will engage in custom work. The Utah Consolidated is one of those that will go outside the Salt Lake valley to conduct its future smelting operations.—The Bingham Consolidated has carried on an active campaign of ore extraction and development in its Commercial and Dalton & Lark mines, so that the management is able to report that the ore reserves in both mines have been largely augmented.——The United States Co. has kept up the usual production from its properties. The mines of lesser importance that supplied the market with ore were the Fortuna, Montezuma, Last Chance, New England, Standard Copper, and several others. The Bingham-New Haven company paid its initial dividend of $22,600. The Yampa Smelting Co., operating the only smelter in the camp of Bingham, has added to its equipment and has greatly increased the output of its mine.

Next to Bingham, the Tintic district is the most important in Utah. All told, about 7,700 cars of ore have been dispatched from the mines to the smelters and figuring 50 tons as a basis, that means that the output of the camp has been 385,000 tons, or a little better than 1,000 tons per day. Tintic has won the distinction of having more dividend-paying mines than any other district in the State, the Beck Tunnel Consolidated leading with $325,000. It also has the deepest mine in Utah. Deep mining has been the real feature of the year's work, and the results have been most gratifying, proving that the orebodies of the district continue profitable to a great depth. This has been demonstrated in the Centennial Eureka, Mammoth, Lower Mammoth, Eagle & Blue Bell, and Gemini mines. The steady advance in the price of the metals has helped to stimulate mining activity in the Tintic district, more so perhaps, than in any other camp in Utah for the reason that the leasing system has been conducted successfully in many of the older mines, some of which had been idle for a number of years. Leasing was first tried in the old Bullion Beck mine, which has again appeared on the dividend list. Others followed, and through this means new and important orebodies have been discovered. About a month ago the Tintic Smelting Co. was formed; it is backed by some of the strongest mining and financial interests in Utah, and will build a lead smelter in the district, thus affording facilities for the treatment of low-grade ores on the spot.

The output of Park City this year has been approximately 120,000 tons of ore, the mines contributing being: Silver King, 39,915; Ontario, 5,210; Daly-West, 33,600; Daly-Judge, 33,500; Kearns-Keith, 2,330; New York, 350; Jupiter, 320; Odin, 50; Scottish Chief, 100; Little Bell, 5,500; American Flag, 2,639; other properties, 950 tons. Although Park City has been greatly handicapped on account of the caving of the Ontario adit (which occurred about 22 months ago), new developments made in portions of the district not affected have more than offset the evil consequences of this disaster. Although the Ontario company has been energetic in the efforts to re-open the adit, it may take many months yet to clear out the debris and let loose the pent-up waters. Until this is accomplished, nothing can be done toward further ore extraction or exploitation on the lower levels of several of the principal mines. The most important developments of this year have been recorded in the Daly-Judge mine. This company began the year with an indebtedness of $219,000, which has been entirely liquidated, and the treasury of the corporation now contains over $300,000. An initial quarterly dividend of $112,500 will be paid on January 12. New discoveries of a most gratifying character have been made along Bonanza Flat, Thayne's cañon, and Snake creek. Negotiations are pending for the purchase of a control of the Ontario and Daly mines by Jacob E. Bamberger, president of the Daly-West Mining Co., and it is believed that the deal is approaching a consummation.

In the Little Cottonwood, or Alta district, good progress has been made, and the coming year will see the output greatly increased. The Columbus Consolidated Mining Co., which owns the principal mine of the camp, has announced its initial dividend for payment in January, the amount being $45,000. The old Flagstaff and Emma properties, which gave this locality such prominence in the early days, have changed hands, the former becoming the property of the Con. Flagstaff Mining Co., and the latter of the Emma Copper Co. Another important deal was the consolidation of the South Columbus and Alta Quincy mines, and the organization of the South Columbus Con., all of which will be shipping mines next year. The City Rocks and Albion are also important mines, which belong to the shipping class. The Albion will be provided with a mill in 1907. There is a movement on foot to secure railroad facilities for the district. Just over the Wasatch range from Alta, and in the Big Cottonwood district, the Mountain Lake Copper, and Big Cottonwood Gold & Copper companies have developed some promising bodies of copper ore.

At Mercur, the Consolidated Mercur Gold Mines Co. continues to be the principal producer. The only other property of any consequence is the Sacramento, which produced about 5,000 oz. gold and 1,276 flasks of quicksilver. The Consolidated Mercur is a low-grade gold proposition and the ores must be handled upon a large scale to be profitable. The average value of the ore treated during the past year was $3.76 per ton and the residue in the tailing was brought down to about $1 per ton. G. H. Dern, the manager, and W. T. Janney, the company's chief metallurgist, after a series of experiments, have reached the conclusion that through a specially constructed slime contrivance, at least 50 cents per ton more can be extracted from the tailing. The directors have ordered the construction of a plant that will cost $25,000. Owing to coal shortage in December the output of the mine was below the normal.

The silver-lead mines at Stockton have been active and ore shipments have been made from the new Stockton Honerine, and Black Diamond mines. The milling plants of the first two were operated a portion of the year. In Park Valley, the Century Mining Co. has conducted the most vigorous campaign and has a good bullion record to its credit. At Ophir, the Ophir Hill mine, owned by W. A. Clark, has maintained its normal output, while the Cliff Mining Co., which took over the Buckhorn mine in the early part of the year, has been an intermittent shipper. This company has built an aerial tramway and is prepared to increase its output at once. In the southwestern part of the State the Utah & Eastern Copper Co. is operating successfully the Dixie mine near St. George. The ore is smelted at the company's own smelter at Shem City.

A new gold camp has been opened in the western part of Iron county and is known as Gold Springs. The camp

contains a population of about 100 people. The Jenny Gold Mining Co. owns the principal property and has a mill in course of construction. Stateline shows improvement over a year ago. Considerable property has changed hands there lately, Los Angeles parties figuring conspicuously in the deals. Some promising lead-copper properties have been developed in the Sierra Madre mining district, near Ogden, and in the Deep Creek district in the western part of Juab and Tooele counties. The coming year will witness unusual mining activity. The construction of the Western Pacific railroad west from Salt Lake and the probable building within the next year of a branch of the San Pedro, Los Angeles & Salt Lake railroad to Ely, Nevada, has had the effect of turning attention that way.

The Gold Mountain district has two producing mines of some note—the Annie Laurie and Sevier Consolidated. The latter is equipped with a new cyanide mill able to treat 100 tons of ore per day. Outside of these mines mining operations in this district are limited. A new

Map of Arizona.

copper smelter, the property of the Utah Smelting Co., has been established near Ogden; it is equipped to treat 200 tons of ore per day.

According to the latest estimates reported by the various metal buying and selling agencies the following is the result of the year's operations:

Gold 476,976 oz. at $20.67 per oz.	$ 9,851,091
Silver, 15,981,315 oz., at 66.585c. per oz.	10,629,546
Copper, 67,303,367 lb. at 18.95c. per lb.	12,744,988
Lead, 115,018,811 lb., at 3.635 per 100 lb.	4,480,310
Zinc, 6,472,734 lb., at $6.153 per 100 lb.	398,267
Quicksilver, 1,276 flasks at $42.50 per flask	54,188
Total	$38,161,393

Owing to the fact that it has been impossible to properly segregate some ores coming from adjoining States it is not proper that all the metals shown in the foregoing should be credited to Utah mines. The ore-selling agencies indicate that the approximate amount belonging to other States should be at least $5,000,000, leaving to Utah mines a balance of a little more than $33,000,000.

Dividends were disbursed by 22 mining companies in Utah during 1906 as follows:

At Tintic; Beck Tunnel Con., $325,000; Bullion Beck, $40,000; Carisa, $30,000; Gemini, $200,000; Grand Central, $187,000; Mammoth, $140,000; Mountain View, $12,554; Swansea, $18,000; Uncle Sam Consolidated, $50,000; Victoria, $125,000; Yankee Con, $42,500.

At Bingham; Utah Con., $1,350,000; West Mountain Placer, $2,483; Bingham-New Haven, $22,600; Petro, $32,000.

At Park City; Silver King, $800,000; Daly West, $432,000.

At Fish Springs; Utah mine, $34,000.

At Mercur; Consolidated Mercur, $100,000; Sacramento, $40,000.

At Bingham and Tintic; United States, $1,099,907.

At Frisco; Horn Silver, $80,000.

Bisbee, Arizona.

The Discovery in the Denn-Arizona.—Another in the Hoatson Shaft.—Scarcity of Fuel at Mines and Smelters.—New Appointments.—Progress at Tombstone.

From the standpoint of discovery the past three weeks have constituted a brilliant period in the history of the Warren district, because during that time orebodies were found in two different shafts, which will add two more mines to the list of producers. The strike of ore at the Denn-Arizona shaft, and the subsequent proof of a rich deposit, occupied local attention for a couple of weeks, but during the past few days interest has been centred in the opening up of an orebody at the Hoatson shaft of the Superior & Pittsburgh property. On Monday morning a round of shots exposed a half-face of oxide and carbonate ore on the 1,100-ft. level of the Hoatson. The ore came in such a way that it was evident a mass of it had been found, and on the very next round the full width of the drift was in ore. Work was pushed, and on Wednesday morning a cross-drift, at an angle of 50° to the one in which ore was first cut, broke into a full face of the same stuff. Both drifts are still in the formation, and judging from the nature of the ore, and the trend, the management feels confident that a body of large dimensions has been discovered. At the Denn-Arizona, 51 ft. of ore have been passed through on the 1,000-ft. level, and the last 19 ft. have averaged a little over 16% copper. About the time that the ore was encountered on the level, the shaft had reached the 1,100-ft. mark, and a shift of men went to work immediately to cut a station from which a drift will be run to tap the orebody at the lower level. The station is about completed, and within a few days the drift will be started in a southerly direction.

At the Shattuck-Arizona the production is being increased, and it is estimated that the smelter returns for December will show a total of 1,250,000 lb. copper. The new office building, to take the place of the one destroyed by fire, has been completed, and is now in use. The Allis-Chalmers hoist is in operation, and giving entire satisfaction. At the Copper Queen property, the scarcity of fuel has caused embarrassment, and it was found necessary to close down the shafts on the first three days of the week. A limited supply of coal arrived on Wednesday, and by practising the strictest economy it has been possible to keep all of the shafts going since that time. The machinery that was in use at the old Holbrook shaft, when it caved several months ago, is now being removed to the new shaft, and it is believed that it will be possible to hoist ore within the next three weeks.——The scarcity of fuel has also been felt at the smelters at Douglas, but on Friday the management of the Copper Queen Co. stated that there was enough oil on hand to supply their reduction plant for six days, and that an additional supply was assured.——The appointment of L. D. Ricketts as manager for the Greene-Cananea Co. and his consequent resignation from the active management of the

Old Dominion Company at Globe, has caused a report locally to the effect that Gerald Sherman, assistant superintendent of the Copper Queen Co., will take charge of affairs at Globe. While the appointment would not be a surprise, as Mr. Sherman has proved himself an able man, no confirmation from an official source can be obtained.

The Chiricahuaua Development Co.'s property in the Paradise district will be operated again in the near future by a company in which Thos. F. Cole will have a controlling interest. —— In the Huachuca mountains, development work is being prosecuted, but nothing unusual has occurred. At the Empire State property, north of Bisbee, the tunnel has been driven into lode-matter and iron ore, which has always been considered a good indication. —— Reports from Tombstone are to the effect that everything is progressing about the same as usual, and a small increase in production is promised for this month. The new battery of boilers that was erected a couple of months ago has proved adequate to handle the water, and development work is being prosecuted under correspondingly better conditions.

Mexico City.

The Greene-Cananea Merger.— Other Deals on Foot.— Government Control of Railroads.— A Big Consolidation.— Importance to the Mining Districts.

Great as has become the Greene Consolidated Copper Co. in its seven years of existence, and development work by which it has become one of the greatest copper properties in the world, and adding to the marketable supply of that metal at the rate of 6,000,000 lb. per annum, its outlook for an even more brilliant future has certainly been assured by the merger, which was consummated by the Greene company's vote of approval on December 18, whereby the Greene Consolidated Copper Co. and the Cananea Central Copper Co. have become one company, known as the Greene-Cananea Copper Co., was organized under the laws of Minnesota, with the principal offices at Duluth, where articles of incorporation were filed December 22. The new company will have a capital of $50,000,000, divided into 2,500,000 shares of a par value of $20 each, of which 1,500,000 shares will be exchanged for the Greene Consolidated Copper Co. stock and 1,000,000 shares for that of the Cananea Central Copper Co. This combination was brought about by W. C. Greene, J. D. Ryan, and T. F. Cole obtaining controlling interest in the two companies, and forcing the issue; of the new company T. F. Cole will be president, and W. C. Greene vice-president. In addition to Messrs. Ryan and Cole there are associated in this move H. H. Rogers, John W. Gates, and others allied with the Amalgamated Copper Co.'s interests, so that whether or not this latter company may eventually assume control of the Cananea company, certain it is that the financial condition of the new company will be easier, and when improvements are desired by the Greene-Cananea Copper Co., it will probably not be embarrassed by a lack of money as was so frequently the case with the Greene Consolidated, and already there is talk of the new company more than doubling the present capacity of the Greene Consolidated Copper Co. plant. It is furthermore stated that Cole & Ryan are also negotiating for the entire holdings of the Greene Gold-Silver Mining Co., which includes the Consuelo in Chihuahua (just purchased from Corrigan & McKinney for $1,500,000 gold), La Bufa Mining Co., La Dura, and the Yaqui Copper Co. (also recently acquired), together with the smelting plant at Guaymas, Sonora, and the old Federal smelter at El Paso, and concessions for smelters at San Blas, Mazatlan, and Guadalajara. Control of this company, and the building of the smelters for which it holds concessions, taken with the Cananea plants, would give to Ryan & Cole, and their associates, almost complete control of the smelting business of the States of Sonora and Sinaloa and the greater part of the west coast of Mexico.

Most important to the mining interests of Mexico, as well as to all other business interests, is the deal just concluded, and approved by the Federal Congress, whereby the Government obtains control of the Mexican Central railroad. The Government already controls the Mexican National, the International, and the Interoceanic, and these will be merged with the Mexican Central railroad, and a new holding company will be organized with a capital of $225,000,000 gold, of which the Mexican Government is to hold $113,000,000. This combination, with branches in course of construction, comprises 10,000 miles, and includes the principal railroads of the Republic, except the Mexican, from Mexico City to Vera Cruz, and the new roads building, of the Southern Pacific from Guaymas to Guadalajara, and the Mexico, Kansas City & Orient railroad across Chihuahua and Sinaloa to Topolobampo. This merger furthermore means the cutting off of a number of parallel lines, and the consequent building of a number of important branches, particularly needed in the mining districts.

Republic, Washington.

Review of Mining Progress in the Northwest.—Eastern Washington.—Republic District.—New Railroads and Power Plants.— Wolframite.—Palmer Mountain Enterprises.—Chesaw Mines.

Eastern Washington has witnessed an awakening in mining during the past year, and several important developments have been recorded, although Ferry county has been handicapped by the lack of a suitable method for treating the dry ores of Republic, the principal camp. During 1906 the Pearl Con. Co. deepened its main shaft and did some development work on the Lone Pine vein. At Belcher camp, 12 miles north of Republic, the Belcher Mtn. Railway Co. has constructed a narrow-gauge railroad eight miles up Lambert creek, from the Washington & Great Northern Railway to the Belcher mine. The Winnipeg Co. drove about 250 ft. of tunnel to connect with the Belcher Mtn. Railway and is developing the Hawkeye mine from that level, at a depth of about 250 ft. The ores of the Belcher and Winnipeg mines are principally pyrite, containing gold and silver, with signs of copper. The Oversight Co. made a fine showing in 1906. Besides driving on both sides and cross-cutting the Oversight vein in the No. 2 workings, the No. 3 adit has been driven 50 ft., and both are connected by a raise. Since making the connection a large body of ore has been opened up and several shipments have been made to the smelters. The Pin Money vein was encountered last fall, and a shaft, following the pitch of the vein, was sunk 50 ft. Assays from this vein ran high in gold and cobalt, in the form of smaltite. The Copper Key Co. drove an adit 500 ft. long and lateral drifts aggregating about 600 ft.; also a separate adit to strike the orebody 100 ft. below the upper workings. In the lower workings a fine body of quartz ore was encountered that assayed well.

The Bortle Copper-Gold Co. was incorporated a few months ago and has since then done a good deal of exploratory work, sinking shafts, in one of which a fine body of sulphide ore was uncovered. The sale of the Monitor group of claims on Missouri Mtn. has had a stimulating effect in the Lambert creek district. In October the Dominion Copper Co., of Greenwood, B. C., bought the Adelphi group of claims on LaFleur Mtn. for $30,000 and has begun active development work. This

property is situated near the Comstock-LaFleur group, which belongs to the LeRoy Co., and is immediately south of the international boundary line. The same company purchased the Lone Star and Washington claims of the Reservation Co. and is opening up new orebodies in them. The Mineral Hill Co. after shipping 22 carloads of ore from the old workings, drove about 500 ft. of a new adit and during the coming year will extend it 900 ft. farther into the hill, to tap the vein at a depth of over 400 ft. It is advancing at the rate of 100 ft. per month. The company has a complete equipment, including a six-drill Norwalk compressor. Another adit, higher up the hill, is being driven by hand for the development of other veins. The completion of a fine flume, one and one-half miles in length, and a 150-ton smelter, at Keller, has had an encouraging effect in the southern part of Ferry county. Keller is situated in the San Poil district, with many promising properties in the neighborhood.

The big stretch of country east and west of the San Poil river, 50 miles from Republic to Keller, was a vast scene of excitement last summer, when the Spokane & British Columbia and the Washington & Great Northern railway companies began cutting rights of way through the beautiful San Poil valley; but injunctions brought about a cessation of work and a period of depression. Nevertheless, a number of properties have started work; among these are the Umatilla, Gold Cord, Silver Hill, Iconoclast, Humboldt, Byrne, and Manilla, in the San Poil district, the Congress mine on Bridge creek, the Mountain Boy, and others at Park City. Last November the Colville Mining & Smelting Co. was organized to take over the Mountain Boy mine. While Republic is its principal place of business, provision is made for offices at New York and London. During the year F. M. Gates, the former owner and now local manager, drove 200 ft. on the Mountain Boy vein and developed some rich galena and antimonial silver ore. During the year the Meteior Mining Co., at Meteior camp, has extended its adit about 500 ft. and tapped the vein at 660 ft. from the portal at a depth of 325 ft. The vein is four feet wide between walls; a streak on the foot-wall from 1 to 10 in. wide, shows native gold and ruby silver.

One of the most important mining events in the State of Washington was the discovery in the Cascade mountains of wolframite, the most valuable of tungsten minerals. In the fall of 1906 the Tungsten Con. Co. was organized, with Loomis, in Okanogan county, as its principal place of business, and during the following winter and last spring substantial buildings have been erected, trails were opened and the tungsten mine was partially developed. One vein as disclosed in a 60-ft. tunnel, is from 1 to 7 ft. wide; the other is from 10 to 24 in. wide. In a quartz gangue the proportion of wolframite is 10%. The concentrate, as sent to Pennsylvania, will yield 73% tungstic acid. It is probable that a concentrating plant will be built next summer.

The Palmer Mtn. tunnel, already 4,000 ft. long, is to be driven 4,600 ft. further. Work almost ceased for two or three years, but the energetic manager, John Boyd, secured the capital necessary to complete the undertaking. Last year, after building 5,435 ft. of flume, the Palmer Mtn. Power Co. erected a $50,000 electric plant, including a 750-h.p., three-phase, sixty-cycle, 6,600-volt, alternating generator (made by Allis-Chalmers), driven by a turbine, working under a 370-ft. head. An aluminum transmission line was built from the power-house, on Touts Coule creek, two miles to the mine. The line was continued to the town of Loomis, which is now lighted by electricity. During the year the company installed a saw-mill with a capacity to cut 20,000 ft. of lumber per day, driven by electric power. The foundations for a 100-stamp mill were completed. Above the millsite a reservoir of 7,000 gal. capacity was built. The mine was equipped with three Temple electric air-drills. The 12-lb. rails in the adit were replaced by 25-lb. steel rails. A number of new buildings were constructed. At the Copper-World Extension mine, also on Palmer Mtn., a body of ore over 30 ft. wide, having a large excess of iron and assaying well in gold, silver, and copper, was intersected on the No. 2 level in the early part of the year, and since then the main shaft has been sunk to the 300-ft. level, and another cross-cut driven about 200 ft. toward the lode. The Judge Mining Co., an Ohio corporation, bought 23 claims on Palmer Mtn.; they are traversed by numerous veins of quartz, bearing gold, silver, copper, and lead. Some of the ore exposed in the exploratory workings carries native gold and is extremely rich.

The Kimberley Development Co. was organized to take over 14 quartz claims on the eastern slope of Palmer Mtn., of these the most important are the Kimberley and Buzzard claims. On the latter a shaft has been sunk to a depth of 100 ft.; at the bottom the vein is seven feet wide. A tunnel will be extended to intersect the Kimberley vein at a depth of 350 ft. Small shipments of ore will be sent from this property to the smelters as soon as the Victoria, Vancouver & Eastern Railway begins receiving freight at Oroville. Negotiations are on foot with the Similkameen Falls Power Co. for electric power and for the purchase of machinery.

In the vicinity of Palmer Lake, and northward, along the Similkameen river, mining activity has increased steadily during the past three years, and now that railway transportation will be available every effort is being bent towards getting ready to ship ore. Electric power from the Similkameen Falls Power Plant will be available early in 1907, and this will stimulate mining throughout this part of the State.

The Q. S. Co., since tapping the orebody in its main adit last year, has driven the latter 235 ft., cutting through ore of commercial value the entire distance. A few months ago the company stopped hand work, to await the installation of power, and at that time had not reached the back wall of the lode. It abandoned the intention to build a tramway, preferring to drive an adit to cut the ore at a depth of 2,000 ft. on the lode. This new work was started recently. The company is installing a new turbine wheel and electric plant on Sinlahekin creek, about two miles distant from the mine, to develop 1,000 h.p., with which to operate a battery of machine-drills, to be used as soon as the adit enters hard ground. The Q. S. ore carries an excess of iron and sufficient lime to make it self-fluxing. Copper occurs in the form of chalcopyrite. There is talk of establishing a custom smelter in the neighborhood.

Chesaw, a promising camp but retarded by its isolation, has been bidding for favor, and has succeeded in securing some capital. The Grant group of six claims has a fine vein of pyrrhotite, with ore of shipping value in gold and copper. Last fall a shaft went through 16 ft. of copper-gold ore, and in November last a deal was closed by which George A. McLeod, of Grand Forks, B. C., took over the group for a consideration of $40,000. Already a pile of ore, estimated at 300 tons, has been placed on the dump. The near approach of the Victoria, Vancouver & Eastern Railway has invested Chesaw with bristling energy, and a number of other prospects are being developed actively; among them are the Poland China, Mad River, Olentangy, Bimetallic, Jack Pot, Ben Harrison, Interstate, Saranac, Old Germany, Opal, Butcher Boy, and Bluffton. A new hoisting plant has been installed at the Saranac. The shaft and underground workings of the Poland China were re-timbered and a stamp-mill is talked of. The Interstate mine is to be supplied with a power plant.

Mining Summary.

ALASKA.

Development is proceeding rapidly at the copper mines on Latouche Island. One hundred men are at present employed, 58 by the Reynolds-Alaska Development Co. at Boulder Bay and the rest by the other companies at work on the island. The Reynolds-Alaska Co. will ship heavily next year; ore is piling up on the dump, but it cannot be taken to water until a tram is built, which will be done next spring. An electric power plant has been installed, and now four compressors are driving the drilling machinery. Work will be pushed steadily all winter. The group belonging to the Development Co. is known as the Iron Mountain group. An adit a mile long was driven on the lode, and then it was cross-cut, exposing an enormous orebody. Of the other properties on the island, Beason's mine is shipping steadily, although it is worked by hand labor alone, while extensive development work has been done on the Blackbird group, the Singer, and the Buzzard.

CALIFORNIA.

HUMBOLDT COUNTY.

The beaches between Humboldt bay and the mouth of the Klamath river are being prospected, with a view to shipping the richest deposits to the Oriental Reduction Works, now building at Portland, Ore. Besides being a fluxing material the beach sand is rich in gold and platinum. Fred H. Hazard will direct the work of prospecting, in order to locate and explore the richest and most accessible deposits.

INYO COUNTY.

The great Greenwater consolidation, taking in the Greenwater & Death Valley Co., controlled by the Schwab interests, the United Greenwater Copper Co., and the interests controlled by C. Brock and his Philadelphia associates, is based upon the following distribution of stock. Greenwater & Death Valley Co., 68%; United Greenwater, 18%; the Brock syndicate, 14%. The Schwab interests will control the directorate. The site for a smelter has been chosen at Ash Meadows, Nev., about 30 miles northeast of Greenwater. Work is to be begun next week on the construction of the railroad from the mines to the smelter site. There are extensive deposits of lime and iron, and every requisite for smelting except fuel, and this will be brought in from the petroleum fields of California. Recent assays give the average of the ore as 12% copper, $6 gold, and $9 silver per ton.

SAN BENITO COUNTY.

During the past five months 35,000 tons of ore has been taken out of the Florence Mack quicksilver mines in this county, near San Carlos peak. A recent test showed that the shale ore ran 51 lb. per ton, which, at 50c. per lb., makes it worth $25.50, while the iron ore ran 54 lb. per ton, and is worth $27 per ton. Three hundred feet of adits have opened up good prospects of both iron and shale ore. There is now enough material uncovered to run a 10-ton furnace regularly, but the weather and the condition of the roads are such that it would be impracticable to build a furnace at the present time, the brick having to be burned on the ground; therefore, the owners have decided to keep on blocking out ore and driving adits until next summer, when it will be possible to put in an adequate furnace and keep it going continuously.

SAN BERNARDINO COUNTY.

At the Kelso mine, situated on the Salt Lake route, 250 miles from Los Angeles, three well-defined lodes have been uncovered, extending for a length of 2,000 ft. and 300 ft. apart. Surface indications show the veins have highly mineralized outcrops containing gold, silver, copper, and lead. A shaft has been sunk 80 ft. A steam-hoist is about to be installed, and work pushed in order to reach the 500-ft. level, where it is believed the three lodes effect a junction.

SHASTA COUNTY.

Foundations for the bridge across the Sacramento river have been completed on the new railroad location on the Pitt river. Grading will be commenced shortly, and construction work carried on vigorously. This railroad will pass through the experimental iron smelting works at Heroult, and follow the Pitt river to the Bully Hill copper district.——Construction has also been commenced on the railroad that is being built from the Quartz Hill mines to the Southern Pacific railroad at Central Spur. This will afford an outlet for the silicious ores, which are in great demand for fluxing purposes at the United States smelter at Kennet.

TUOLUMNE COUNTY.

Rich strikes have been made in several of the mines on the east belt during the past few days. At the Garfield mine, situated less than two miles northeast of Tuolumne, the vein was struck at a point where it is four feet wide and runs hundreds of dollars per ton, outside the rich streak, which is a mass of wire gold. The strike is said to be the best made in this district in many years. A report is in circulation here today that the mine has been purchased outright by a Colorado man for a large sum, but the rumor could not be verified. The Confidence is another mine in which a good strike has just been made. At the bottom of the new three-compartment shaft, being sunk 1,000 ft. north of the old one, the vein, four feet wide, averages $200 per ton. A streak several inches wide will run a great deal higher.——The shaft of the Providence mine, now 1,330 ft. deep, will be sunk another 100 ft.——W. A. Nevills is personally directing operations at the App mine, near Quartz, and will shortly have close to 100 men employed. Forty stamps are pounding on ore, and within a few days the entire mill, 60 stamps, will be in operation.——Work has been temporarily discontinued at the Uncle Sam mine, at Arastraville, owing to the necessity of a larger hoist, which, it is said, will soon be installed and operations resumed. Some good ore was recently uncovered in this mine.——The adit being driven at the gravel property of the Springfield Tunnel & Development Co., at Springfield, is now 250 ft. long, and the prospects are said to be exceedingly good. A Sparks Kroh mill having a capacity of 80 tons per 24 hours has been purchased and will be installed on this property.——The Atlas mine, near Tuttletown, is being unwatered for inspection by San Francisco capitalists.——The Yankee Hill Gold Mining Co. has begun hydraulic mining on its property near Columbia.

Tuolumne, Dec. 31.

NEVADA.

ESMERALDA COUNTY.

In spite of dispatches from Goldfield that the miners strike is all but settled, George Wingfield, now in San Francisco, insists that he has not received any word that might indicate that the strike is any nearer settlement than it was a week ago. He contends that while operators may be on the verge of a friendly disposition of the affair, so far as the Goldfield Consolidated people are concerned there is no new development. He adds that the leases on the merger properties expire in a few days, and that the Consolidated management is prepared to shut down all the mines, to work them on their own account later on. This attitude in regard to the strike situation has caused many mining men to believe that the market in southern Nevada securities is being beared, and that when the time is ripe the trouble with the miners will disappear.

According to official figures the Mohawk mine produced during the month of November $1,066,500 in gold. This does not include ore in transit or in the hands of the smelters for which settlement has not been effected. The output of the Red Top was $60,000, the Jumbo $30,000, and Combination $80,000. The Hayes-Monette is stated upon the authority of G. H. Hayes to have $1,080,000 stored in the vaults of the John S. Cook bank. Fifty per cent of this value, or a total of $540,000, was extracted in November. The Frances-Mohawk lease also has $30,000 worth of ore stacked at the State Bank & Trust Co., of which 50% was mined in November, according to the estimate of S. Oliver, the manager. This output is not included as part of the Mohawk production for the month.

LINCOLN COUNTY.

Grading has been started to clear the ground for the addition of 20 stamps to the Quartette mill. The old mill on the Colorado river will be torn down and set up alongside the present 20-stamp mill, making a total of 40 stamps, and

enabling the company to crush 140 tons of ore daily. The force of men will be doubled, and a large number of new buildings erected.——The Big Tiger Co. will sink its shaft from 112 to 212 ft. It is the intention of the company to sink to water-level and test the formation before driving and cross-cutting. The mine is situated at the head of Tiger Wash on the east slope of the Crescent range, 100 yards from the road between Nipton and Searchlight. In the New Year's Gift the lode has been picked up in a winze to the east of the fault, and the ore is as good as ever. High-grade shipping ore has been cut and is now being sacked. It assays $35 in gold, 30% lead, and 3% copper.

(Special Correspondence).—Fred Carlsen returned from Philadelphia last week accompanied by B. B. Lathbury, a mechanical engineer, and Dr. Haerer, representing a syndicate of Philadelphia capitalists, who have purchased the control of the Searchlight Consolidated Co. They advised the sinking of a new shaft, on the Oregon claim, at a point where Mr. Carlsen had struck some rich ore on the surface, and two shifts are now sinking a double-compartment shaft which the company intends to send down to the water-level as fast as men and money can do it. The syndicate has ordered a 25-h.p. hoist, and has commenced the erection of the necessary buildings to accommodate the men. The surface showing on the Searchlight Consolidated ground is above the average in this district, and the vein in the 80-ft. shaft on the Oregon shows free gold from the surface to the bottom.——John C. Quinn, an engineer from New York, spent the past week looking over the X-Ray property, which adjoins the Pompeli and was recently purchased by New York parties.——The Quartette Co. is placing foundations for the erection of 20 more stamps, which will double their present capacity.——J. F. Wisner, of New York, has completed the purchase of the Philadelphia group, located on Nob Hill 14 miles north of Searchlight, on the road to El Dorado cañon, and has given a contract to A. J. Peak to sink the main shaft 100 ft. further. Mr. Peak, who has worked on this property for some years, states that there are five distinct veins on the ground owned by the company, one of them six feet wide and assays $10 per ton.——E. P. Tull has made an important strike on the Wash group at Camp Thurman. A lode of quartz three feet wide containing free gold, galena, and copper sulphides has been uncovered, the continuity of the vein is established. Mr. Tull has also found gold in paying quantities on the Red Bird claim.——The Colorado Co. has placed the foundations for the new engines and electrical equipment, which consists of a 25-h.p. hoist and a 60-h.p. engine and large generator. The electrical plant will be used for operating the pumps.

Searchlight, Dec. 24.

NYE COUNTY.

The mines of Tonopah have paid $2,200,000 in dividends since Jan. 1, 1905. Of this sum Tonopah Mining paid $1,200,000, Tonopah Belmont paid $800,000, and Midway $200,000. Ten mines shipped ore in some quantity. The largest shipper, the Tonopah Mining Co., sent out 67,000 tons; Tonopah Extension, 27,500 tons; Tonopah Belmont, 15,300 tons; Montana Tonopah, 4,650 tons; Midway, 4,000 tons, and West End, 1,000 tons. Macnamara, North Star, and Jim Butler shipped 1,600 tons altogether, and miscellaneous shipments of 275 tons more brought the total shipments up to 121,375 tons for the twelve months. The work of the year enabled the management of the Tonopah Mining Co. to prove the Mizpah lode. Development of the Valley View vein is proceeding at 600 ft. depth. Both the Mizpah and Valley View lodes are reported to be improving with depth. The Tonopah Mining Co. has completed a new mill of 100 stamps at Millers, 13 miles from Tonopah. The Midway mill has also been purchased. The output of the two mills will enable the company to pay $5,000,000 in dividends during 1907. In the last twelve months the Belmont has widened the shaft to three compartments, and has opened the mine from the 500 to the 1,100-ft. level. The Montana Tonopah is erecting a 40-stamp mill that will be completed in the spring. Dividends were passed because of the cost of mill construction and the equipment of the mine. The Tonopah Extension Co. has found the lode 1,200 ft. west of the shaft, and has developed a body of ore 45 ft. wide. A 100-stamp mill will be erected this year. The West End, the Macnamara, and Jim Butler mines entered the producing class in 1906. When the mills now in course of construction are completed the output of the Tonopah district will be enormously increased.

Both the Pike's Peak and Little Pittsburg groups of claims in the Wonder district have changed hands, L. B. Hahn, of Goldfield, and associates having purchased them. The price paid for the Pike's Peak was $60,000, and for the Little Pittsburg $25,000. The former group adjoins the Queens on the north, and consists of eight acres, the lodes and formation being similar to those found on the Queens. The surface ore assays from $50 to $300. The Little Pittsburg group consists of 80 acres, adjoining the Jack Pot and Queens on the east.

WASHOE COUNTY.

An important deal has been closed by which F. A. Morath, of Colorado Springs, has acquired large interests in the Rocky Hill Co., operating 17 miles south of Reno. Exploitation on a large scale has been determined on, the capacity of the mill will be doubled and the force now at work greatly increased. More than 5,000 ft. of underground workings have been advanced and large orebodies disclosed carrying average values of from $10 to $20 per ton, easily treated at the stamp-mill and cyanide plant now operated by the company. This ore can be mined and milled at a cost not exceeding $2 per ton, and there is sufficient ore to run the plant at double its present capacity for several years. During the time the deal was being negotiated a discovery was made at the bottom of the main working shaft, in cross-cutting the vein, the lode widening out to six feet between well-defined walls, and giving high assays.——The Reno-Mispah mine situated 2¼ miles north of Reno, has been aggressively developed during the last six months, and there are now disclosed several strong veins carrying milling ore. Average values of $5.50 per ton were encountered in the upper adit, the ore concentrating about six into one. In the lower adit several stringers have been cross-cut carrying from $50 to $100 per ton in gold. In the face of the drift three feet of good milling ore has been cut, assaying $20, and carrying sulphides in large quantities. The property is equipped with a gasoline engine and air-compressor, a blacksmith shop, and one of the most completely equipped assay-laboratories to be found in the State.

SOUTH DAKOTA.

CUSTER COUNTY.

(Special Correspondence).—A number of changes have taken place since my last letter. First, I have to report the sale of the Granite Reef group of mines to R. G. Galespie of Pittsburg, Pa., for $20,000 of which $1,000 was paid down and the balance due on March 14, 1907. This group of claims is situated about two miles southeast from Custer city, and consists of ten full claims, three fractions, a mill-site and water-right. The property is developed by shallow shafts on all the claims and one adit that penetrates the mountain to a depth of 300 ft., cutting a vein of good ore 12 ft. wide. The vein is vertical between walls of quartzite and slate. Seven men are now engaged in sinking from the adit level. Dan. McGonigal, of Custer, is superintendent. The Granite Reef was formerly owned by C. W. Robbins, James Demereau, and Judge A. T. Feay, of Custer.—The Lillian Belle group of claims was also sold about the middle of December and was purchased by the same party that bought the Granite Reef, for the sum of $7,500. This group consists of seven claims and is developed mainly by an adit 130 ft. deep, which cuts a vein 25 ft. wide. This group joins the Granite Reef on the north and this purchase consolidates the two properties. The former owners were Chas. Harbach, Chas. Smith, John Malon, W. Palmer, all of Custer. D. McGonigal is superintendent.——The third sale to be announced during the months of November and December was that of the New York & Custer, formerly known as the Newark group, consisting of 21 quartz claims, and one 80-acre placer claim. The property is situated at the mouth of Crow creek, about four miles due west from Custer. The company now employs 17 men, who are sinking a shaft on the Newark, and will employ more good miners as fast as they can be got. Chas. Waite is general manager, and Dan. Baker is the superintendent of the mine.

Custer, Dec. 24.

Personal.

W. C. HAND is inspecting mines in Siberia.

S. J. DENE has returned to London from the Sudan.

C. A. BOHN, of Mexico City, is visiting friends at St. Louis.

D'ARCY WEATHERBE is at London, on his way to South America.

FRANK H. PROBERT is examining mines in Inyo county, California.

C. M. FULLER has returned from Louisville, Kentucky, to Denver.

BEN. S. REVETT leaves San Francisco for New York on January 7.

ARTHUR L. WALKER will return to San Francisco about January 21.

F. LYNWOOD GARRISON has returned to Philadelphia from Mexico.

C. EVERARD ARNOLD has left Ely, Nevada, and is now at Salt Lake.

FOSTER HEWETT, of Pittsburg, passed through San Francisco on his way to Arizona.

BENJ. B. LAWRENCE has been appointed Western manager for the Lanyon Zinc Company.

JESSE C. SCOBEY has been at Denver for a few days, on a visit from Washington Camp, Arizona.

W. W. BRADLEY has been engaged as engineer for the Ventanas Con. Co., in Durango, Mexico.

W. W. WISHON, who now lives at Los Angeles, has just recovered from an attack of typhoid fever.

WALTER H. WEED is leaving New York to examine mines near Sombrerete, in Zacatecas, Mexico.

J. R. FINLAY has moved from Colorado Springs to New York, where he has an office at 71 Broadway.

WILLIAM W. MEIN, manager of the Robinson mine, at Johannesburg, is visiting his home at Oakland.

JOHN HAYS HAMMOND and A. C. BEATTY are expected in San Francisco at the end of the current month.

A. W. WARWICK has returned to Denver after an absence of nine months in Mexico. He will return thither shortly.

ARTHUR W. STEVENS, superintendent for the Boise King Placers Co., in Elmore county, Idaho, is visiting relatives at Chicago.

LEWIS C. PARKER has just returned from Montana with his family to Los Angeles and left for Jerome, Ariz., on December 31.

THEO. L. LAMMERS, of Spokane, Wash., has been appointed general manager for the Panhandle Smelting Co., Ltd., of Ponderay, Idaho.

A. P. ROGERS is on his way from Los Angeles to New York, whence he goes to Colombia, to examine gravel deposits. He will return in April.

R. B. STANFORD, having regained his health, has resumed his position as manager for the Siempre Viva Mining Co., at Bluefields, Nicaragua.

ROBERT H. RICHARDS is at work writing an appendix to his book on 'Ore Dressing,' to bring it up to date. He will be glad to receive information concerning new improvements in machines and mill-plants.

ROSCOE H. CHANNING JR., who has resigned as general manager for the Utah Consolidated Mining Co., has been appointed president of, and general manager for, the Cerro de Pasco Mining and Railroad companies.

L. D. RICKETTS, who has been consulting engineer to the Greene Consolidated Copper Co. for the past three years (in addition to his regular work with Phelps, Dodge & Co.), has been appointed general manager for the new Greene-Cananea Company.

S. J. GORMLY, formerly superintendent of the blast-furnace department at Anaconda and later superintendent for the Bingham Con. Co., at West Jordan, Utah, recently visited Anaconda and Butte, where he employed a number of furnace-men to assist him in his new work as metallurgist for the Cerro de Pasco Mining Co. at Lima, Peru. Mr. Gormly left for Lima on January 2.

E. G. SPILSBURY broke his left leg and left arm by accident in stepping off the porch of a mine boarding house, on December 20; he was taken to a hospital at Nogales, Arizona, where he is receiving the best of care. Both breaks are simple and clean, and there is no danger of any sort. He is resting comfortably and the doctor expects to have him up and out of doors in a few days. His son, Persifor, came from Cananea to be with him.

JAMES B. RISQUE, recently underground superintendent at the Calumet & Hecla mines, has resigned his position there to take that of general manager for the Utah Consolidated Mining Co., with main office at Salt Lake City, Utah. The property includes the Highland Boy mines, at Bingham, and the Highland Boy smelting works, at Murray. Mr. Risque goes to his new post as an all-round mining man, familiar not only with mining, but also with the concentration, the milling, and the smelting of ores, and with the details of business management.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

REGULAR stage service, twice a week, will be maintained this winter between Valdez and Fairbanks. The new winter trail saves fifty miles over the old one.

A STATEMENT of the value of the various industries in Alaska shows that the fisheries lead all others, the production from 1878 to 1905 aggregating $96,000,000.

QUICKSILVER is produced in Utah, to the extent of 1,276 flasks per annum. It comes from Mercur, where cinnabar occurs in association with gold deposits. Texas and California are the only other States producing quicksilver.

ALTHOUGH 1 lb. of good coal is capable of evaporating 15 lb. of water, in practice this is never attained, the highest under careful test being 12.9 lb.; in the every-day work of an ordinary mine plant from 5 to 7 lb. would be the average.

IN sampling the bottom of a level, great care must be taken to prevent wrong results due to infiltration of fine rich stuff dropped by the cars or from the roof. Similarly, by washing the ore a misleading result may be obtained because it removes the fine stuff that belongs to the sample.

COMBUSTION is neither more nor less than oxidation, the chemical union of other elements with oxygen. This union takes place at varying rates; the extreme on the one hand being the explosion in the gas, oil, petrol motor, or gun; while as instancing tardy action we have the rusting of iron and the drying of paint.

QUARTZ ORE containing gold is being broken at 4,145 ft. in the Victoria Quartz mine at Bendigo, Australia, but the returns are not high, 112 tons yielding 68 oz. 12 dwt., that is, a little over 12 dwt. per ton. The ore of the saddle reef is 8 ft. wide and it will pay to stope, but a great deal of expensive exploratory work must be paid for as well, out of any profits now secured.

AFTER the rivers freeze all mail to the interior of Alaska and Nome and St. Michael goes by way of Valdez. From here it is taken by two routes inland, the one reaching Nome and St. Michael via Fairbanks and the other via Eagle and Tanana. The mail via Fairbanks leaves twice a week, Mondays and Thursdays. Via the Eagle route the mail leaves but once a week from Valdez.

A SECTIONALIZED MACHINE, when erected where it was made, may be as efficient as any other form; but it is not so at the end of a long and difficult journey, when rust and rough usage have destroyed the accurately machined surfaces, and parts and connections have possibly been lost on the way. In such cases considerable skill is necessary to construct even a workable machine from the damaged remnants.

THE owner of the loaned specimens may bring suit for their recovery or for their value. If the borrower disposes of them without the consent of the lender, he may be chargeable with larceny or embezzlement. If he uses them as the basis of selling property from which they did not come, he might be liable for obtaining money under false pretenses. The facts stated in the inquiry suggest several methods by which the borrower might succeed in breaking into jail. It might be well for the lender to wait until the borrower exhausts his efforts in this direction.

AS REGARDS the running of machinery, there is little doubt that greater economic efficiency in the production and use of power would be obtained if the results were tabulated and made more apparent, and if the cost of a hundred horse-power spent in raising ore or water were known with the same accuracy as the gold extraction. The data required are easily obtainable, the calculations by no means involved; yet on many mines power is produced regardless of cost, efficiency untested and unknown, the indicator never used.

THE pendency of litigation over laborers' liens does not excuse the performance of the annual work on a mining claim, either by the owner or the lien-holder. Unless one or the other does the work, the claim would be subject to re-location. In the event of a re-location by a stranger, the rights of both lien-holder and original locator would become extinct. It has been held by the Land Department that where litigation is pending relating to mining claims arising out of patent proceedings and adverse claims, annual work is not required to be done. The correctness of this rule is doubtful. In all cases a bona fide attempt should be made to do the work. In no event, however, could this departmental ruling be extended to cases of litigation disconnected with the patent proceeding.

To apportion among a large number of contiguous claims the expense of erecting a stamp-mill on one of them for reduction of ores in an attempt to satisfy the law as to annual work on all the claims would be a dangerous experiment. The object of the law requiring annual work to be done contemplates that such work should develop actually or tend to develop the mineral resources of the claim or facilitate the extraction of ore. A stamp-mill reduces the ore but does not facilitate its extraction or in any sense tend to the development of the claims, particularly those other than the one on which it is erected. If properties are intrinsically or prospectively valuable, the safest course is to protect them by doing the work in an unequivocal way. The amount of money expended over one 'jumped' claim would probably pay for several years' work on all the claims.

THE one who first completes the acts of location required by law would be entitled to the claim. In California, in the absence of a local district rule, recording is not necessary. The location would be complete by marking the boundaries. If *A* marks his boundaries first, and a record is required by local rules, he would have a reasonable time to file his notice for record after marking his boundaries. *B* could not defeat the rights accruing to *A* by making a later location and by a race of diligence place his notice on record first, provided *A*, of course, recorded his notice within a reasonable time. "Reasonable time" is determined by the situation of the mine with reference to the Recorder's office, and the ordinary methods of communication between the two points. Midnight locations are looked upon with disfavor. As between two strangers attempting to relocate the same claim as against the original locator, probably the midnight locator would take precedence over the one made later in the morning. But an original locator resuming work January 1 at the ordinary morning hour of commencing labor would hold the claim against a midnight or early morning locator.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Goldfield Mines.

The Editor:

Sir—We who live at Goldfield think that a grave mistake is made in your editorial of December 15 classing the Goldfield Consolidated Mines promotion with the "affair of Dr. Lyman" and an injustice is done to the Goldfield Consolidated Mines Co. as well as incidentally to the district in general.

One is an instance of the consolidation of rich mines effected by reputable men, the other is an example of the nefarious work of a fakir who used a sham mining deal as an instrument in the perpetration of fraud.

It is the opinion of engineers familiar with the ground that 50 million dollars fairly represents the value proved and immediately prospective, of this property; but granted their estimate is a little high, is there warrant in classing these rich mines and their consolidation with the "affair of Dr. Lyman?"

Then, to quote your editorial, "the purchase of the Combination mine for $4,000,000 does not represent sound judgment—four millions for a mine that has paid only $786,000 in the last 25 months and that is only 300 feet deep looks like a gambler's throw." How is it that in your analysis of this purchase the dominant factor of available ore reserves was overlooked? Again, "When Winslow and Hubbard bought the prospect for $75,000 they exhibited good judgment and they have since profited by the speculative exuberance of their neighbors." Now, how much had the Combination prospect paid when Winslow and Hubbard made their exemplary purchase? Nil. How deep was the shaft? Ten feet. What was the estimated tonnage of available ore? Uncertain; none to speak of.

And yet in your opinion, *ex post facto*, Winslow and Hubbard exhibited "good judgment" in their purchase. Was not this purchase by Winslow and Hubbard much more "like a gambler's throw" and an example of "speculative exuberance" than the recent purchase for four millions of the Combination mine with its extensive development and vast resources of available ore?

In another article in an adjoining column you made the editorial comment that "it is a remarkable fact worthy of note that after 28 years working 35 per cent of the Homestake ore still comes from the surface;" yet the Homestake is a mine of great worth; so, in the dearth of details as to the Combination mine what has the fact that it is "only 300 feet deep to do with the matter? And in the absence of information as to whether the Combination mine was worked for 25 months for a maximum output or for the segregation of a maximum ore reserve, what has the fact that it has only paid $786,000 to do with an estimate of the mine's value?

It is most regrettable, particularly in the present onslaught on Nevada mining interests, that a mine that has produced $50,000 gold per day for 106 consecutive days, and that is prepared to materially increase this rate of production, should be designated an "excuse for one of the greatest gambling affairs on record".

A careful reading of the clear and business-like 'Announcement' issued by the company shows:

First, no treasury shares are to be sold.

Second, the shares issued are confined to the number necessary for acquiring control of the properties which go to make up the consolidation.

Third, a great preponderance of the total capital stock remains in the treasury and inures solely to the benefit of the stockholders.

To a man familiar with the ground, in touch with events and acquainted with the high character and ability of the directors, the Goldfield Consolidated Mines Co. appears to be a clean business enterprise of great merit; moreover, it is of heroic stature and the mine, from its output of gold, is destined to be one of the greatest in history.

FREDERICK S. HARRIS.

Goldfield, December 28.

[No objection can be made to so fair a protest; Mr. Harris evidently writes in good faith and we are glad to publish his letter. Naturally, we do not accept all of his corrections. The affair of Dr. Lyman was not classified with the Goldfield Consolidated promotion; they happened to be contemporaneous events. As to the comparative exercise of judgment in the purchase of the Combination prospect for $75,000 and the purchase of the Combination mine for $4,000,000, there is this to be said, that the latter sum is fifty times greater than the former; furthermore, the first has been justified by the logic of events, while the latter remains yet to be proved. All prospects are hazardous, they are matters of judgment rather than estimate, and criticism of the sums paid for them is impracticable, because the purchase is usually based more on instinct (itself the product of experience) than on measurable ore reserves or accurately ascertainable facts. But when it comes to buying mines for big sums of money, it is customary nowadays to estimate ore reserves carefully and to leave as little as possible to mere luck; one is entitled to a mere opinion of a prospect, but one must have accurate estimates, founded on laborious sampling and detailed assay-plans, to pass upon the value of a mine. The 'announcement' of the Goldfield Consolidation is not up to date because it lacks the data essential to a proper prospectus; it is not stated even on whose examination and report the $30,000,000 of ore is based; no estimate is of any value save that of a capable engineer who has gone into the matter fully; the name of such an engineer appears on the prospectus, but not in such a way as to give his personal authority to the statements made.

To compare the Homestake, a low-grade ore deposit several hundred feet thick, with the Combination or the Goldfield Consolidated, containing comparatively small veins of extremely high-grade ore, is to obscure the point. That a mine is producing $50,000 per day is a fact falling far short of justifying a valuation of $50,000,000; the $50,000 is not profit, if two-thirds of it be profit, this performance must go on for 1,600 working days, or five years, to pay back the capital, and for eight or ten years to return the capital and pay a proper interest on it. It is a great mine, but in the exuberance of their speculative activities the promoters have overcapitalized it. This is our friendly opinion, without bias, for naturally we want to see Goldfield and all the other new camps as rich and productive as possible. Our motive in offering criticism is on the surface, it is simply to prevent losses of money that in the long run must seriously injure legitimate mining.—Editor.]

A Curious Occurrence.

The Editor:

Sir—On November 1, 1906, during the first cold snap of winter in southwestern Siberia, somewhat after noon, and after snow had fallen, I happened to look toward the zenith and was surprised to find two suns above me in place of the usual one. The second was inferior to the first in brightness and a few degrees to the west. It had rather the appearance of a cross with a very luminous

centre, altogether too bright for the eyes to more than glance at, and reminded me of the effect produced by looking at the full moon through a wire screen. Around the sun proper was a wide and luminous ring of light, while toward the west was a short segment of rainbow showing faintly the prismatic colors. There was no snow falling at the time, although it is probable that snow was passing overhead in the upper air currents. I have lived in cold countries before, but never saw this phenomenon. Are there not such phenomena as 'sundogs' and is this an example? I cannot say this pertains much to mining, but your valuable paper is also allied with science, under which this observation falls.

H. E. WEST.

Spassky, Siberia, November 20.

[This is what is known as a 'mock sun'; it is a kind of halo, due to condensation of moisture and formation of ice crystals in the upper layers of air.—Editor.]

Tube-Mill Lining.

The Editor:

SIR—I was very much interested in Mr. Drucker's experiences with tube-mill linings in Korea, as described in your issue of November 17, and thought a few notes from our experience of the past two years at Bodie, California, might add a point or two.

The tailing-flow from the stamp-mill of the Standard Con. Mining Co., passes directly through classifiers. The tube-mill is used to re-grind the underflow, or coarser material from the classifiers; with which is also fed dry tailing from the old slum ponds. The tube-mill used is an Allis-Chalmers pattern, about 22 ft. long by 5 ft. diameter, as illustrated by the accompanying photograph.

The first lining used in the mill consisted of special steel plates about 10 by 12 in. area by one inch thick, with a base made so that the entire lining was intended to be interlocking. These plates had a life of four or five months, but as is often the case with castings subjected to grinding action, some of them would wear unevenly and occasionally one would drop out of place. This necessitated stopping the mill and replacing the loosened plates.

The next lining used was in the form of pine blocks, cut from 4 by 6 in. sawed timber into 6-in. lengths, trimmed slightly wedge-shaped (to allow for curvature of shell), and set on end. To place a new set of these pine-block liners, including removal of old blocks, and shoveling out and in of the load of pebbles, required usually about 36 hours. (The tube has only the one man-hole, the cover of which is shown in the photograph.) A set of these liners lasted from ten days to two weeks. Aside from its short life, this lining had the disadvantage (by reason of the vegetable oils contained) of making a soapy mixture with the alkalies present in the cyanide solution (crushing being done in solution). This saponification caused excessive foaming in the batteries and on the plates of the stamp-mill (for after going through the zinc-boxes the solution was re-standardized and returned to the battery storage vat), and also in the tube-mill, launders, and vats in the cyanide plant. After a few sets of these pine liners had been tried, a similar set was made out of blocks of mountain mahogany, a dense, hard wood from the Sierra Nevada mountains. This gave a few days longer life, and the saponification was decreased.

Next we tried a quartz lining similar to the one Mr. Drucker describes, except that there were no steel rails on the inside of the shell. The quartz consisted of selected pieces of chalcedonic vein-stuff, very hard and close-grained, from the mine. This lining was carefully put in with portland cement, and then allowed to set for about ten days. In less than half an hour after starting up, the pounding of the pebbles caused the lining to break. This 'hasty finish' was, at the time, imputed to the quality of the cement used and to the fact that it was not allowed longer to set. Mr. Drucker's experience, however, shows that it was not altogether due to such causes. We next tried silex lining; but while this did not take quite as long to place and for its cement to set, as did the quartz lining, it did not give as long a life as was expected. The silex lining, also, acted similarly to the first steel-plate liners used, giving uneven wear, with occasional dropping out of blocks.

Then, it was decided to try wrought-iron bars, 8 in. wide by 1 in. thick, a quantity of which were on hand, having been used as connecting straps or plates at the joints in the old Cornish pump in the Lent shaft of the same company. It was first suggested to bend into circles to fit the inner surface of the tube-mill shell; but, as we had no machine-shop rolls, and the bending would have to be done by hand in the blacksmith-shop, that idea was dropped. The bars were cut in 15 and 7-ft. lengths (15 ft. being the longest that could be handled through the man-hole of the tube-mill). These were put in, alternating (so as to break joint), lengthwise of the

Tube-mill at Bodie.

tube, and bolted with counter-sunk bolts that passed through the shell. The nuts and washers on these bolts are shown by the photograph. The bolt-holes in each strap are 'staggered'; and, it was not necessary to space them closely, because of the length of the pieces. The liners were all drilled to the same measurements; and, in putting in the first set, holes were drilled in the tube-mill shell to correspond, subsequent sets not requiring further drilling of the shell.

As stated above, these straps or bars were of wrought iron. They give a life of between three and four months, and are easy to change—the entire operation of shoveling the load of pebbles, unbolting old, and bolting new liners, requiring only between 20 and 21 hours. The width of the straps, 8 in., does not allow them to fit closely to the curve of the shell, but that is an advantage, as it has a tendency to turn the pebbles over on themselves, instead of sliding, which action wears out the liners rapidly. This mill has been grinding from 50 to 75 tons daily. The portion of the stamp-mill product requiring re-grinding is principally a tough, hard, chalcedonic quartz.

WALTER W. BRADLEY.

Berkeley, December 10.

A NOVELTY in tin-ore dressing in Cornwall is the use of the Ferraris ball-mill for crushing the ore. A single mill crushes 2,240 lb. ore per hour to pass a 30-mesh screen, requiring seven horsepower.

Progress in Cyanidation During 1906.

Written for the MINING AND SCIENTIFIC PRESS
By ALFRED JAMES.

The making of slime and the treatment of it may be taken as the main directions of improvement in cyanidation during the year. The use of tube-mills has progressed by leaps and bounds, and is now rapidly becoming well-nigh universal, but with the adoption of these machines the question of slime treatment has forced itself into still greater prominence, and as stated by me last year, some of our keenest metallurgists have been attacking this problem, and it is now possible to state that their endeavors have met with a considerable measure of success.

As will be indicated later, progress has also been made in the treatment of difficult ores—including silver-gold ores, antimony-gold concentrate, and cupriferous tailing—and in crushing, roasting, and conveying we are ahead of last year's practice.

It is interesting to note how the treatment of gold ores has overlapped the metallurgy of the other metals. Fine sliming and prolonged cyanide treatment constitute a method that, in many cases, is ousting chloridizing roasting and the old patio process for the treatment of silver ores. Copper ore in Chile is now being leached in a cyanide plant—without cyanide—and the Merton roaster, so successfully introduced in Australia for gold ores, has taken a hold on the zinc industry for the roasting of zinc blende, and for the treatment of the zinc-lead-silver concentrate of Broken Hill. Indeed, one cannot fail to be struck by the way in which names well known in gold-milling, such as Argall, Marriner, and Simpson, have been attracted to the problems presented by zinc-lead ores.

It is difficult to put a finger on any one part of the world as having made the most striking progress of the year. Western Australia still has the pre-eminence. Inventions that may have originated in other countries appear to be more quickly put to definite practical service there than elsewhere, and just as Western Australia has taken the lead in fine sliming and in circulating cyanide solutions through the mill, so now it seems to be the pioneer in slime treatment. Probably the emulation arising from the up-to-date methods of the leading firm of mining engineers on the one hand, and independent managers on the other hand, has tended to place Western Australia in the forefront in the matter of new methods, high extractions, and low costs. Certainly such men as Hamilton, Moss, Nicholson, and Klug, and the gentlemen associated with Bewick, Moreing & Co., have cause for congratulation on the results they have achieved and are achieving, and the adoption of their methods in other regions shows that the industry, not locally but generally, is under an obligation to them, as well as to the alert and progressive West Australian Chamber of Mines, which has published an excellent series of articles by Mr. Robert Allen on ore treatment as carried out at the various local installations.

American practice has chiefly busied itself with tube-mills and slime treatment. Argall, Bosqui, Butters, and Merrill have all been contributing to our advancement by getting out improved methods. In Africa the publication of the results obtained by the brothers Denny at the Meyer & Charlton and New Goch mills has caused much interest, for extraction and output have been increased and cost lowered—mainly by the use of tube-mills. Record gold outputs are again being produced from the Transvaal, which has more than recovered the set-back occasioned by the war.

Crushing.—The tendency to stage-crushing is in still greater evidence. Coarse breakers, fine crushers, heavy stamps, pans, tube-mills, are not an uncommon sequence. With reference to breaking of ore, however, it has not yet been proved that reduction to finer than 2½-in. cube is advantageous for the stamps. Experiments seem to indicate that finer crushing is more expensive than the gain arising from any increase in stamp duty will warrant.

As for crushers, the Gates type still holds the field for big work, but the Bigelow breaker, of the Blake type but with the pitman working in compression and having its weight assisting the crushing stroke, appears to be replacing the other kinds at Kalgoorlie, and to show a lower running cost than either the gyratory or the older reciprocating patterns.

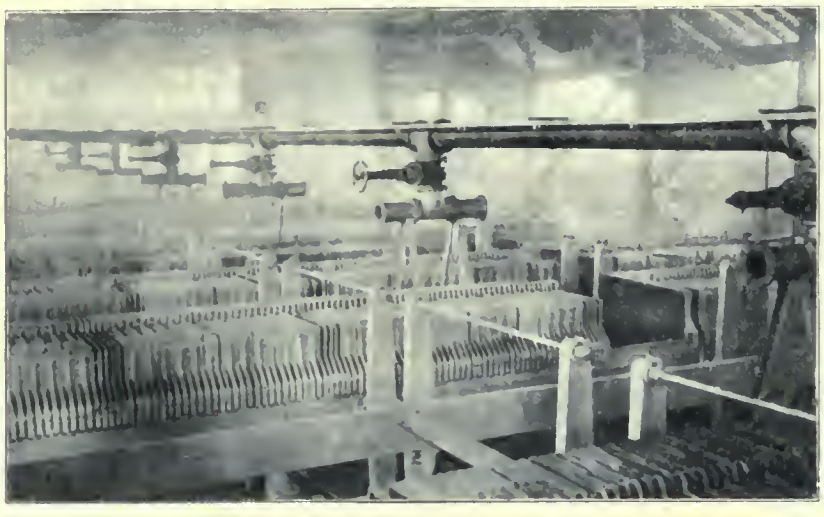
Stamps of 1,500-lb. weight are now in use on the Rand, and it looks as if the limit of weight had not yet been reached. But little has been heard this year of anvil-blocks for mortars, although at the Waihi Grand Junction they seem to have made for a considerable increase in output beyond that originally expected. Judging by output per horse-power, ball-mills would appear to be the most efficient machine, with an output of over two tons per h. p. day on the best types, crushing all the ore through 27 mesh, but the cost of dry-crushing at the South Kalgurli appears to be about three shillings per ton as against roughly 1s. 9d. per ton crushing wet at the Oroya-Brownhill, Lake View, and Ivanhoe. On the other hand the latter crush through very much coarser screening (10, 17, and 15 mesh respectively), reducing the oversized product by their pans and tube-mills.

Fine Grinding.—The tendency has been to use stamps for rough crushing only that is, to substitute coarser screens for those formerly in use, and from the pulp to separate the coarse product and to grind it in tube-mills or pans. There have been no notable contributions to our knowledge this year as to which is the best appliance for this purpose. Tube-mills seem to be generally employed, except at Kalgoorlie, where the roasted ore can be efficiently ground to the required fineness in pans. Not that pans are not effective on raw ore. On the contrary, the Ivanhoe results show very good work indeed, and it is to be much regretted that the comparative tests made at that mine between pans and tube-mills were carried out in such a way as to make the results worse than useless. But it is a matter for serious thought that the Ivanhoe costs for regrinding sand should be only 8½d. per ton treated, when the Oroya-Brownhill, Lake View, and other mills should show a figure twice as high. It cannot well be a matter of pans only, or we should have heard of similar low results from the other companies exclusively employing pans (at the Oroya and Lake View pans are used in conjunction with tube-miils). Is it that the Ivanhoe ore is softer or that the final product is not slimed as fine? The management has recently been very keen on reducing the value in their residue—and have succeeded in doing so materially—and one would therefore expect that they would not overlook the gain from crushing as fine as their neighbors. It is to be assumed, therefore, that the crushing is as fine; but the fact remains that the cost of grinding sand at the Ivanhoe is less than half that of neighboring companies of the same group that employ wet crushing. There is an obvious need of that careful comparative test between pans and tube-mills for which I have so often asked and which I hoped would be undertaken by Klug or Denny. Indeed, it was understood that the latter was making such tests, but nothing seems to have come of them.

Meanwhile I am informed that such a test has been made at Broken Hill with a pan, a wet-grinding ball-mill, a disc-grinder, and a tube-mill, and that the tube has proved itself the best of the lot, but in the absence of details we can only take this statement as the expression of individual opinion. Even if we assume tube-mills to be the best slime-makers there is still the question of

stage-grinding, and it is by no means certain that the preliminary crushing of the coarser particles could not be effected more economically in pans.

The best pan figures have been given above. The following tube-mill data will prove of interest. African costs have been reduced from 8½d. (per ton ground) down to 5½d., of which 1.89d. is for power, 0.7d. for pebbles, and 0.93d. for liners. Mr. Henry Leupold states that silex linings are half the cost and last two and a half times as long as iron liners. The Consolidated Gold Fields made careful tests on manganese steel liners as against silex, with the result that the former were shown to be more expensive and the grinding nothing like as good, owing to the slipping of the pebbles caused by the polished surface of the manganese steel. At El Oro, a 20-ft. mill with 7½ tons of pebbles grinds 125 tons per day of sand for 60 h.p. to such a fineness that 90% will pass 100-mesh and 50% a 200-mesh screen. At Waihi, an 18-ft. mill grinds 77 tons of 20-mesh sand per day, so that 93% will pass 150-mesh, for 37½ h.p. The Waihi is notorious for the hardness of its ore, which ball-mills failed to grind satisfactorily. Their tube-mills do not appear to be run to their utmost capacity, but their figures are interesting as an example in practice of direct tube-mill work, that is, without any return of material treated. The above figures, of over two tons slimed per horse-power, at first sight show a less duty than that mentioned by me a year ago, of four tons per horse-power in Africa, but it must be remembered that the African crushing was much coarser, they having at that time adopted a standard of under two per cent retained on 60 mesh.



Merrill's Filter-Presses at the Homestake.

But apart from the question of comparative cost of work done, tube-mills have shown their distinct economical advantage as well as their capacity for re-grinding. Reference was made last year to the huge additional net profit of £65,000 per year accruing to El Oro Company from this source. At Waihi three 18-ft. tube-mills and 90 stamps have increased the output from 2.89 tons per stamp per day to four tons, and have lessened the value of the residue by 50%. They have improved the extraction by amalgamation from 5 to 7%, and effected a 75% saving in screening. They find also that since the adoption of tube-mills the slime is more permeable and the filter-press charges take less time for treatment, so that the same presses can now deal with 30% more slime than before. The new Barry linings, made on the spot, seem to be most effective and to result in a great saving of cost over the imported silex. One set of linings is stated to last for six months, and a new set is always kept ready at hand and can be replaced in two days. Mr. H. P. Barry makes a great point of having his linings as rough as possible, so as to give a grip to the pebbles, and has modified his doors to effect this also.

At Johannesburg Mr. W. R. Dowling emphasizes the necessity for the complete separation of the sand to be re-ground from the slime in the mill-pulp, and for keeping the proportion of water to sand at as low a figure as possible. He shows at the Robinson Deep a 0.48 dwt. lower residue (formerly 1.26 dwt., now after tube-mill treatment 0.78 dwt.), and an increased capacity of 2,300 tons per month. The Eckstein mines, in addition to the increased output resulting from the tube-mills, show an additional profit of from 1s. to 1s. 6d. per ton (1s. at the Robinson, 1s. 4d. at the Ferreira) resulting from the increased extraction, which has lessened the value of the residue by about half a pennyweight. There are now 58 tube-mills at work on the Rand—and more on order—at 24 different mines, and these 58 tubes at the 24 mines only have increased the amalgamation returns of the whole of the Rand by three per cent.

At present the Knight's Deep appears to have the highest monthly output per stamp—for complete battery—of 7.68 tons per stamp, since reduced by the substitution of different screening to 6.68 tons. In Western Australia the Oroya-Brownhill crushes 7¼ tons per stamp through a 10-mesh screen, and the Great Fingall (1,150-lb. stamps) exhibits an average duty of seven tons per 24 hours through a 12-mesh screen, and the Sons of Gwalia at Leonora (1,000-lb stamps) treats 6.68 tons per head per day through 20-mesh screening.

Another View of the Merrill Presses.

It is estimated that, in addition to the gains already mentioned as resulting in Africa from the use of tube-mills, there is a saving of 30% in equipment arising from the adoption of them in place of obtaining the same out-

put by the addition of the increased number of stamps necessary.*

Amalgamation.—The increased extraction by amalgamation resulting from the use of tube-mills, has been referred to already. At Waihi, amalgamation is carried out on plates set in a large building apart from the mill, sand and slime being treated separately. There is much to be said for this arrangement. Companies circulating cyanide solutions through the mill find a scouring of their copper plates by the cyanide solutions. Denny, at the Meyer & Charlton, proposed to minimize this action if possible by adopting shorter plates, but probably the better method would be to exclude copper plates from the amalgamation apparatus. At the Lake View (Kalgoorlie), for instance, plates are discarded and amalgamation takes place in pans; in that mill 51% of the value of the concentrate is recovered by amalgamation and 46% by subsequent cyanidation.

Roasting.—Thomas Edwards has increased the capacity of his recent furnaces by a parallel system of rabbles, which is stated to promote inter-rabbling. G. C. Klug has adopted this for the Holthoff-Wethey furnaces at the Perseverance, and claims high results. Merton has also modified his furnace by making it a five-hearth roaster, and also of greater hearth-area. The Great Boulder Proprietary has a roasting cost of 2s. 3d. per ton (employing Merton furnaces) reducing an ore going 4 to 5% sulphur down to 0.07% sulphur, as sulphide; with this exception the record of the South Kalgurli type of Merton furnaces does not yet appear to have been improved on, either for cost (2s. 6d. per ton roasted), output (32 tons per diem for small-size furnace, taking 1½ h.p.), or efficiency (3.1% sulphur down to 0.01% sulphur as sulphide; one ton of green wood roasting 11 tons of ore). With regard to the suggestion that I made in this review a year ago of adding, say, two pounds of lead acetate per agitator charge (40 to 60 tons) of roasted ore, Richard Hamilton of the Great Boulder finds that the use of lead salts appears to result in an increased consumption of zinc in the precipitation boxes, as against which he benefits by a saving of roasting fuel, an increased tonnage through the mill for the same labor, a reduction in the value of the residue, and a general feeling of confidence in the ability to set foul roasts all right quickly in spite of fluctuations in natural draft.

Concentration.—There appears to be no great advance made this year in the concentration of gold ores. The difficulty remains that an attempt to concentrate out refractory particles from an ore usually leaves a tailing practically as refractory as the original ore.

It was hoped that fine sliming and the Wilfley slime-table might overcome this difficulty, but the latter machine is by no means perfect and maintenance is a most formidable item. So far the old canvas tables or frames appear to give the best results, but the cost of washing down is very heavy indeed—amounting in certain cases to 30s. or 40s. per ton of concentrate produced. A continuous rough rubber or canvas-belt table, somewhat on the Luhrig or Buss system, might solve the difficulty, though the capacity per unit would necessarily be small; or the old treatment table could have a traveling system of washing pipes worked by a water balance, and thus avoid the expense of so much boy-labor.

The flotation processes are being mainly applied to zinc-lead concentrate at Broken Hill, rather than gold ores. De Bavay and Simpson appear to have made an interesting discovery as to the principles involved in the various flotation processes, which they claim depend on the surface tension of sulphides as contrasted with the gangue, the greasy sulphides when wetted retaining an envelope of air that is expanded by heat, or by vaccuum, or aided by the air entangled in oil, or gelatinous silica, or by flowing the mineral pulp in very thin layers—practically all surface—over inclined tables.

Treatment of Difficult Ores.—Cupriferous tailing with a copper content not exceedining 0.5% is now successfully treated by leaching out the copper with dilute sulphuric acid and precipitating on scrap iron, as described by W. S. Brown.† With ores containing more copper—but not rich enough to smelt—a preliminary roasting of the ore has been found to improve matters. The addition of ammonia to the cyanide solution has been previously suggested and carried out in practice.

Auriferous antimonial concentrate, containing say 20% antimony and arsenic, has been successfully treated by an ordinary careful roast of the ore previously mixed with from 2 to 5% charcoal or coal, followed by a hot acid wash of dilute hydrochloric acid (obtainable by exposing old chlorine solutions to direct sunlight), and then lixiviating with cyanide or chlorine. A variation successfully employed is to roast as above, add salt at the end of the roast, and chlorinate. Both methods have yielded 90% extractions, but have the drawback of requiring very careful roasting.

Slime Treatment.—The brothers Denny have made something of a sensation at Johannesburg by the methods they have applied at their new plants. In these they have adopted the West Australian method of circulating dilute cyanide solutions through the mill and filter-pressing their slime in Dehne hydraulic-closed filter-presses. They claim a recovery of over 94% at a treatment cost, including cyanide, filter-pressing, and disposal of residue (5d), of 1s. 10d. per ton. As this carrying into practice of their proposed treatment scheme was not effected without many prophecies of failure, and as the cost of the installation necessary appears to be less than half that of the method of treatment locally in vogue, it is natural that their work should have received much attention, and as their figures do not seem to be seriously contested, the Denny brothers certainly look like scoring heavily again as the result of their enterprise and foresight, just as they did previously by the introduction on the Rand of tube-mills.

But perhaps the two greatest successes in slime treatment—as being a real advance on established filter-press practice—are the respective methods evolved by Ridgway at the Boulder and by Barry at Waihi. Anyone reading Mr. R. Gilman Brown's article* on the Moore filter, must have noticed the very sloppy badly arranged frames shown in the illustrations. We can understand, perhaps, from these illustrations, one of the reasons for the small success attending the Moore filter in America. At Walhi, Barry has a frame¶ which is much more effective than that shown in the description referred to above, and he has successfully treated many thousands of tons by his method of open-framed atmospheric filtration; but the drawback to this—as to the Moore basket-filter—is the necessity of having men constantly in attendance to clean the frames.

Charles Butters seems to have been alive to the defects of the Moore frame, and has got out one that he appears to be working with considerable success at Virginia City, as does also F. L. Bosqui at Tonopah. Butters, however, has apparently allied himself to the Cassel enclosed type of press, which looks similar to that referred to in a previous paper as being experimented with at Johannesburg unsuccessfully.

The Ridgway machine has now been in use for a year at the Great Boulder, and has treated some thousands of

South African Mines, October 27, 1906.

† *Proceedings* Institution of Mining & Metallurgy, 1906.

* MINING AND SCIENTIFIC PRESS, September 8, 1906.

¶ *The Mining Journal*, September 30, 1906.

tons of slime quite automatically and without any continuous supervision, and Hamilton, who has been testing it alongside his filter-press installation, is so satisfied with the results that he is laying down a plant to treat 500 tons per day—the largest slime plant in the southern hemisphere. The principle of the machine is a number of horizontal plates revolving round a central vertical post, which is really a tube, and to which pipes communicating with each plate are attached. Each plate has an under-filtering surface, and through a portion of its revolution it dips into the slime-pulp. A cake is formed by the application of a vacuum, and the plate in the course of its journey around its axis finds itself next in a water bath, where it remains sufficiently long for thorough washing. The cake is then dislodged automatically into the residue deposit system. This machine is certainly cheaper than filter-presses, both in first cost and in operation, and an equipment to do the duty of an African decantation plant should not only yield higher recoveries at a lower working cost, but should be installed for less than half the expense of the existing system.

Zinc-Dust Precipitation Press at the Homestake.

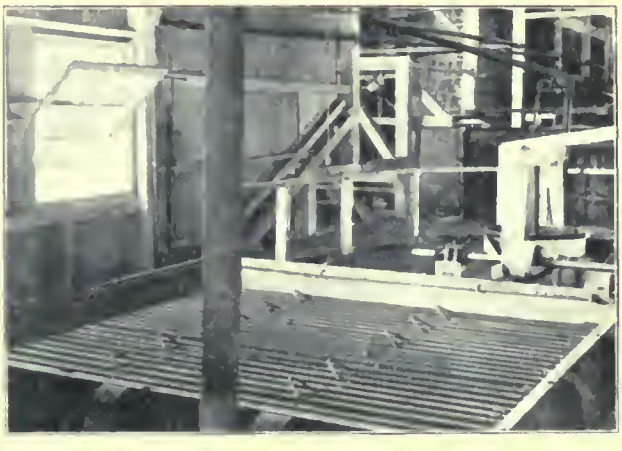
The frame being triangular, the solution and zinc dust, which enter together at the apex, are kept in constant agitation.

Of the other methods referred to last year but little has been heard. C. W. Merrill appears to be still at work on his hydraulic emptying filter-press, but details of successful work have not yet reached me. Philip Argall has a fixed frame and movable tank, but appears too busy at Cripple Creek to be able to give much attention to his slime-filter for the present.

In Western Australia one of the groups had a method of upward percolation of the solutions through the slime-pulp during agitation, but this method does not appear to have been attended with any great success. Generally speaking, it looks as if some direct method of automatic atmospheric filtration would displace both decantation and Dehne filter-pressing, although at the outset it will probably require a higher degree of intelligence for its effective and successful working.

Re-treatment of Tailing.—Not much has been said of the Stark process during the year. It seems to have been most profitably applied to the Crown Reef dump. Is it that there is any special characteristic feature of this dump that makes it suitable for the Stark process?

Butters Press at Virginia City, Showing Electrolytic Precipitation Boxes.



Top View of Butters Press at Combination Mine, Goldfield.

Mercuric Cyanide.—A reference to a test by Butters, on El Oro ore, of a mercury salt added to the cyanide solution, recalls the investigation made by the Cassel company (the owners of the cyanide patents) in 1895 into the use of this salt. They obtained improved results, on some ores, of 3½% greater extraction of the gold and 3% greater extraction of the silver, with a lower consumption of cyanide, but the tests were not continued, as the improved extractions seemed insufficiently encouraging in view of the additional expense of the added salt; but Butters' tests have renewed interest in the subject, and we hope for fuller data.

Moore Filter in the Standard Mill, Bodie.

Costs.—Tube-milling, fine grinding, milling, and roasting costs have been given above. The following tabulated statement of West Australian costs will show the progress still being made in that region by comparison

with those in preceding papers, as well as with those obtaining elsewhere:

Rock-Breaking.

Mill.	Pence.
Lake View	1.71
Ivanhoe	1.87
South Kalgurli (dry)	3.39

Milling.

Lake View	1s. 9d.
Ivanhoe	1s. 9d.
South Kalgurli (dry)	2s. 11d.

Concentrating.

Lake View	6s. 7d. per ton concentrated 9d. per ton milled
Ivanhoe	8s. 0d. per ton concentrated 10d. per ton milled

Roasting.

Lake View	3s. 10d. per ton roasted (concentrate only)
Ivanhoe	5s. 5d. " " " "
South Kalgurli	2s. 6d. " " (all the ore).
Great Boulder Proprietary	2s. 4d. " "

Fine Grinding Sand.

Lake View	1s. 10d. per ton ground.
Ivanhoe	8d. " "
South Kalgurli	1s. 3d. " "

Cyaniding by Agitation.

Lake View	3s. 1d. (Includes 1s. 4d. for KCy and 1s. 2d. for BrCy)
Ivanhoe	4s. 1d. (Includes 11d. KCy, 2s. 6d. BrCy, and royalty 2d.
South Kalgurli	1s. 4d. (Includes 7d. KCy.)

From the above it appears that the agitation treatment, less cyanide and bromo-cyanide, but including power, lime, labor, and supplies, costs roughly 7d. per ton (Ivanhoe 6d.).

Cyaniding by Percolation.

Ivanhoe	2s. 2 d. (Including 9d. for KCy and lime).
Great Fingall	11¼d. (Including 6d. for KCy and lime).

Filter-Pressing.

Lake View	1s. 7d.
Ivanhoe	1s. 6d.
South Kalgurli	1s. 6d. per ton filter-pressed.

The cost of filter-cloths at the Lake View Consols has been under ½d. per ton pressed for every month this year, save once when it was under ¾d.

Total Treatment Costs.

Ivanhoe	9s. 0d.
South Kalgurli	11s. 3d.
Great Boulder Proprietary	11s. 6d.
Great Fingall	6s. 11d.
Sons of Gwalia	5s. 2d. per ton treated.

General.—The battle of the processes at Kalgoorlie is now over. It is admitted that the all-roasting process gives the most profitable extraction, but the good fight made by the wet-crushing bromo-cyanide party, and notably by the Ivanhoe, has been of the greatest service to the industry, and the Ivanhoe's costs are such as to reflect great credit on the management and the staff; but the fine showing made by the South Kalgurli, the Great Boulder, the Kalgurli, and other companies, appears now to have convinced even the former advocates of bromo-cyanide.

EVEN if our education can never be complete, still we ought to strive to develop ourselves along as broad lines as possible. If time and means are limited then an arbitrary narrowing is necessary, and more reliable and useful results are obtained by concentrating the efforts upon one subject than by dissipating them among several. For every carefully investigated and thoroughly understood truth is an accurate and reliable standard by means of which all other knowledge may be tested; whatever stands in direct contradiction is certainly false, even if the errors cannot be clearly demonstrated. Above all should the scientist strive to reach this position, and after mastering one truth should seek to make his circle of knowledge ever wider and wider, with the consciousness, however, that his task is endless and that his aim can never be fully realized.

Quicksilver in California.

Written for the MINING AND SCIENTIFIC PRESS
By CHARLES G. YALE.

The quicksilver industry of California cannot be said to be in a flouishing condition; indeed, the production during the year 1906 is estimated to have been about 2,000 flasks less than in 1905, when the output was 24,655 flasks of 75 lb. each, valued at $886,081. Prices during the past year have been exceptionally low, being from $39 to $40 per flask for domestic orders, and from two to three dollars less for export. Fortunately for the producers, the exports to China and Japan have been exceedingly light, and therefore most of the quicksilver sold has brought the full domestic price. For this reason it is probable that the quicksilver miners have received as much value for their product, even at the lessened price, as they did when more was exported. Mexico, which is one of the markets for this metal, has very materially decreased its demand, because the Mexicans are working their own mines in these days and prefer to use what they produce themselves.

The demand for quicksilver for domestic consumption has been gradually but surely decreasing, since the cessation of silver mining and the general adoption of the cyanide process. It is hoped now, however, that, with the increase in the price of silver, more of the mines of that metal will be operated and an increased demand will ensue for mercury. The yield of the California mines has just about kept pace with the domestic consumption. Some of the smaller mines have stopped work. Indeed it is only the larger ones that can afford to be worked at the present prices, and with the comparativcly small demand. In fact, it is common report that only one mine in this State is now paying dividends, this being the New Idria in San Benito county, which is yielding between 500 and 600 flasks per month. A few other mines, such as the New Almaden and the Socrates, are slightly increasing their output, while others once considered large producers are not doing half what they did a year ago. Several of the mines in San Luis Obispo county have shut down for the present, and very few new ones have been opened in any part of the State.

California has long been known as the largest producer of quicksilver on this Continent; in fact, it was the only producer in the United States until a few years ago, when the quicksilver deposits of Texas were opened. During the last 19 years California has produced 550,154 flasks of mercury, valued as a total at $22,503,131. While of late there is some little increase in demand in the Eastern States, it is not yet enough to affect the market to any great extent. If, however, the silver mines start up again and the amalgamation process is used, there will be more demand for mercury. This demand may be readily met because the mines can easily increase their output, if there is any incentive to do so in the matters of price and consumption. For the present at least, there seems to be very little money in the business of mining quicksilver and it is not probable that any new deposits will be opened unless there is a material change in conditions.

As I am not a smoker I have formed another habit to kill time—namely this habit of general reading, and am accustomed in this way, to make use of my "lost quarter hours" (*e. g.* the kind which elapses between the moment when dinner is announced and when it is served). It would be impossible for me to count the number of occasions on which I have, in this manner, obtained ideas that, in one way or another have helped me to overcome difficulties, which for a long time, had seemed insurmountable.—*W. Ostwald.*

Cobalt, Ontario.

Written for the MINING AND SCIENTIFIC PRESS by T. A. RICKARD.

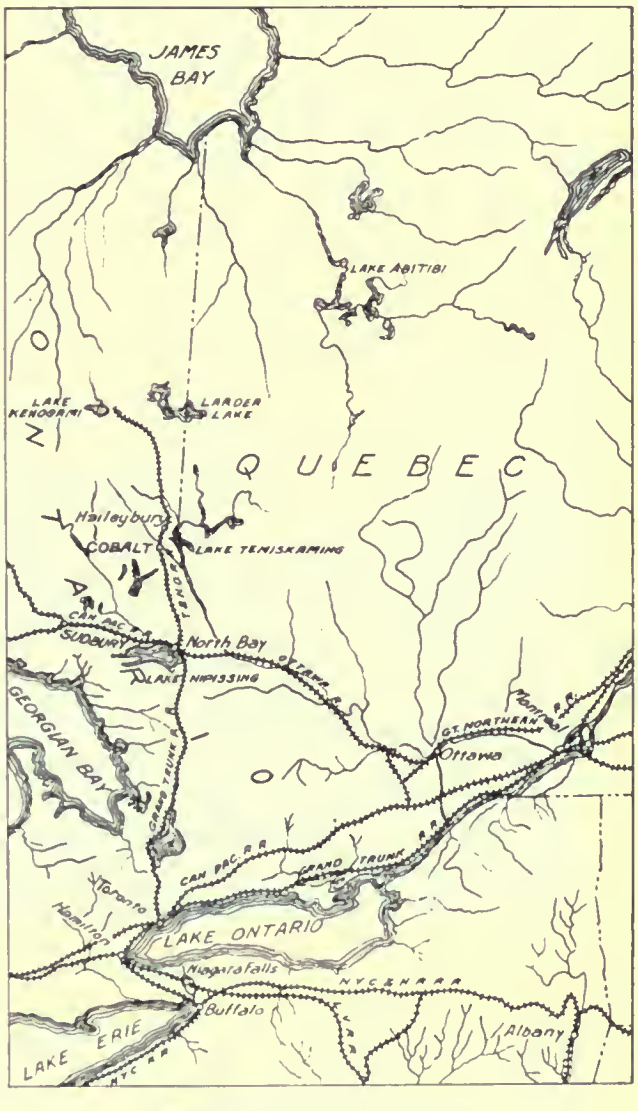
So much attention has been drawn to this new mining district in Canada that the accompanying illustrations are bound to prove interesting. Cobalt was discovered in October, 1903, the first ore having been exposed during the building of the Temiskaming & Northern Ontario Railway, reaching from North Bay on the Canadian Pacific Railway to Haileybury, on Lake Temiskaming. Cobalt is 103 miles north of North Bay, and 980 ft. above sea-level. It is a notable fact that just as the excavations for the railroad laid bare the veins of Cobalt, so also those made for the line of the Canadian Pacific were the cause of the discovery of the nickel deposits at Sudbury, which is 90 miles southwest of Cobalt. The shore of Lake Temiskaming has been an established route to the north for more than two hundred years and it is curious therefore that the rich outcrops at Cobalt—only four miles distant—were overlooked. On the east side of Lake Temiskaming there is a deposit of argentiferous galena that was discovered by *voyageurs* 150 years ago, for it is marked on a map dated 1744. The actual recognition of valuable ore at Cobalt is to be credited to T. W. Gibson, director of the Ontario Bureau of Mines, who was given a sample of niccolite in October, 1903; the man who gave it to him thought it was copper ore. This specimen was sent to W. G. Miller, the Provincial Geologist, and led to an inspection of the district in November. The first authoritative report—by Prof. Miller—was issued in the same month, but no particular interest was aroused until more than a year later, that is, early in 1905. During that year the shipments of ore aggregated 2,144 tons, containing 2,441,421 oz. silver, 118 tons of cobalt, 75 tons of nickel, and 549 tons of arsenic, the total value being $1,468,524. The average value of this ore was $684.94 per ton.

The dominant geological formation consists of metamorphosed fragmental rocks of Lower Huronian age—principally conglomerate, breccia, and slate. The veins occupy nearly vertical planes of fracture that traverse this formation and, to a minor extent, both the older Keewatin schist and a diabase that penetrates the other formations. The workings of all the shipping mines are in the Lower Huronian, but some veins carrying pay-ore have been found lately partly or wholly in the Keewatin. At first it was feared that the deposits would cease when the fractures passed into the underlying formation, that is, that they would be confined to a maximum thickness of 500 ft., but this geological factor is not now so important.

The principal ores are native silver, smaltite (cobalt arsenide), niccolite (nickel arsenide), and mispickel (arsenical pyrite). There are also a number of those beautiful minerals usually found in the oxidized portion of nickel-cobalt lodes, such as the splendidly red erythrite (hydrous cobalt arsenate) and the apple-green annabergite (nickel arsenate). The sulphides of silver (argentite) and of nickel (millerite) also occur, but arsenical minerals are distinctly predominant over sulphides. Antimony, as stibnite, is found; indeed, there is an authenticated story of a carload of ore that was supposed to be worth $15,000 and which on being sampled at New York was found to assay only $8 per ton, because antimonial ore had been mistaken for silver ore. This incident upset a big mining deal and was the cause of a celebrated fiasco.

Native silver occurs generously, in flakes, sheets, wires, and in masses of unusual size. It commonly contains some antimony and occasionally bismuth. The silver antimonide (dyscrasite) is associated with the native silver. Argentite occurs frequently and is easily recognized by its dark color and sectile quality. The predominant matrix is calcite, not quartz; therefore, any seam of calcite is accepted as a leader to be followed in the search for valuable ore.

Mining has led to a partial clearing of the pine forests that formerly covered this region, most of which had previously been denuded of its first growth by the lumbermen. The surface is largely covered with drift, consisting of gravel and boulders from three to six feet thick; even the outcrops of rock are usually clothed with moss, so that prospecting is difficult. Explorations are started by trenching, followed in most cases by an underhand stope that determines whether it is worth while to sink a shaft. The contour of the ground is uneven and hills rise to a



Map Showing Portion of Cobalt.

height of a hundred feet or more. There are many lakes and on the shores of these, natural sections of the formation may occasionally be seen. Calcite is the chief indicator, and the white seams of this mineral serve as a guide to the prospector. Outcrops of ore are not easy to detect; they show native silver (tarnished by oxidation) and cobalt bloom (erythrite), the latter having a pink color that strikes the eye, but it is sometimes mistaken for tints of iron oxide. Argentite has been mistaken for lead, but it is black and can be cut with a knife. Owing to the excessive richness of the ore, even thin veins are worth following and by breaking the adjoining rock other veins have been discovered.

The story of the development of this mining camp is full of picturesque incidents. Immediately south of the Cobalt mining area there was a timber grant held by the Gillies Bros. This 'timber limit' covered one hundred square miles, the extreme northern portion of it extend-

ing to within half a mile of the town of Cobalt; it was known to be rich in silver-cobalt ore. When the local excitement began, this tract was over-run by prospectors who expected it to be thrown open to mining, so that a strong force of constables was required to guard it. In the early part of 1906 the lumbermen who had this timber license began to cut down the pine forest, and it became apparent that when the area had been cleared—in October—there would be an unprecedented rush and many legal complications, because the place of rich mineral outcrops was so well known as to invite a general scramble, with possible violence and even bloodshed. The disposal of the mining rights by public auction was advocated, but in the end the Government avoided the threatened trouble by deciding to work the tract in behalf of the Province, that is, they made it a Government mining property, which is now being operated successfully under the direction of the Provincial Geologist, Mr. Willet G. Miller.

Mining claims are usually rectangular pieces of ground, each covering forty acres, with vertical side and end-lines. Many prospectors had staked claims in winter, when it is practically impossible to make genuine discoveries of mineral, and in such cases the locations were disallowed by the Inspector of Mines. In June the Government obtained a judicial decision, setting aside leases covering 120 acres obtained by false declaration of mineral discovery. Other similar proceedings caused much uneasiness among claim-holders who had secured locations through fraudulent affidavits. The Nipissing Co. was thus threatened in July, but the management was able to satisfy the Government that the company had purchased the ground in good faith without receiving notice of any defect in the title. This episode had a reassuring effect. In November a similar case against the owners of the O'Brien mines (a rich property of 140 acres) was settled, after some litigation, by a compromise, the O'Brien Syndicate getting a clear title upon agreeing to pay the Government a royalty of 25% on the output. This compromise aroused adverse criticism; it indicated the intention of the Government to secure a larger share of the profits from the mines for the people of the Province as against foreign corporations.

In July, the Temiskaming & Northern Ontario Railway Commission, which was authorized to dispose of the mining rights of the Cobalt townsite and the railroad right-of-way (about 60 ft. wide), leased the mining privilege between the 101 and 105 mile-posts to the Right-of-Way Mining Co., which secured a 999-year lease, paying a bonus of $50,000, and agreeing to give royalties ranging on a sliding scale from 10 to 50%. The arrangement created much unfavorable comment, because the terms as advertised had called for a flat rate of 25% and the principal promoter of the company was a son of a member of the Commission. In consequence, the Government canceled the agreement and called for fresh tenders on the basis of a flat royalty of 25%. Only one tender was made, by a syndicate that included three of the original company, and this was accepted. In November and December ore assaying several thousand ounces of silver per ton was taken out of this ground, which is proving to be a valuable mining property.

Silver Queen Mine in Foreground, McKinley-Darragh Behind It; and the Nipissing Near Head of Cobalt Lake.

In November a part of Cobalt lake was drained by the McKinley-Darragh Co., which built a coffer-dam, so as to facilitate the working of veins in the bed of the lake. In December, the Government of Ontario, becoming aware of the value of the lake beds, offered for sale the right to mine under Cobalt and Kerr lakes. The former covers 50 acres, of which four acres had already been sold to the Nipissing company; the latter covers 40 acres, of which 17 had been disposed of. The mining rights to 46 acres of Cobalt lake were actually sold by the Provincial Government for $1,085,000 cash. Kerr lake was not sold, the highest bid being $51,500, which was considered insufficient.

At the beginning of September some extraordinary discoveries in the Nipissing mine added to the fame of the locality, for a new vein that had been uncovered at a place where it was 18 in. wide, was followed on the surface until it opened out to a width of five feet, most of

it being pure silver. This is the now celebrated No. 49 vein. A chunk, weighing 800 lb. and containing 70% silver, was removed at this time, and subsequently it was proved to be part of a mass weighing 3,000 lb. and worth $25,000. These discoveries were due to a novel system of prospecting adopted by the Nipissing Co. In May the management had erected a hydraulic plant on Peterson lake; this was used to wash away the surface soil, so as to lay bare the rock and expose the outcrops of ore. In October there was another phenomenal discovery of a vein 10 in. wide, which was uncovered for a distance of 50 ft. and yielded ore, half of which was silver. In consequence of these rich finds the stock market became excited at this time and quotations on the Curb at New York rose rapidly, culminating in a price, for Nipissing, of $34.50 per share. Many speculative purchases of unproved ground were made by promoters, from $50,000 to $100,000 being paid for claims that had no mineral showing. The capital of the various companies placed on the market reached $200,000,000, a sum wholly out of proportion to the output of the camp. Up to the present time the total shipments of ore are estimated to have been worth $5,250,000.

Referring to the accompanying photographs, that of the Abitibi mine also illustrates the forest of small pines as it appears in early winter. Cobalt lake, ice covered, with the McKinley-Darragh mine-buildings, is shown in another. The largest photograph gives a good idea of the district as it looked a couple of weeks ago, and indicates how the forest is being cleared in the wake of mining operations. The picture of the town shows that Cobalt has grown out of its early uncouthness and is now a compact settlement. It is an orderly place; respect for law is general, by reason of an excellent judicial administration and an efficient police. The town has good hotels, heated by steam and illuminated by acetylene. At present the population fluctuates between 5,000 and 6,000. In winter the thermometer registers between 15 and 40° below zero, but with proper clothing even this is not unpleasant, in the absence of wind.

The future of Cobalt will be solved by actual mining; by its resemblance to the Chalanches mines in France, and by reason of the extreme richness of the ore and the character of the fissuring, one would not venture to predict persistence to great depth, but the facts of mining will always over-ride analogies or theories, and of facts the most encouraging is that La Rose mine has a shaft 300 ft. deep, from the bottom of which a diamond-drill bore was put down 200 ft. further,

The McKinley-Darragh Mine.

in good ore all the way—the last statement requiring confirmation. Nevertheless, it is opportune to point out that in nature the excessive richness of a deposit is not usually characteristic of large and persistent bodies of ore.

Apart from its own production, Cobalt is doing good service to Canada by encouraging exploration in the country northward, west of the line that separates Quebec from Ontario—a region now termed New Ontario. Already finds of mineral have been made near Chibugamoo and Temagami, also on lakes Opastica, Wendigo, and Larder. These have encouraged the building of the railroad into the north country, and they promise to lay the foundations of an important mining industry in a part of the American continent hitherto almost unknown.

The Town of Cobalt, Ontario.

The Abitibi Mine and the Pine Forest.

AFTER the rivers freeze all mail to the interior of Alaska and Nome and St. Michael goes by way of Valdez. From here it is taken by two routes inland, the one reaching Nome and St. Michael via Fairbanks, and the other via Eagle and Tanana. The mail via Fairbanks leaves twice a week, Mondays and Thursdays. Via the Eagle route the mail leaves but once a week from Valdez.

The Mineral Industry of California During 1906.

Written for the MINING AND SCIENTIFIC PRESS
By LEWIS E. AUBURY, State Mineralogist.

During the past year in California a greater amount of development has taken place in the many different mineral products that the State contains than at any time in its history, and all branches of mining have shown a healthy condition.

Gold Mining.—Gold continues to take the lead in the mineral development of the State, and much new territory has been opened during the past year, notably in the desert area—in San Bernardino, Inyo, and Mono counties—bordering upon Nevada. The rich discoveries made in southwestern Nevada are partly responsible for this development, as well as the construction of three new lines of railroad that have given transportation facilities, the lack of which has so long retarded the exploration of the desert region. The mineralized zone that exists on the eastern side of the Nevada line has been found on the California side, and much activity is now apparent in testing the many prospects recently discovered.

In the northern portion of the State hydraulic mining, unaffected by the anti-debris law, continues successfully; a number of new companies have been operating in Siskiyou and Trinity counties. The output of hydraulic mines will probably compare favorably with that of the previous year ($975,000). A number of new gravel mines have been opened, and drifting is now in progress to tap the channels. The output from the drift mines will not exceed that of the previous year, but the work now under way will increase the yield of 1907.

Several new dredging companies entered the field during 1906, and a number of new dredges have been built. New areas are being exploited, particularly in Butte and Yuba counties. From present returns, the various companies operating appear to have had a prosperous year, and the total output of gold exhibits a healthy increase over the previous year ($3,276,145) and it is expected that the platinum saved on the dredges will much exceed that secured in 1905.

Quartz mining has exhibited increased activity in Siskiyou, Shasta, and Trinity counties. This is partly due to the demand for silicious ores at the copper smelters. In Del Norte county a new mining district has been organized and promising prospects are now being worked. Nevada county, as usual, takes the lead in the amount of gold produced. The old mines continue to yield their regular quota of the yellow metal, and the profitable ore continues to the deepest workings. New prospects have been discovered and several old mines have been reopened in Placer, El Dorado, Tuolumne, Mendocino, Calaveras, Madera, Fresno, and Kern counties. Altogether, from the product of the quartz mines of the State, there is reason to believe that we are not losing ground, but that we are continuing to advance. The gold-mining industry in this State is established on a firm foundation. Our mines continue to produce steadily and with the almost total extinction of fraudulent operations, there is an increase of confidence and a constant demand for mining investments.

California's total yield of gold from 1848 to 1907 is far in excess of one billion and a half dollars, and the steady output of the metal, which now approximates over $19,000,000 yearly, gives no indication of diminution.

Copper.—It is my opinion that a much larger production of copper was made in 1906 than in the previous year. The exceptional demand for copper and the high figure at which copper has been quoted for some time past has stimulated prospecting and many properties that had been closed down were reopened and several new finds have been made. Of these the most interesting are the discoveries in the Greenwater district of Inyo county. It is too early to predict the possibilities of this district. Its remoteness from transportation facilities and water have retarded its development, but notwithstanding the many difficulties encountered, very active work is being prosecuted on about 50 different properties. During the next six months, exploratory work will have probably progressed sufficiently to determine the persistence of the ore deposits. Promising prospects are also being opened up in Siskiyou county, and it is probable that the copper belt of Shasta county will be found to extend through Siskiyou and even to the Oregon line. Shasta county, however, still continues to lead in amount and value of copper product. During the past year, the Mammoth smelter at Kennet was blown in and has been running steadily. A railroad has been planned to connect the Bully Hill and Great Western smelters with the Southern Pacific railroad, and if constructed, the delays heretofore existing in the transportation of coke, will be overcome, and a more steady production assured. The Mountain Copper Co. has been shipping most of its ore to the works at Martinez, but may resume operations at Keswick in the coming year. In Calaveras, Placer, Fresno, Mariposa, and Nevada counties, much active work has been prosecuted and all of the above counties will probably show an increased production.

Quicksilver.—California furnished the bulk of the quicksilver produced in the United States in 1906. No unusual demand was made for this mineral during the past year. On this account no particular activity was displayed in developing any new territory, the chief developments being confined to San Luis Obispo, Santa Clara, Lake, Napa, and Sonoma counties.

Borax.—One of our important industries, and one which is constantly growing, the product being obtained from San Bernardino county, is borax. Most of it in recent years has been obtained from near Daggett, but, owing to the great demand, it has been found necessary to re-open the deposits of Death Valley, in Inyo county, and in order to obtain better transportation facilities, a railroad is now in course of construction to that point from Ludlow. This road will also tap the nitre deposits, as well as an undeveloped region abounding in great mineral possibilities.

Soda.—All of the soda so far produced in California has been obtained from Owens lake, in Inyo county. Although large surface deposits have been found in San Bernardino, Riverside, and Kern counties, they have not as yet been worked. California contains practically inexhaustible quantities of soda, both in the carbonate and sulphate form. The soda deposits only await the touch of capital to transform them into profitable producers. Yet, with an abundance of raw material in our State, we annually import from Michigan and New York many hundred thousand dollars' worth of soda products. Working chemical tests have been made on the desert soda, and from them it has been demonstrated that a product can be obtained fully equal to that of the imported article. The amount of crude soda produced last year will probably exceed 15,000 tons.

Structural Materials.—The advancement which has been made in the exploitation of structural and industrial materials may be particularly mentioned, and a marked increase in the amount and value of these substances will probably be noted when the official statistics have been completed.

The calamity that befell San Francisco in April last is largely responsible for this development, as the necessity for an immediate supply of the different classes of material employed in the reconstruction of San Francisco

caused investors from all over the United States to investigate the possibilities of securing in California the raw materials for the manufacture of cement, terra cotta, tiling, pressed and glazed brick, and other clay products; also, marble, sandstone, and granite for building purposes. The majority of the clay deposits and quarries already opened being called upon to supply the unusual demand, they have been actively worked with increased forces.

The three cement plants—at Cement, Vallejo Junction and Colton—have had more than they could attend to in supplying material for home consumption. Another large cement plant has been established near Santa Cruz, and others are contemplated.

Gypsum has also been in great demand, chiefly for the manufacture of plaster of paris. A large amount of this material has in the past been imported from other States, but during the past year many deposits have been opened in this State. Some of the largest deposits of gypsum in America, and of the finest quality, have been found in southern California, but on account of distance from railroad transportation, it has not been found profitable to exploit them.

California builders are beginning to appreciate the qualities of slate, particularly for roofing purposes, as its superiority in the Coast climate, and its fire-proof qualities over other material commonly used, appeal strongly in its favor. The greater part of the slate produced came from El Dorado county, although work has been prosecuted in several new quarries.

The glass industry offers exceptional opportunities for profitable investment in California, as most of the plate and window glass used in this State is imported from Indiana and Pennsylvania. Several bottle-glass manufactories are in operation, and the output of these plants will doubtless show a marked increase in production for 1906.

Magnesite mining has also shown a decided advancement during the past year, and the demand for this material is largely increasing. Up to 1906, its principal uses in this State were for the manufacture of carbonic acid gas, the residue being shipped to the paper mills. During the past year, plants have been constructed for the manufacture of magnesite bricks, tiling, and plaster compounds. Magnesite was mined principally in Tulare, Alameda, and Stanislaus counties, although existing in several other counties of the State.

Rubble for road work (macadam) and for concrete has shown a large increase in the amount of production for 1906. The 'good roads' movement throughout the State is partly responsible for this increase. The large amount of concrete construction both in northern and southern California has also added to the consumption.

Other Industrial Minerals.—Besides the minerals already enumerated considerable prospecting has been done during the past year for asbestos, mica, pyrites, tungsten, and talc, all of which will probably show some increase of production over that of 1905.

All of the industrial minerals without exception appear to have attracted more interest than formerly. A renewed demand for antimony, chromite, bismuth, mineral paint, lead, and manganese has been apparent during the past few months, and many inquiries have been made at the State Mining Bureau for feldspar (to be used for glazing pottery) and for clay products generally. Special interest has also been directed toward high-grade clays from which porcelain and china ware can be manufactured. California annually imports thousands of dollars worth of this ware, and as the finest qualities of clay suitable for the purpose are obtainable here, it is probable that in the near future manufactories will be established.

At San Diego a movement is on foot to erect a chemical plant for the manufacture of lithia compounds. A large amount of this substance has been developed near Pala in San Diego county, and for years past the product has been shipped to Germany for chemical treatment.

Petroleum.—For a number of years this product has shown an increasing output, and this increase will be marked in the statistics for 1906. A greater demand was created during the closing months of the year than at any previous time. This was doubtless due to the large contracts entered into with Japan, and the completion of the pipe-line across the Isthmus of Panama, through which petroleum will be piped and supplied to the Atlantic Coast. Shipments are now being made to the Pacific terminal. The outlook for better prices is evident in the exceptional demand. A large amount of new territory is being prospected, and many new wells

California.—Showing Position of the Counties.

are being sunk in the proved districts. Owing to the low prices that formerly prevailed, and also to overproduction, comparatively little prospecting had been done for some time, and many strong producing wells were capped, but now all of this is changed, and every effort is being put forth to supply the present demand.

The superiority of California asphalt has created a demand for it outside the State. Most of the asphalt is obtained as a by-product in the refining of petroleum. One of the principal uses to which it has been applied has been in street pavements and roofing, although in the near future it will doubtless enter largely into the manufacture of new fuels. The demand for asphalt has been greater than ever before, and the supply has barely met the demand. The requirements for the coming year will undoubtedly require the re-opening of several bituminous rock deposits in southern California that of late years have been closed. The output of asphalt will unquestionably exceed that for the previous year.

Fuel.—Since the development of the petroleum industry, the mining of coal in California has not been active, and the greater economy in the use of petroleum for steam-making purposes has been the cause of many coal mines closing down or decreasing their output. However, owing to the advance in the price of petroleum

during the past two months, and the exceptional demand for coal for domestic purposes, the output of coal mines has been increased lately.

Iron.—California has long been known to possess large deposits of iron ore and of a character that will compare favorably with the Michigan ores, but the iron deposits of California have attracted comparatively little attentiou on account of the fuel problem. Owing to the high cost of a suitable coke, it has been found unprofitable to smelt iron ores in this State and compete with the Eastern market. To overcome this difficulty many useless attempts have been made to smelt iron ores with California petroleum—without regard to metallurgical laws.

A plant is now in course of construction in Shasta county for the reduction of iron ores by electricity, using the Heroult process. Experiments on a small scale with this method have proved successful during the past year in Canada, but granting that it will prove a metallurgical success on a large scale, it remains to be seen if it can be made a commercial success, when the cost of electrical power is taken into consideration.

The reduction of iron ores in this State has been given grave consideration for some time past by some of the most able metallurgists in both the United States and Europe, the question has been considered in all its phases and experiments are continually being made to solve a problem which means much for the industrial advancement of the Pacific Coast.

Experiments are now being conducted in the manufacture of an artificial coke. California coal (lignite) enters largely into its composition, combined with petroleum and other products. The difficulty of utilizing a lignite that contains a large percentage of ash appears to have been overcome by grinding and washing previous to its incorporation with the other ingredients. Small lots of the manufactured coke appear to have the necessary qualities, as to strength and fuel properties, but only demonstration on a large scale will prove its efficiency.

California peat has also received increased attention, and large areas of peat-bearing lands have been purchased with a view to supplying a demand for domestic fuel. Many schemes are now on foot whereby peat will be used both in a compressed form and in conjunction with petroleum. One factory is about completed on the bay shore in which peat-petroleum and briquettes will be made. Preliminary tests of the new fuel have demonstrated its value both for domestic and steam-making purposes. In southern California it is proposed to erect a plant for the manufacture of compressed peat-blocks for fuel purposes.

Gems.—The gem industry of California continues to grow, particularly in San Diego, Riverside, San Bernardino, and Tulare counties. The output of tourmaline, kuntzite, beryl, topaz, aquamarine, turquoise, garnet, and other gem-stones continues to be greater yearly, and operations formerly of small consequence are now developing into an important industry. Outside of the product of the gems above mentioned, companies have been organized during the past year to mine for diamonds in Butte and Amador counties. The gem product of 1906 will exceed that for 1905 ($148,500).

Official figures of production are not compiled before June of each year by the State Mining Bureau, hence it is impossible to furnish accurate statistics of production at this time.

EVERY true scientific discovery is the result of a natural process of development, which leads, through more or less numerous errors and misconceptions, to a definite and lasting result.

The Copper of Shasta County, California.

I.—Geology.

Written for the MINING AND SCIENTIFIC PRESS
By DONALD F. CAMPBELL.

The copper region of Shasta county is about 30 miles long and a few miles wide; it may be compared to a crescent with Iron Mountain at the western end and the After Thought mine at the eastern extremity. While the whole area is mineralized, the productive districts are limited to two smaller zones, each having characteristics of its own. At the western extremity are the large masses of heavy sulphide, which must first be considered in detail. This district includes the Iron Mountain, Balakalala, Trinity, and Mammoth mines, and a number of prospects from which important developments may be expected in the future. These deposits occur almost entirely in acid volcanic rocks, notably a rhyolite made up of a succession of irregular flows and tuffs that have been so compressed and folded as to render obscure the original character of the mass. When fresh the rock is gray, generally with distinct phenocrysts of quartz, and in the neighborhood of zones of mineralization it is highly impregnated with pyrite or an iron stain. Flow structure may be noted and the effect of quick cooling, which finds expression in a hexagonal structure, while brecciation and tuffaceous masses are common and especially noteworthy on the summit of Iron Mountain.

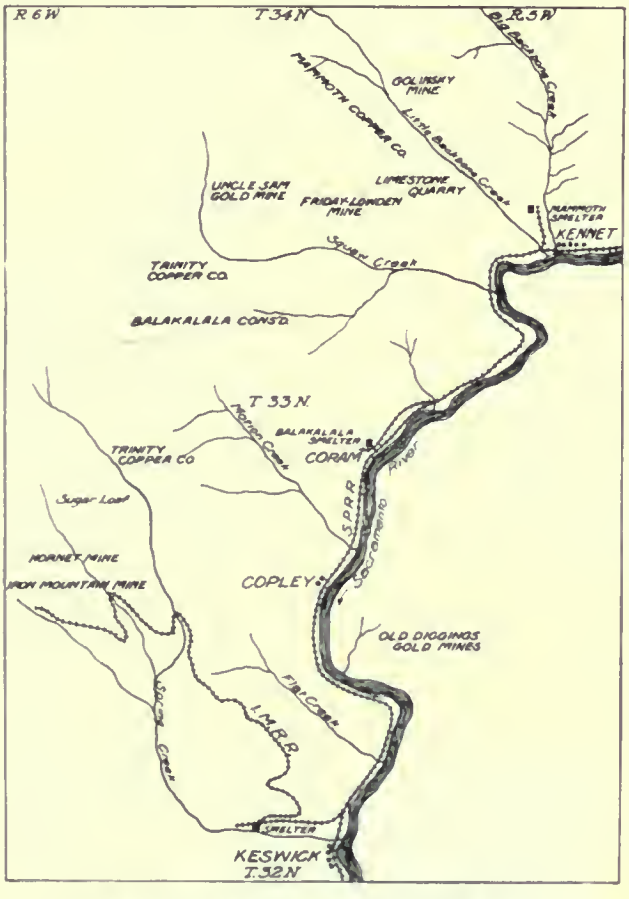
The petrographic structure of the rock is simple, though, in the field, it is apt to prove deceptive. At one place, the large phenocrysts of quartz will be found several millimetres in diameter, while quite near will be found an apparently granular specimen of a uniform gray color. This lack of porphyritic structure is often more apparent than real because, by careful investigation, the phenocrysts of quartz are plainly visible.

The rhyolite occurs in many phases, sometimes assuming a dark green color owing to alteration and at times grading into a meta-rhyolite.* On the west, the rhyolite is bounded by shales and conglomerate of Devonian age, but its age relative to the sedimentaries is not easy to determine. These have not been productive of copper. There is, however, one occurrence of sulphide ore carrying copper and precious metals, exposed in the Lone Star mine, a slightly developed prospect, which is of interest as being the only contact deposit in this district. In this case, the copper deposits seem to be limited to the rhyolite.

The principal deposits of the district lie on well-marked lines of shearing and mineralization. These are numerous, but no definite relation can be traced between them, though individual zones may extend for a mile or more. Iron Mountain may be considered in detail as being typical of the ore deposits of the district and because it has been so thoroughly explored. In the course of mining, miles of adits have been driven and over nine miles of diamond-drill holes have been bored. Mineralization has taken place very generally within a wide zone that has been subjected to great shearing and fissuring. This is readily seen by the brown stains and casts from decomposed pyrite and the secondary silicification, which produces the bluffs and jutting crags that characterize these mineral belts. This secondary silicification is a matter of the utmost importance, because the pres-

*A microscopic examination of the rhyolites of Iron Mountain indicates that they are all closely related, though differing widely in the degree of alteration. Silicification is very marked, and, in extreme cases, the rock has the aspect of a quartzite remarkably like some sedimentaries. In this rock, there are traces of mica that show faintly the structure of the rhyolite, and some crystals of pyrite are sprinkled through the mass. Phenocrysts of quartz may be absent in this phase, but in almost all others they are well marked. Dark green varieties of these rocks occur and have been mistaken for basic rocks, but they are merely a phase in which considerable quantities of chlorite surround the quartz phenocrysts. Many specimens exhibit the effect of shearing and fissuring, and present schistose structure with sericite.

ence of veinlets of silica, or an increase in the percentage of silica is often an indication that an orebody or, at least, an impregnation of sulphides is near. Silica determinations in drifts approaching orebodies will corroborate this, while the excess silica may often be seen occurring as veins of quartz near the ore. Economically, the ore-



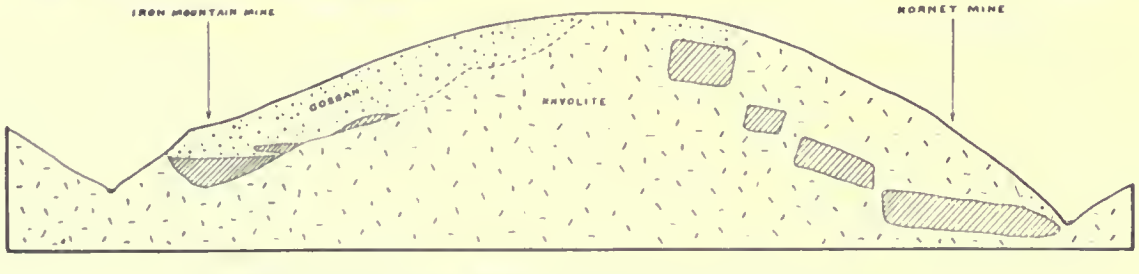
Map of a Part of Shasta County, California.

bodies themselves may be considered to be of two types, though geologically they are identical. There are the high-grade or 'basin' deposits, such as that of Iron Mountain, and the low-grade masses such as that of the Hornet mine. The only difference is that the former exhibit secondary enrichment, while the latter do not.

The Iron Mountain orebody is shaped roughly like a ship heading northeast with overhanging bow and stern and a round bottom. Its sides are bounded by two great fissures, within which the whole mass of rock, about 600 ft. long and 300 ft. wide, has been replaced by sulphides. These two fissures converge in depth and the east wall cuts off westward, forming the keel of the ship. The upper levels have been entirely oxidized, but the precious metals have remained, while the copper has sunk and enriched the sulphide zone, the secondary enrichment decreasing in depth.

The ore shows this in the bands of chalcocite and chalcopyrite, which, with covellite, may be traced in the ore of the upper levels. Assays also exhibit a slightly decreasing percentage of copper as depth is attained. It is interesting to note that the sulphide zone has a very well-marked and horizontal top, although the mass is situated on a steep hill, suggesting that the oxidation must have taken place long ago before the topography had obtained its present form. That these are merely due to the replacement of great masses of country rock is proved by the presence of crystalline quartz-phenocrysts from the rhyolite, which are found in the silica residues on dissolving the ore. In the massive croppings numerous phenocrysts may be seen and all stages of replacement observed, and, in the sulphide ore, the fissure system of the rhyolite may sometimes be traced. Further evidence is found in the unaltered porphyry filling occurring in certain fissures in the pyrite masses, which have apparently withstood impregnation owing to their impermeability. Why certain masses of rock have been so utterly pyritized, while others show little or no alteration, is unaccountable.

In tunneling into these bodies, one passes from a barren silicified rhyolite to a thick clay gouge behind which is a smooth and undulating wall of heavy sulphides. There is little or no warning until the wall is reached. The bottom is the same; in fact, the wall merely flattens out. It will be natural to wonder what becomes of these great fissures in depth and whether there are any productive veins that acted as feeders to these lenses. It is noteworthy that no mining has been done below the gulches and no shaft has been sunk in the district; in fact, the only orebody that has been thoroughly explored in depth is that of Iron Mountain. But these investigations did



Geological Section of Iron Mountain, Showing Position of Sulphide Orebodies.

This can readily be seen in the geological section. To the west there are the great lenses of Iron Mountain covered by an iron hat, from which the copper has all been leached and deposited in the 'basin'; to the east, the Hornet orebody is in its unaltered condition, with little or no gossan, and consequent slight enrichment. The prospects of finding high-grade deposits in this part of the county without an extensive cap of gossan are not good, though this is not the case in the Bully Hill district. The character of these sulphides is similar to that of Rio Tinto, though the occurrence is somewhat different, for the former occur as shallow basins surrounded by rhyolite, and the latter go to unknown depths associated with porphyry and slate.

not lead to any discoveries of importance. That a few narrow zones impregnated with copper and iron occur throughout the mountain may be said to be all the encouragement that the diamond-drills could give, and hence it is improbable that deep mining will be carried on.

At Iron Mountain the orebody itself has not escaped dynamic disturbance, the major line of thrust causing a fault across the middle of the mass, by which the northern end is thrown upward about 60 ft. in a fault-plane having a dip of 70°. This may readily be seen by the clean polished surface on the fault and by the character of the ore on both sides of it. Specimens taken on the same level on either side of the fault differ in appearance and

in their contents of copper, proving that most of the secondary enrichment was prior to this faulting. There are two other families of fissure planes of less importance, which have a bearing on the economic mining of the ore, though they have no marked bearing on the geology of the mass. The Iron Mountain orebody has 6% copper, $1 in gold, about 1½ oz. silver, and 48% sulphur.

The other orebodies are not dissimilar in character, though they have less gossan, and all carry less copper. The Sugar Loaf hill, lying between Iron Mountain and Balakalala, has been prospected for many years with little success as yet, though it is probable that orebodies will be found on the northeast slope.

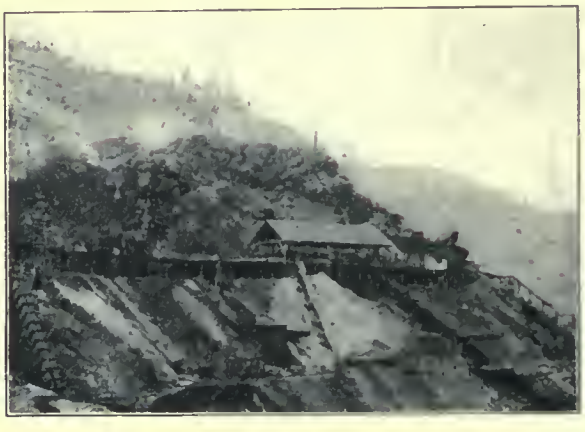
On walking down the steep gulch of Spring creek, full of boulders from the Devonian sedimentaries at its head, the productive rhyolites again form a barrier beyond which the younger camps of Balakalala and Shasta King

Secondary Silicification of the Mineralized and Sheared Zone That Contains the Orebodies of Iron Mountain.

come into sight with the broad expanse of the Stillwater plains beyond.

The landscape changes here from the barren hills of Iron Mountain, sparsely covered with manzanita and scrub or poison oak, to a well-timbered country traversed by steep gulches, under frowning bluffs. Far away at the foot of the bluffs is situated the Shasta King camp, owned by the Trinity Copper Co., while beyond Squaw creek is the Mammoth, which has recently proved itself to be the largest orebody yet discovered. About half way down the mountain, overlooking the Sacramento river, the Balakalala mine is being developed and is proving to be one of the great low-grade mines of the belt. The ore, however, differs from that of Iron Mountain or the Mammoth in containing a higher percentage of silica. The form of the orebody is as yet not fully determined. Within a mile, the Windy Camp group of claims are likely to develop into a valuable mine, in consequence of the vigorous exploration now under way. The Balakalala lode is one of the most prominent in the district. It is heavily capped with gossan and can be traced for more than half a mile. The Windy Camp orebody is possibly on the same lode and has been traced about 1,000 ft. on its strike. The orebodies here are variable in width and the replacement of the country rock has not been complete. Just below Windy Camp are the Shasta King workings. These have outlined an irregular basin several hundred feet wide, united by zones of shearing and fissuring in which there are deposits of sulphide ore of fair grade. The Mammoth mine has certain peculiarities, which have been exposed by recent developments. The ore was followed down and apparently the bottom of a basin reached. It was soon found, however, that the orebody was not merely a shallow basin, but that it extended up the hill as a hook-shaped mass, the shank of which lay sloping up the hill and the point of which was at the outcrop.

The geology of the Bully Hill district is very different and more complex. A series of volcanic rocks, both acidic and basic, form Bully Hill. This is traversed by a number of irregular lines of shearing and mineralization. In these, orebodies occur irregularly distributed in masses of varying extent and richness. The deposits, though smaller and more irregular, often contain more copper and precious metals than those in the western part of the district. Zinc blende, barite, and chalcopyrite are important constituents of the ore in this and the After Thought districts. The development of the old Copper City district and the Winthrop mine is being taken up by the Bully Hill company, and good orebodies are being opened up. Small deposits of oxidized copper ore have been found in the limestone surrounding this district, but hitherto they have not received much attention



Outcrop on Iron Mountain. Steam Issuing From Mine Fire.

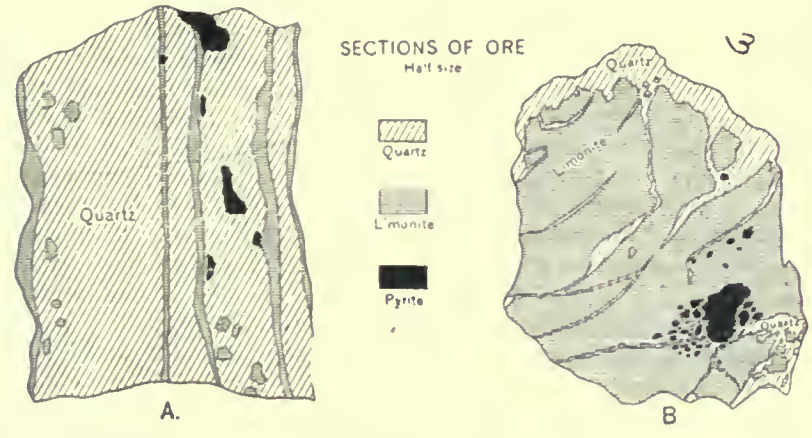
owing to their rough and inaccessible surroundings. The Afterthought mine has an ore that contains large quantities of zinc and barite, which make the ore refractory to smelting. It is possible, however, that these zinky ores may become profitable as a source of that metal. The iron ore deposits at the junction of the McCloud and Pit rivers afford another field for investigation. This district holds out some promise of copper discovery, but the traces of sulphides and pseudomorphs suggest that a pyrrhotite or pentlandite, similar to that of the Sudbury district, may have been the original source of these interesting deposits.

By following the scientific disputes of the past (and indeed no period has been free from these disputes), a kind of personal acquaintance with the character and manner of thought of the writers is involuntarily obtained, along with a practical experience of the problems of science. Two additions to the knowledge of the individual writer are thus obtained. The reader acquires a lively sense of scientific and of personal style; at times he is annoyed by the prolixity and vagueness of one writer, or pleased by the concise clearness of another, and endeavors to attain in his own works that which has been so pleasing in the works of others.

Secondary Changes at Cherry Creek, Arizona.

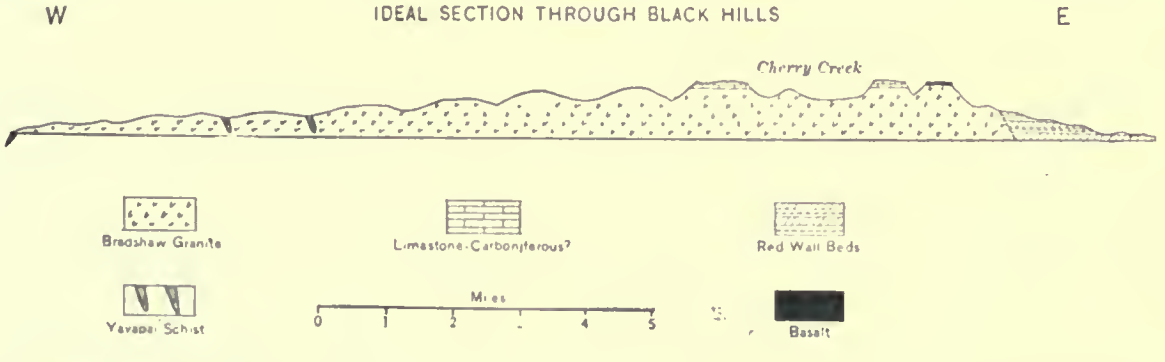
By JOHN A. REID.

*The phenomenon of secondary deposition of minerals in the Cherry Creek district is peculiar and interesting, both from a mining and from a scientific standpoint. The development work in the mines has not yet progressed far enough to exhibit all the changes which have occurred, yet there can be no doubt that the four zones of Emmons[1] are almost ideally developed. Furthermore, the veins already opened show the instability of any one set of geological conditions, for the zone of impoverishment is invading the zone of rich oxides, which in turn is encroaching upon the rich sulphides below. The causes operating to make possible these continued changes are easily found. At least three distinct sets of movements fracturing the vein filling and enclosing dikes have occurred, so that the vadose waters have been free to circulate. The present water-level in the mines is strikingly different from what it must have been in times past, for permanent water is found at about sixty feet, or even less in some mines, below the surface, while the heavy oxidized ore continues downward to unknown depths. A recent wet year is largely responsible for present conditions, but not entirely, for before the rains of 1904–5 the mines were water-bearing in some degree.



The zone of impoverishment, because of the continued leaching it is undergoing, presents several interesting features. As discussed by Emmons,[2] Weed,[3] and others, this surface zone is characterized by low values or lack of values, containing usually nothing but oxides of iron and silica. In Cherry Creek, however, a subzone of further impoverishment exists, from which not only the values have been leached, but also the iron oxides and even silica have been partially or very largely removed. The two factors of age and openness of veins have been chiefly responsible for this. At the surface, quartz, in most veins, outcrops in stringers and larger masses. Such surface quartz is not often prominent, because of the shattering of the material, although hard boulder-like fragments occur, surrounded by softer rock. In a few veins the outcrop is prominent, and is composed of quartz stringers in granite porphyry, the hard mineral restraining the erosion of the whole. Limonite, in stringers and veinlets, cements this broken quartz. The iron oxide frequently appears as pseudomorphs after pyrite, the form of the pyritohedron being very common. The main direction of breaking is parallel to the plane of the veins, hence the larger veinlets of limonite are more or less parallel, giving a rough effect of ribbon structure (see A in Fig. 2). Below the outcrop a few feet the quartz and contained limonite decrease in abundance, frequently disappearing entirely. Assay values showed the same, returns from the surface being notably higher in the majority of cases than five or ten feet lower down. Furthermore, in the instances where the quartz has only partly gone, the iron oxide has almost entirely been carried below, taking with it the gold values. In one of the larger east-west veins, the upper seventy-five feet has been thus leached of all but a trace, while below that depth good ore exists in quantity.

After the barren, or nearly barren, portion of the veins has been passed through, heavy rich limonite in quartz is encountered. The aphanitic texture is always prominent, and small shiny areas of unaltered pyrite are frequently present in the midst of the heaviest iron oxide (see B in Fig. 2). Secondary quartz, at times jaspery, is noticeable in this portion of the veins, and occurs both in irregular patches and in small veinlets in the limonite. The heavier the oxide, the larger the amount of secondary silica. At the Golden Idol mine, in which the vein material is about 90% iron oxide, the limonite extends to the surface. The outcrop is eighteen inches wide, assaying a low value; forty feet down the vein is five feet wide, of almost solid rich limonite, with a very rich ten-inch streak in the centre. The centre streak is well defined and clearly a deposit later than the enclosing material. In the bottom of the workings rich sulphide ore is commencing to show, below the present water-level. In the phenomenon of the veins being narrowest at, or just below, the outcrop, it is to be noted that the walls in the narrowest portions show evidence of lateral pressure and crushing, attendant upon the removal of material from between them.



At present writing the zone of secondary sulphides has been merely touched, only residual fragments of these minerals having been extracted. Their occurrence, however, demonstrates two facts: First, the actual presence of a zone of secondary sulphide enrichment; and, second, the gradual migration of this zone downward. The sulphides found are extremely heavy, and constitute

*Abstract of paper entitled 'Sketch of the Geology and Ore Deposits of the Cherry Creek District, Arizona,' by John A. Reid. *Economic Geology*. Vol. I, No. 5.

[2] S. F. Emmons, *Trans.* A. I. M. E., Feb., 1900, pp. 463–461.

[3] W. H. Weed, 'Enrichment of Silver Veins,' *Trans.* A. I. M. E., Feb., 1900, p. 476.

some of the very richest ore. In the western veins, copper sulphides have been found only in small amount; on the eastern slope, chalcopyrite and bornite are found in increasing amount with depth. Not the most minute traces of oxidized copper minerals have been seen in any part of the district. At the Pfau mine, situated in the large dike on the east slope of the Black Hills the ore is apparently very thoroughly oxidized, yet a search in material from the lower levels will be rewarded by lumps of copper iron sulphides, often eight inches in diameter, covered with a half inch shell of earthy limonite. Chalcopyrite is in larger amount than the bornite. Pyrite occurs in the higher portions, just as in the western veins.

The peculiarity, then, of the secondary deposition of minerals is evident. The zone of oxide enrichment contains limonite and quartz, with free gold, and no traces of copper. The small amounts of sulphides and pyrite toward the surface, changing into copper minerals below, these latter minerals being best developed in the eastern veins. Further, the double sulphides of iron and copper are found exclusively, no chalcocite or covellite being present. What may be below is extremely problematical, but it would not be surprising if the simple sulphides are there in abundance. It is worthy of note in this connection that the United Verde mine at Jerome was worked solely as a gold mine in the early stages of its history, and had a precarious existence until the rich copper ores were struck in depth.

In the typical copper vein the oxidized zones contain copper minerals, often in great abundance, and outcropping on the surface, as at Globe, Bisbee, and Clifton, in southern Arizona. At Cherry Creek and Jerome, such oxidized copper ores are conspicuously absent, while the surface zone is wholly or partly leached, not only of its values, but also of its gangue. The conditions causing such a result are of two kinds: Structural and chemical. The structural conditions are those of movements in the veins, shattering the country rock as well as the vein stone, thereby opening well the ores to surface agencies. The chemical conditions are, in their nature, more obscure, and can only be surmised at this writing. Azurite, malachite, cuprite, and crysocolla, are stable under the common conditions found in the oxidized zones in copper veins, so that their complete absence proves the existence of a situation chemically somewhat unusual. Also, the peculiar effects noted in the veins at and just below the surface call for explanation. The most notable characteristics of the veins are: (1) The abundance of limonite; and (2) the prevalence of a gneissic or schistose structure accompanying the veins and the bleaching of the rocks by the action of sulphuric acid. At times the action of the acid has proceeded sufficiently far to produce from the rock a white pulverulent mass. This intense action is always found in the very summits of the veins just below the outcrop.

The first striking feature, the quartz outcrop followed below by a vein filling poor in constituents of foreign source, can be easily explained. The active solutions start from the surface, enter the vein, and because their power is least at the start, and because fresh oxygen-bearing water follows, the actual outcrop is comparatively little attacked. On the other hand, the solutions passing through the first foot or two of surface vein filling, and taking up the acid found therein, are held in contact for some time with that portion and their leaching action becomes intense. The deposition of the material thus taken into solution necessarily follows as the waters percolate downward.

Secondly, with an abundance of iron and sulphuric acid, and with the free access of oxygen, the secondary copper minerals, so commonly found in the upper portions of veins, could not form. The cupric sulphate, produced both by the free acid and the ferric sulphate, would be carried down to the bottom of the zone of oxidation. Under these conditions the gold would also be leached from the surface and deposited on the oxidation of the iron salts to hydrate. Silica would also be deposited as the character of the solutions change. Rickard,[1] in his valuable paper, has presented the main facts regarding the enrichment of gold veins, although he leaves rather in abeyance the fact that sometimes gold migrates and at other times it does not. The migration in the Cherry Creek district is no doubt chiefly caused by the very large amounts of ferric sulphate present, aided possibly by chlorides from the overlying limestone. It is not clear exactly what solvents are responsible for the downward movement of the silica. That silica does so move is well known; witness the frequent sintery quartz of vein outcrops. Also, at the Comstock lode, the vadose waters, containing 11% of soluble sulphates and 12½% of free sulphuric acid, hold in solution 0.55% of silica. Simple equations expressing graphically the relations outlined above, could be written, but it seems inadvisable to do so until our precise knowledge is greater.

A further point is this: Among secondary sulphides present, those bearing copper are invariably the double salts of copper and iron, with chalcopyrite in larger amount. The reasons for this may also lie in the excess of iron and sulphuric acid present in the vein. The presence of sulphuric acid necessitates a plentiful supply of oxygen, which is not at all at variance with the facts of vein shattering. If equations be written expressing the probable reactions producing the minerals chalcopyrite, bornite, and chalcocite, or better, general equations summing up all intermediate reactions, it will be found that, in the main, chalcocite will form when the ratio of the copper to the iron is as 2:1; bornite when this ratio is 3:2, or, when both iron and a strong agent are in excess, 3:1 chalropyrite when this ratio is 2:3, or, when a strong reducing agent is present, 1:1. As the veins have been well opened to oxidizing solutions, in the upper portions of the veins strong reducing agents were lacking. In this case, the ratios of copper to iron for chalcocite, bornite, and chalcopyrite are 2:1, 3:2, and 2:3, respectively. Thus, the excess of ferric salts and lack of strong reducing agents would favor the formation of double sulphides. It is needless to state that the whole subject of the physical chemistry of this comparatively simple process of secondary enrichment of copper ores, is in need of thorough experimental treatment before we shall be in a position rightly to interpret the facts. The working geologist lacks time and often the requisite knowledge for pursuing such investigation, and must, perforce, depend upon the labors of others. At Cherry Creek, however, the facts in the field, such as the great abundance of limonite with frequent kernels of pyrite the vein shattering, and the bleaching action of sulphuric acid, appear to warrant the tentative conclusion above set forth.

With depth, it is almost beyond doubt that the gold values will decrease while the copper will increase in amount. At what depth a pronounced change will be found it is not possible to say. The deepest mine workings show ore thoroughly oxidized, with the exception of a few residual sulphide masses, and practically of the same chemical nature throughout. The ground water now being well above the bottom of the zone of oxide enrichment offers no criterion, but proves only the existence of a more arid past. The gold values will continue through the zone of oxidation and into the underlying

[1] T. A. Rickard, "The Formation of Bonanzas in the Upper Portions of Gold Veins," *Trans.* A.I.M.E., Feb., 1901.

zone of secondary sulphides, and there should be considerable depth to the gold-bearing minerals. If the above ideas regarding the genesis of the double sulphides be correct, it is possible that chalcosite may be found with greater depth, formed after much of the iron has been left behind as limonite. In any case, there should be an abundant supply of good ore, both with gold value and with copper as the chief metal.

Estimate of Supplies Needed to Run a 10-Stamp Mill for One Month.

(1) 10 gal. engine-oil. Lubricants of all kinds are generally wasted by ignorant or careless employees so that a liberal quantity is here provided.

(2) 10 gal. cylinder-oil. With care and the use of sight-feed lubricators, a much less quantity should do.

(3) 50 gal. coal-oil for lighting. This will vary with the season, the latitude, and the number of lanterns used.

(4) 25 lb. soft cup-grease. For rock-breaker and for the shaft bearings.

(5) 6 one-pound boxes of axle grease. For cams. When properly applied it gives a coating which thereafter needs but a touch of grease.

(6) 1 box of candles. About 6 candles will be consumed per night. This item may be omitted where incandescent electric lights have been properly installed.

(7) 50 lb. cotton waste. After this has been used by the engineer, it should be washed and used for wiping the shafting and the rock-breaker.

(8) 10 lb. assorted packing for engine, valves, etc. The kind of packing will depend on the engine, and should be enough to repack stuffing boxes and valves monthly.

(9) 1 sq. yd. of 1/16-in. sheet rubber. This is needed for gaskets for screens and joints.

(10) A half-pint each of sulphuric and nitric acid. This is useful to dissolve out cast iron, copper, etc., from the residuum at a clean-up where the gold or amalgam is cleaned from impurities.

(11) Five pounds each of potassium cyanide and of concentrated lye. Cyanide of potassium is useful when coating the plates with mercury, or to clean them when they become discolored from arsenic, sulphur, etc., in the ore. The concentrated lye is useful to remove grease from the plates where it has, through any carelessness, gotten on them.

(12) One ounce of metallic sodium. This is used for cleaning the mercury after retorting.

(13) Four ounces of prepared amalgam. To use on the plates at first starting a mill; if this runs continuously it is not again needed.

(14) Three flasks mercury (75 lb. per flask). For amalgamating the plates and feeding to the batteries.

(15) Half a dozen whisk brooms. For brushing the plates. These brooms should be cut to half their usual length so as to give a good stiff brush.

(16) One fine sponge. (For taking sand, etc., from the surface of amalgam or mercury).

(17) One yard of 8 oz. cotton duck. For straining the amalgam.

(18) Two putty knives. For use on the plates for scraping up the amalgam.

(19) One Wedgewood mortar and pestle 10 in. diam. For grinding small lots of amalgam.

The approximate cost of above supplies is $250.

CAPITAL competes with capital, labor with labor; but capital cannot compete with labor any more than labor can compete with capital. Competition can only exist between factors of the same order.

Overfire in Copper-Matting Blast-Furnace Smelting Practice.

Written for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

Anyone accustomed to the quiet running of a silver-lead blast-furnace, with its reducing atmosphere and its cool top, is worried by the way a copper blast-furnace is operated, with its abundant overfire, pyrotechnic shooting up of pieces of ore, oxidizing blast effects, and highly heated escaping gases often (just before putting in a fresh charge) of the temperature of 900° F. (485° C.) He knows that for the best and most economical running of his furnace, it should have the proverbial cold head and warm feet of the healthy man; that is, the surfaces of the charge should be cool, having no visible heat or flame coming up through it, and there should be the intensest combustion of the fuel at the tuyeres, since one thus obtains a hot well-melted slag, with fusion and reduction well completed.

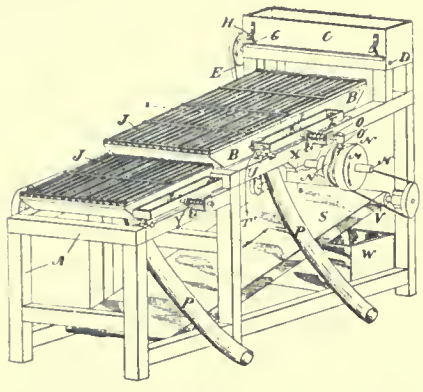
For all this we find, even in the case of those metallurgists who have been accustomed to silver-lead practice, that they are willing to submit to abundant overfire in their copper blast-furnaces under plea that they get (as they do) good results from so doing. Were a silver-lead blast-furnace to be run in this way the lead of the charge would be volatilized, passing off with the escaping gases, but copper, being a comparatively non-volatile metal, is not lost to any extent; though, in oxidized copper ore smelting, and in the smelting of copper-bearing slag in the copper region of Lake Superior, one may notice that there is some such loss, as is evinced by the blue color of the rising flame. But, even granting that there is but little loss for this reason, there remains the fact that much heat is uselessly escaping that should be utilized at the tuyeres where it is needed to keep the tuyere zone hot. Two things would contribute to this. First, feeding and operating the furnace so as to keep down overfire as much as possible, and second, diminishing the fuel, while at the same time heating the blast. As regards the first factor, much more can be done than is generally accomplished by packing the charge, keeping the shaft clear and free from accumulations, feeding large charges properly segregated, keeping the tuyeres open, and feeding fuel to come down in front of them. As regards the second factor, hot or even warm blast has been found to greatly assist in increasing heat at the tuyere zone, and thus bringing the furnace into the best condition. I have seen copper matting furnaces (especially those devoted to the smelting of roasted leady copper matte), run with but little overfire—certainly without the excessive heat to be observed in the operation of so many of those that are ordinarily run. I am of the opinion that such conditions need not necessarily exist, and that they can be improved to a greater or less degree. I would like an expression of opinion, and especially a statement of what has been accomplished by smelting men in this way.

A PATENT issued to a railroad company is presumptive evidence that the land was at its date non-mineral. It is not open to collateral attack any more than an agricultural patent would be. If, at the date of the issuance of the patent, there was upon the ground an actively and profitably worked mine, the aid of the Government might possibly be secured to vacate the patent at the instigation of the mine owner or his successor in estate. No locator, however, not connecting himself with a valid mineral right subsisting at the time the patent issued would have any standing whatever in court, and could not assail the railroad title. This, of course, includes one who has located the ground since the railroad patent was issued.

MINING AND METALLURGICAL PATENTS.

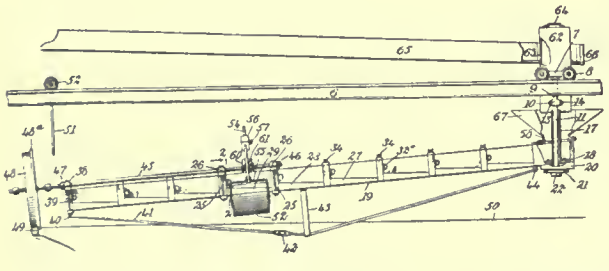
Specially Reported for the MINING AND SCIENTIFIC PRESS.

CONCENTRATOR.—No. 838,468; John P. Shumway, Los Angeles, California.



The herein-described apparatus for separating ore without the use of water, comprising a plurality of concentrator-tables pivotally mounted in a supporting frame and arranged to normally have an inclination downward from the head to the foot thereof, one table being mounted higher than the other and arranged to discharge the waste from the first or highest table onto the table next below the same; an air-tight casing beneath the canvas top of the table, a canvas or covering thereon and means to vibrate said covering; means to supply air to the air-chamber below the covering; and means substantially as shown to impart a vibratory motion to said table in combination with a carrying belt disposed below the concentrator-table and adapted to receive the contents of the table when the tables are thrown into the vertical position, the said carrying-belt extending under all the concentrator-tables and being operatively connected with the main driving-shaft and arranged to carry the material dumped thereon into a receptacle and means to feed the tables with the substance to be operated on.

PULP-DISTRIBUTER.—No. 838,196; David Lonie, Fairview, British Columbia, Canada, assignor of one-half to Henry Lee, Fairview, Canada.

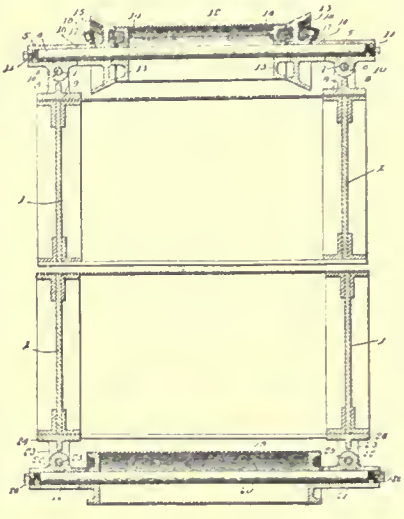


In a pulp-distributer, the combination of a chute, means for rendering the same movable upon a centre, a revoluble shaft connected with said chute and provided with a revoluble member, a track for supporting said revoluble member, a pan mounted upon said chute and adapted to be filled, and mechanism connecting said pan with said revoluble member for the purpose of moving said chute.

STAMP-MILL.—No. 838,190; Peter Kirkegaard, Deloro, Ontario, Canada.

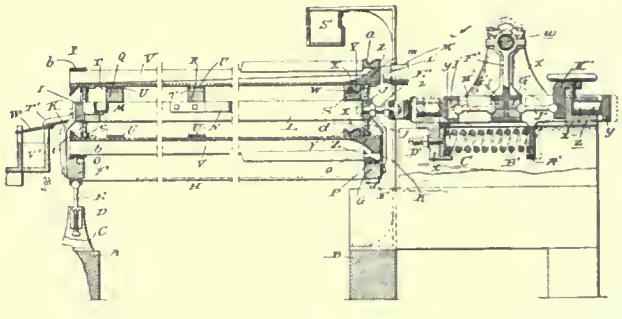
A means for hanging up the stamps of stamp-mills, comprising a tube or sleeve, hinged at a fixed point on the stamp-mill and arranged to swing into the path of the tappet thereof, a rod telescoping therein and having a roller within the sleeve, a cam pivoted within the sleeve and acting through the wall thereof on said roller, and a handle whereby the sleeve is initially located beneath the tappet and the rod subsequently projected therefrom by the cam so as to lift the tappet into inoperative relation.

CONVEYOR.—No. 838,119; George W. King, Marion, Ohio, assignor to the Marion Steam Shovel Company of Marion, Ohio, a Corporation of Ohio.



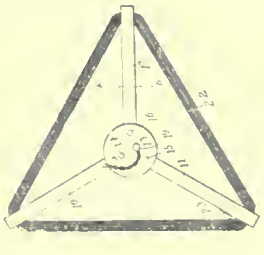
In a belt conveyor of the character described the combination with a stacker-frame, of belt-supporting rollers, rotating shafts on which said rollers are mounted, and end-supporting bearings for said shafts, each bearing comprising a bearing sleeve to receive the shaft and a base or bracket secured to the frame, said sleeve and base being connected by a pivot transverse to the shaft, substantially as described.

ORE-CONCENTRATING TABLE.—No. 838,058; Frederic W. Sherman, Park City, Utah.



In an apparatus for treating pulp, slimes and the like, the combination of a receptacle for receiving the material; means for imparting a reciprocating movement thereto; means independent of the reciprocating means for abruptly stopping the movement of the receptacle in one direction; and means for imparting to the receptacle as it is moved in the opposite direction a jar or impact in a plane approximately vertical to the longitudinal axis of the receptacle.

SURVEYOR'S REEL.—No. 837,931; Edward H. Holden, New York, New York.



A reel composed of a pair of disks, an arm immovably secured thereto; a pair of additional arms pivoted to the disks, means for limiting the movement of the pivoted arms, and means for locking said arms, substantially as specified.

The Deister Concentrator at the Baltic Mill.

Written for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

The Baltic mill, at Redridge, Michigan, recovers native copper from an ore containing about one per cent of the metal. The copper is in part finely knit or disseminated through the rock, so that to recover this, fine crushing is needed. Now, to work such slimed material, a minimum supply of wash-water and an opportunity for the quiet settling of the heavy particles are needed. This

The Deister Concentrator.

the Deister people claim they have attained in their machine to a greater extent than in any other similar table-concentrator. With the same stated capacity, the table has but half the area of its competitors, and is operated at the high speed of 320 revolutions, or 640 strokes per minute, but with the consumption of one-fifth of a horse-power only. Because of its smaller dimensions one notices but little of that vertical vibration which tends to throw the surface of the water-sheet into transverse ripples. One may say that the longer table has a nodal zone of vibration, and here there is less chance for quiet settling as compared with the smaller table. Again, the Deister table has three higher riffles or strips, serving to make a quiet pool or pocket where the heavier ore particles are brought to rest and travel along, sheltered by the riffle, to the point of discharge.

When the Deister table was first introduced in an experimental way at the Baltic mill, tests were made with it as against the Overstrom table, and with the same feed, as well as the same tonnage put through. The tests were so satisfactory for the smaller table that it was decided to put in a complete set of ten of them to take care of the discharge from a single stamp. This was classified by a new design of settling-box or classifier, which delivered two classes of stuff, the coarser going to four tables and the finer to six others, thus giving better classified material than that of an ordinary settling-tank as heretofore used. This settling-box may be described as follows: The launder, taking the overflow of the Tamarack classifier and from which the jig stuff had been removed, delivers to a screen box 3 by 8 ft. having a false bottom pierced with 3/16-in. holes, which removes chips and small pieces of wood. The pulp passes to a V-bottomed settling-box 6 by 8 ft. area, where the coarser pulp is taken out at four gooseneck spigot-discharges to four of the Deister tables. The overflow of the small settler is distributed evenly to the large V-bottomed settling-box having a projected area of 11 by 28 ft. Six Deister tables take the six gooseneck spigot-discharges from this box. The overflow is upon three sides of the box, equal to 68 linear feet in all, and still carries some 60 tons of dry material in 24 hours. The surface of the liquid in the box appears to be quite quiet. In spite of such careful settling it is possible to pan out and find copper in the heavier portions of the overflow which now runs to waste. The gooseneck discharge pipes, already referred to, rise from the lower part of the settling-box or tank to a height such that a flow is still ensured. The use af them has the effect of giving a thicker product than if one used the direct spigot-discharge.

A series of comparative tests were made between the Overstrom and the Deister tables, the former, however, taking its supply of an unclassified and coarser stuff from a small settling-tank of the ordinary design, while the Deister obtained a more uniform product from the large settling-box above described. The results were for the average percentage of extraction:

	Mineral alone.	Mineral and middling.
Overstrom	53.1%	65.2%
Deister	56.6 "	68.8 "

Upon panning the tailing from each table the writer found, as far as could be judged by eye, that the tailing of the Deister contained but one-third as much metallic copper (in flaky form) as the larger table, showing the superiority of the new table in the separation of this kind of material. The ore, besides native copper, con-

D, Secondary V-tank, 12 by 30 ft. by 8 ft. deep. Circumferential overflow. Fine slime from this tank goes to six tables.
E, Three-way cock, with 1¼-in. pipe, fitted with goose-neck having hydraulic connection.
F, Three of these on small tank and six of them on the large one.

Sketch Showing Method of Distributing Slime in Large Rectangular V-Tank. Contributed by F. G. Coggin.

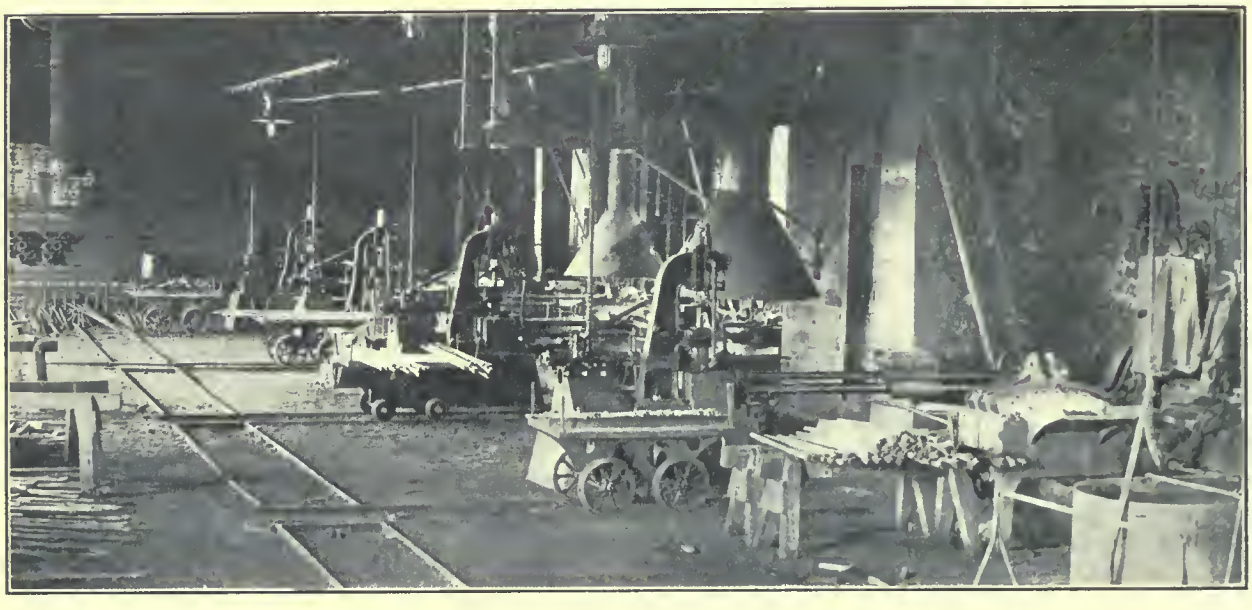
tains chalcocite, and it is this latter mineral that has probably been as well separated on one table as on the other.

It is intended to put an Overstrom table in use on the classified stuff of the new settling-box for the purpose of comparing it directly with the smaller table, and until this is done final judgment must be reserved.

In this experiment the personal equation comes in, men doing better work upon the table to which they are most accustomed or which happens to suit their particular characteristics.

A Modern Drill Shop.

An interesting feature of the Quincy Mining Co.'s plant at Hancock, Mich., is their drill-shop equipment, illustrated in the accompanying engraving. The shop, which is 40 by 80 ft., contains four drill-sharpening machines of the Word Bros. type; two of them are used to sharpen the chisel-bit drills and the other two handle the cruciform steel. A large steel tank, partly shown at the right, is used for tempering the steel. A car-track running lengthwise with the shop and four turntables, with short tracks leading therefrom, enables the attendant to keep the dulled drills up to the machines and to take the finished drills to the tempering tank without interrupting the operators of the sharpening machines. Special coke furnaces are used for heating the steel. New drills are forged almost as rapidly as old ones are sharpened. With four men to operate the machines and one man to attend to the tempering and distributing, an average of 2,500 drills per day are handled in this shop.



A Modern Drill Shop.

Commercial Paragraphs.

THE SEASHORE REALTY CO., of Long Beach, Cal., has opened a free reading room for mining men and has the leading mining papers on file.

THE H. W. JOHNS-MANVILLE CO., of New York, will open a New Orleans branch on January 1. This will consist of a large retail store, offices and warerooms, situated in a three-story building at the corner of Baronne and Perdido streets.

JOS. RETALLACK, 1701 Blake St. Denver, manufacturer of the new Eclipse Drill Maker and Sharpener has ten of his machines in operation at the large mines of the Cripple Creek district; also has a number in Montana, Arizona, and Mexico. The manufacturer claims this machine will make drills complete with round, square, hexagon, or octagon shank from the steel bar without any hand work whatever. Any form of bit, cross, X, Y, or chisel point formed with accuracy in one heat. He also manufactures an automatic tempering machine for use in connection with the drill-sharpener.

A New Gold Saving Machine.

The problem of saving fine and flaky gold, either in placer gravel or mill pulp has, to a large extent, been solved by the Schutz Separator, a new machine now being put on the market by the Schutz Separator Co., of 939 Oak St., San Francisco. The machine is compact and has large capacity. The material to be treated is conveyed into a revolving hopper, which distributes the load evenly within an inner shell over revolving flexible flat steel brushes confined within that inner shell, which is 12 in. less in diameter than the main tank. There are two sets of revolving brushes, each set containing 12 arms and having 10 brushes to each arm. These sets of arms are fastened on a main revolving hollow shaft, one above the other, at an interval of 12 in. The brushes are fastened on these arms so as to interlock and move in opposite directions. All material to be concentrated must pass through this system of brushes, and thus every particle of gold is thoroughly separated and cleaned. The inner shell extends about eight inches above the main tank to prevent any material from flowing direct from the revolving hopper over the main tank into the waste sluice; while the lower edge of the inner shell extends to within eight inches of the bottom of main tank. The pulp, in its downward course, comes in contact with the revolving pipes, ejecting water from its perforated holes, separating and precipitating the gold, while the lighter and baser material escapes from under the inner shell and is forced upward over the main water tank into a circular sluice to the waste dump. These revolving water-pipes are fed from the hollow shaft in the centre of machine. There are 32 of them, and they extend from the centre receiver like the spokes of a wagon wheel, although connected to a circular rim. They are perforated with two rows of small holes. One row of holes is on the bottom of the pipe, the other on top. The bottom slopes outward so as to assist the concentrate to gravitate to the outer edge. The concentrate escapes from the main tank through suitable openings in the bottom.

A small particle of gold, thoroughly scoured and cleaned, has greater specific gravity according to its bulk than any other mineral, and will sink against the force of water applied from these revolving pipes, while the light and bulkier material — usually of no value — will be forced upward into the waste sluice. The amount of water required to operate this separator is half of a miner's inch to every square foot of area, while every corresponding square foot of area will separate and concentrate 500 lb. sand per hour. The necessary fall of water will not exceed 20 ft. vertical. The machine has been in practical use for three years; it is made in three different sizes, namely, 6 ft., 8 ft., and 10 ft. diameter. One of the 6-ft. diam. Separators is now on exhibition at 1371 Harrison St., San Francisco.

Editorial.

A CORRESPONDENT who is thoroughly familiar with the coal business of the Middle West contributes, in this issue, a useful article on the shortage of cars and the cause of it. One remark is particularly worth emphasizing, and that is the reference to the time devoted to the ticker on the part of traffic managers. This is too large a subject for a paragraph, but we may note that the biggest railroad operator in the country was once a Wall Street broker, and does not disdain even now to juggle with a declaration of dividends so as to make a neat little clean-up for himself and his associates.

WE CONGRATULATE Mr. Lewis E. Aubury on his re-appointment as State Mineralogist. It does scant justice to him and puts Governor Pardee in a poor light. After hesitating for two years, the Governor makes the appointment just at the moment when his power is about to be transferred to another executive. During the interval the Mining Bureau has suffered by having a chief whose tenure of office was uncertain. This is an example of the play of small politics on appointments that should be wholly divorced from political considerations. The office of State Mineralogist should be treated as one coming under the civil service rules, and a man who performs the duties of it faithfully should have the first claim to succeed himself. We believe that Mr. Aubury has served the State faithfully, and we record his re-appointment with pleasure.

WE TAKE PLEASURE in publishing a letter from Mr. Charles G. Yale, commenting upon some recent remarks appearing in these columns. No one is so well qualified as Mr. Yale to speak on mining matters in California or to discuss the status of the Miners Association. It appears that the term 'coterie' gave umbrage, but reference to any dictionary will show that it is in no sense disparaging, for it means a group of persons who meet together for social or scientific purposes. Certainly no offense was meant. The incident illustrates anew the danger of departing from the use of good straight English, and for this lapse we apologise. It is unfortunate that interest in the Association has been so slight during the last two or three years that its affairs have had to be managed by the same group of men, to whose public spirit the organization owes its survival. Without being destructively critical, we venture to say that this decrease of interest was inevitable in the face of the decline in hydraulic mining and the lack of real progress in the efforts to solve the debris problem. Mr. Yale's figures are eloquent in this regard, and we join with him also in hoping that the scope of the Association may be enlarged so as to make it truly worthy of its comprehensive title. The new president, Mr. William C. Ralston, is an enc

getic and capable mining engineer and he should be able to enlist active support in giving effect to a broader policy. We look to better days for the California Miners Association.

On another page we give a letter from Mr. James W. Abbott, a mining engineer of proved experience, describing the new camp of Greenwater as he saw it. No locality has been used so recklessly for irresponsible mine promotions, the latest being a two-million dollar incorporation offering shares at half-price on the slender evidence of a lot of windy talk. Mr. Abbott may be severe in his judgment, but he is without prejudice. From other sources we learn that sulphide ore has been found in some of the shafts and that one or two companies are doing systematic exploratory work, so that trustworthy evidence should soon be forthcoming. The large outcrops mentioned in the daily press are, as Mr. Abbott clearly describes them, zones of fracturing, stained with copper and iron minerals; in these, ore containing 10 per cent of copper has been found in places, but continuity is yet to be proved. Owing to the practice of sinking vertical shafts instead of following the ore on the dip of the lode, there is a delay in exposing the nature of the deposit; it may be debated whether it is better mining to sink on the ore or leave it on one side in order to put down a vertical shaft, but the fact remains that the more dilatory tactics are extremely convenient to promoters who are afraid of being handicapped by too many facts.

Writers in mining papers occasionally do a wrong thing, without perhaps realizing it, in citing geologists as authority for their own statements on the science of ore deposition. From a recent news-letter we quote the following: "The presence of chrysocolla and fluorite in the east-west cross-course veins in this district is proof positive of great depth and strength, for invariably the ledges widen as they go down. Another strong argument in favor of ledges of this character is that according to the opinion of the best geologists in this country, notably J. E. Spurr, in his report on the 'Geology of the Tonopah District,' they invariably achieve a depth at least as great as the payable outcrop on the surface. Van Hise and Kemp also agree on this theory." In behalf of Messrs. Spurr, Van Hise, and Kemp we can say that no one of these careful observers and thoughtful writers ever said anything of the kind. It is a gross injustice to a scientific man to impute to him a theory for which he is in no way responsible.

Professors at universities all over the country have been pestered with the circulars, letters, and prospectuses of a Colorado marble company promoted by a syndicate in New York. The methods adopted afford an example of a pestilent misuse of the mail service and illustrate the colossal guile of the modern promoter. The marble deposits are stated to be worth $2,800,000,000, from which, after deducting the costs of extraction, a profit of $1,400,000 is to be obtained. Yet all that is offered is a bond issue to the extent of $500,000. As a matter of fact, this marble was not deemed suitable either for the Denver Public Library or the new Episcopal cathedral, because it is so fractured that large pieces of stone are difficult to get. Incidentally, as illustrating how conventions are used nowadays for advertising purposes, it may be mentioned that the chief promoter of this questionable enterprise delivered a speech before the Colorado Commercial Organization, employing the opportunity to parade his scheme and to print his speech for subsequent dissemination among the professors and other people of supposedly simple financial experience.

The London Mining Market in 1906.

Last week we reviewed the manifestations of speculative mining activity in America during the past year; this week we turn to London, which is still a dominating factor in the finance of world-wide mining operations.

The speculation in gold mining on the Rand was practically dead during 1906; but there has been an excited market in diamond shares, due to the great success of the Premier mine and the discoveries made by the New Vaal River Company; there was also some business in Tanganyika copper and in Rhodesia Broken Hill, two stocks representing large enterprises in northern Rhodesia and across the border into the Congo Free State. The Kaffir market, that is, the one devoted to Rand gold mines, has been on the verge of collapse several times, the general trend being steadily downward with but small dealings. The public has abandoned speculation in these shares, which are held mainly by financial houses that are compelled to protect their holdings from further decline. New capital for development or increase of plant is difficult to obtain because political conditions in the Transvaal are once more on the boil, with the utmost uncertainty as to what party or combination of parties will control the situation. In the meanwhile the Chinese labor problem has continued to be an issue in British politics and certain revelations as to the morality of the coolies, together with emphatic assertions by competent men that white labor can be employed economically, have swung sympathy toward the anti-Chinese party to such an extent as to make complete repatriation a possibility. All this has disgusted the mining magnates and intimidated speculators.

The most picturesque feature of mining speculation at London has been the revival of Cornish mining. This, of course, is the direct result of the rise in the price of tin, which reached a maximum of £215 per ton or 46 cents per pound during the year. Appeals to the patriotism of the British investor and to the romantic story of mining in the 'old county' have been successful, with a strong tin market, in raising capital for a large number of ventures, most of which are based on abandoned mines with a past record. Rich ore in the bottom workings of Dolcoath and dividends from four or five mining companies that were almost moribund a couple of years ago have given encouragement to promoters, so that money has been readily obtainable. In Ireland also there has been something of a flutter, but in copper mining. Naturally, the high price of this metal also has provoked speculation and has justified the issue of several

new undertakings. Of these Great Cobar in New South Wales was the most important; other Australian copper mines were placed in London, together with the Penn-Wyoming mines in Wyoming. Rio Tinto shares have reflected the tone of the copper market and formed a lively medium of speculation on a large scale. Several Siberian copper companies floated in previous years were able to command public favor by their cheerful reports and led the way for further promotions and some tall boosting of quotations. In another metal, zinc, business was done through the medium of Broken Hill shares, smelting companies, and concentrating processes, all of which was the result of a recognition of the value of the big dumps at Broken Hill and the possibility of their profitable beneficiation by new methods.

In Mexican shares the market has been rather quiet. The mines at El Oro reported good progress; Esperanza receded from its high price, there being a lack of confidence in the future of this great mine; El Oro made a discovery in the lower levels, and this stiffened the market, while Mexico stock has reflected satisfactory developments in depth. Near the close of the year there was a spurt in San Francisco del Oro, on telegraphic news of a big discovery. Dolores has been steady, with a recent relapse due to the confession of inadequate working capital.

In American mines, Camp Bird shares dropped when the mill was destroyed in March, but recovered to their former price on re-building and the re-commencement of milling operations at the end of the year. Oroville Dredging has been steady, at about par; Stratton's Independence has had the benefit of some discoveries of ore and of schemes to treat the dump, but shares have continued to decline. Tomboy has made a good showing for the year and declared a good dividend, so that the price advanced. In Canadian mines, the former interest in British Columbian ventures is slight indeed as compared to the days of Whitaker Wright, but there have been dealings in Le Roi, both No. 1 and No. 2; while the price of Ymir has slowly dwindled. A Cobalt flotation drew attention to the new camp in Ontario, but the business done was not important.

Dealings in Indian mines are also confined to a small portion of the British public; the yield of gold is declining, because the best mines have passed the zenith of their development, but dividends are steady, and these shares have proved an eminently satisfactory source of income to the holders of them. The West Australian market, like the Kaffir department, has lost its former animation. Mining is proceeding satisfactorily, but with a recognition of the fact that many of the big mines have reached their maximum development. New ventures are few and unimportant. The general public has lost interest in Westralian shares, dealings being confined to a few well-informed people at Adelaide and at London. But there has been no collapse, the market has remained steady; the only big drop was in Great Fingall and the only big rise was in Kalgurli. The Egyptian and West African departments have been without any feature of interest, results at the mines being disappointing.

In the latter part of the year there was a marked revival of speculation, accumulated capital finding employment in creating a boom in Siberian gold and copper mines, the inflation in quotations exceeding 1,000 per cent in a few instances. As Siberia's total gold production is only about $20,000,000, the market value of over $30,000,000 given to the issues of a few English companies operating there, presages either a notable increase of production or an inevitable financial collapse. In November there was a sudden revival of interest in Deep Leads, a group of companies formed to exploit alluvial deposits in Australia, and shares that had been neglected rose to three or four times their previous prices. This led to a reconstruction of some of the companies and the flotation of new enterprises of a similar kind. At the same time diamond ventures in South Africa, especially New Vaal River shares, were bought freely and an excited market prevailed. De Beers rose in sympathy and several dormant stocks were advanced rapidly. In the last week of the year there was a marked recovery in Kaffirs, due to reports of the Boer leaders having assumed a favorable attitude on the labor question.

On the whole the speculative activity of the London market as regards mines has been curiously scattered, the great flow of capital toward South Africa having been arrested and diverted to a multiplicity of channels, with as much willingness to risk money as ever before, but with a growing tendency to demand information more reliable than that deemed adequate in former days.

Standardization.

On another page we publish the report of the Committee appointed by the Institution of Mining and Metallurgy, to report upon the standardization of screens. They recommend the retaining of the term 'mesh', mainly on the ground that it is so fortified by custom that it would be impracticable to dislodge it in favor of 'aperture'. While you are reforming you may as well reform, and there is this to be said of 'mesh' that, in South Africa particularly, it is employed in a most untechnical manner even by the leading metallurgical engineers.

Also, while the Committee undertook to define "sand" and "slimes", they might as well have made it 'sand' and 'slime', putting a taboo on the sloppy use of the plural. Why "sand" in the singular and "slimes" in the plural? These matters are not vital but, like standardization of screens, the correct use of technical terms tends toward definition of thought and clearness of of statement. Those who beggar themselves of the plural find themselves in a dilemma when they desire to speak or write concerning several kinds of a thing. But these remarks must not be taken as belittling the work of the Committee; we are of the opinion that their recommendations will find general acceptance and will be received with gratitude, as helping to lessen the confusion existing in the terminology of screens. The need of agreement in usage is emphasized in the letter from Mr. Robert H. Richards, the authority on ore dressing, whose letter we also publish.

Special Correspondence.

Leadville, Colorado.

Annual Statistics.—Excellent Showing.—Big Production of Zinc.—New Development Work.—Breckenridge News.

Notwithstanding that the Leadville mining district has been handicapped seriously during the past year by car shortage, lack of smelting facilities, and dearth of labor, a good showing has been made. From a thoroughly reliable local source the following statistics are available:

Gold	52,573,386 oz	valued at	$20.67	$1,086,692
Silver	4,889,160 "	" "	0.667	3,265,524
Lead	49,422,753 lb	" "	0.056	2,790,408
Copper	5,466,641 "	" "	0.192	1,049,814
Spelter	110,483,400 "	" "	0.060	6,686,455
Manganese	36,000 tons	" "	8 00	288,000
Total				$15,166,893

The tonnage of the district was divided among the following classes of ores: Lead carbonate, 102,112; iron oxide, 163,760; iron sulphide, 276,109; zinc sulphide, 223,565; silicious, 107,875, and manganese ores, 38,000, making a total of 916,721 short tons.

Attention is called to the enormous increase in the production of zinc, which exceeds the total value of gold and silver; while the tonnage is not what was predicted, it does credit to a district embracing a territory but little over three miles square. The total value of the metal products for 1905 was a little above $13,000,000, against $15,000,000 for 1906, making a total production to date of $353,000,000. The following figures show the tonnage produced by some of the larger companies during the year:

Iron-Silver	145,450	short tons
Midas	143,125	" "
A. Y. & Minnie	88,000	" "
Western	103,045	" "
Reindeer	35,000	" "
Morning Star Con	55.000	" "
New Monarch	25,200	" "
Ibex (Little Johnnie)	80,725	" "
Yak	85,000	" "

Of the ores produced by the camp a large portion (except zinc) was treated by the local smelter, which employs 1,000 men, has in operation 10 blast-furnaces and a capacity of 26,000 to 28,000 tons per month. Of the spelter product all but 7,500,000 lb. was smelted outside the State. A district which in 1906 has prodneed more than 110,000,000 lb. spelter has strong claims to recognition as a producer of this important product.

Prior to 1898 the zinc deposits of this district did not receive particular attention. The low grade of the ore did not permit of its being treated directly except in a few exceptional cases where the product as mined had a zinc value of over 40%. But with the advent of magnetic and static separators the zinc ore is being marketed with a zinc value as low as 18%. Coupling the electric treatment with the high-standard wet-concentrating tables of the present, the mills of Leadville are producing a zinc product of 35 to 45% and above. It may be mentioned in this connection that the district produces but a small tonnage of strictly zinc ore. The supply of zinc is derived from the iron-lead sulphide bodies principally, and belongs to what is styled the sulphide zone. Fortunately for the metallurgist, the zinc carries but a small percentage of the precious metals, which accompany the iron. With the completion of the mills now under construction or enlargement, the total milling capacity will approximate 700 tons per day of crude ore.

Among the producers soon to be added to the Breece hill list is the old Chippewa property. Already the new company operating under the style of Ingomar Real Estate, Mining, & Leasing Co., by raises and drifts from the old workings, has opened up a very good grade of ore and shipments will be made soon. One of the mines of the district that has been quietly making a record during the past year and which has a most flattering prospect is the New Monarch, on Little Ellen hill. This property produced 25,200 tons during 1906 and enjoys the distinction of producing the highest grade of ore shipments. With the completion of the development work as planned for the present year, this mine will stand near the head of the list of important producers. ——The manager of the Wellington mine, near Breckenridge, reports a large ore reserve in that property that will require milling facilities. The Oro and Orthodox groups have been added to the Wellington and will be operated by the Colorado & Wyoming Development Co., which is capitalized at $10,000,000. The company contemplates erecting a 300-ton concentrating mill, and has recently entered into a contract with the Colorado Zinc Co., of Denver, to ship it 75 tons of ore daily. J. T. Hogan, manager of the Jessie, states that the oxidized ores of that property can be treated successfully by the cyanide process, and that a large leaching plant will be installed for that purpose during the present year.

Toronto, Canada.

Mining Under Cobalt Lake.—Prospects at the Nipissing.—New Gold Discoveries.—An Oil Boom.—More Companies Incorporated.—Speculative Activity.—Excitement in Hastings County.—Coal Mining in Nova Scotia.

The syndicate that last week purchased from the Ontario Government for $1,085,000 the mining rights to the bed of Cobalt lake, will turn over the property—at a substantial advance, of course—to the Cobalt Lake Mining Co., which has just been organized for the purpose of developing it, with a capital of $5,000,000. The carrying out of the scheme has been attended with a good deal of trouble and dissatisfaction, as the amount of money required by the syndicate to effect the purchase was considerably oversubscribed, and many of the would-be ground-floor participants have been left out. Litigation has already resulted. The following directors have been elected: Sir Henry M. Pellatt and Britton Osler, of Toronto; T. Birkett, G. F. Henderson, D. B. Rochester, H. S. Southam, and Frank Latchford, of Ottawa; John H. Avery, of Detroit, and G. E. Drummond, of Montreal. The company will proceed with active mining operations as soon as possible. As the gravel of the bed of the lake is rich in silver, dredging may be undertaken, in addition to sinking a shaft and driving under the water, which is about 40 ft. deep.

Charles A. O'Connell, manager of the Green-Meehan mine, reports that high-grade ore is being taken out at the rate of about one ton per day. A car of ore will shortly be sent to the smelter at Copper Cliff, Ontario—instead of to New Jersey—as an experiment. A statement to the stockholders of the Nipissing handed out on December 26 (in connection with the payment of a quarterly 3% dividend and an extra dividend of 2%) intimated, on the authority of the superintendent, W. H. Linney, that during the two years of operation $2,500,000 worth of ore had been mined at a total expenditure for all purposes of $225,000. Only six veins on the property are being worked. The decrease in value in the ore of vein No. 19 is admitted. The production for the last four months has averaged about $200,000 per month, but will probably be less during the winter months. Owing to the time of year no new exploration work can be done on the unprospected property, but such work should be promptly undertaken in the spring. The character of the mining is such that it is impossible for any one to determine the number, width, depth, or value of ores exposed on the

surface or to be exposed under the surface that could be developed on the portion of the property which has not been deforested. The company has produced more than $2,000,000 net from an area of less than 10% of the total acreage of the property.

A rich find of gold at the Minnehaha mine, on Minnehaha lake, in the Manitou lake district, northwestern Ontario, is reported.——The Pearce mispickel mine in Marmora township, Hastings county, Ontario, which has laid idle for several years, will shortly re-open. It carries a good percentage of gold with arsenic and the increased price for arsenic encourages the belief that it can be profitably worked.——The Hickey Oil Co., of Detroit, operating in the Leamington-Comber oilfields in Essex county, Ontario, has wound up its affairs. It struck oil rich about two years ago, but the gushers did not hold out. The company disposed of about $15,000 worth of oil, and drew $7,000 in bounties from the Canadian Government, but the cost of machinery and well construction absorbed its funds and the total losses will be about $14,000.——An oil boom is on in Manitoulin island, Lake Huron, where about 100 wells have been sunk at a cost of about $500 each. It is claimed that St. Joseph's island, near Sault Ste. Marie, is in the same formation and has similar oil-bearing qualities.

There were 17 Cobalt, Larder Lake, and other mining companies incorporated this week, with an aggregate capital of $17,150,000, and this is by no means a record week either. Most of them will issue dollar shares. The largest capitalization is that of the Nipissing Copper & Silver Co., Toronto, $3,500,000. The mining rights to the bed of Kerr lake, Cobalt area, about 23 acres in extent, recent tenders for which were declined by the Provincial Government as not being high enough, are again offered for sale. The new tenders will be subject to a royalty of 10% on the gross value of the output.

There is great excitement in the Hastings mining district, in eastern Ontario, over the discovery of a rich vein of gold-bearing ore about nine miles north of Madoc village. It was found by E. B. Davis, an experienced man, who has been engaged in local mining for many years. A sample weighing about 10 lb. has been brought to Belleville and closely inspected by experts. It consists of milky quartz, dolomite, and black country rock, thickly studded with gold, which shows in specks in both the quartz and the dolomite. Particulars as to the extent of the deposit have not transpired.

The Dominion Iron & Steel Co., of Sydney, Nova Scotia, in which Toronto capital is largely invested, having had considerable trouble over the coal supply for which they had contracted with the Dominion Coal Co., have determined to mine their own coal. They have just concluded an arrangement to purchase from Thomas Routledge, and others associated with him, large areas in the immediate neighborhood of their works at Sydney; these they will develop as soon as possible. The capacity of the coal measures secured is estimated at several hundred million tons of coal, which will enable the steel company to export largely in addition to satisfying their own requirements.

Republic, Washington.

Review of Progress.—The Methow District.—Much Activity in Okanogan County.—Chelan District Prospering. — Exploring the Colville Reservation.—The Metalline District.

In the Methow district, during 1906, the Antimony Queen Co. operated the Dixie Queen mine, and shipped several large slabs of stibnite that weighed from 500 to 1,000 lb. each. Since then the company has been shipping ore in carload lots. The Seattle Smelter Co. has ordered machinery for a 10-ton furnace to be installed on the Gold Creek antimony belt next spring, and if it proves successful a plant will be installed to handle the entire output of the district.

In the old Ruby camp, near Conconnully, the Ruby mine, controlled by Johnathan Bourne, of Portland, Ore., has been largely exploited by shaft and tunnel work, but on the plan of sawing wood and saying nothing. The Arlington group, adjoining, which has thousands of tons of ore blocked out in the underground workings, was equipped with a hoisting and compressor plant, and considerable work was done in the mine. Minneapolis people purchased the Ruby-Payne and Seligman group of claims last summer and started extensive exploratory work on them.

The western part of Okanogan county showed more than usual activity during 1906. In the Twisp district a fine body of ore was struck in the Capital mine, and the company contemplates the erection of a mill. On the Red Shirt mine, adjoining it, a large amount of exploratory work was done, and the owners are figuring on hoisting machinery. The Alder mine is coming to the front; for twelve years the original owners held it, content with performing the annual assessment work. Anywhere at the suface the quartz will pan gold to the extent of $10 per ton. Three years ago systematic development was started, and three tunnels have since been driven. The No. 1 cross-cuts the vein at a depth of 50 ft.; at that depth the vein is 40 ft. wide. On that level traces of copper were found, but the gold is in pyrite and will not pan. The No. 3, or main adit, was started last year and driven 200 ft. It is expected to tap the vein at a depth of 400 ft. The Alder group comprises three claims on a vein that has been exposed by open-cutting at different points for a distance of one and one-half miles. Railway transportation will soon be available between Wenatchee and Oroville, over the V. V. & E. branch of the Great Northern system. A survey has been made for a connecting branch to the Alder mine, 30 miles, following up the Methow river from Potero to the Twisp, which empties into it The post-office town of Twisp is situated at the confluence of the two streams. The Bonita, on Slate creek, one of the oldest mines in Washington, with a vein 60 ft. wide of milling ore, was comparatively idle for several years until 1906, when the management passed into the hands of A. W. Hawks. A 10-stamp mill was built, and the first brick under the new administration was turned out early last fall. The mine has enough ore blocked out to last for several years. The present output is 30 tons per day, but with additional milling capacity this will be increased. The Lane process is used, and a saving of 95% is reported.

The Chelan district has a number of excellent outcrops, on which considerable work is being done, and while they have not been developed into paying mines, they are a good deal more than mere prospects. The orebodies are large and the values fairly good but the lack of transportation has retarded development. Last winter J. P. Graves took a bond on the Holden property and last spring he started work and has employed ten or twelve men on it ever since. When Mr. Graves took hold of it, he thought it was a low-grade copper property, similar to the Granby, but the work done has demonstrated that the new bodies of ore may be classed as high grade. This property is situated on Railroad creek, about 15 miles west of Lake Chelan. Already over 300 ft. of depth has been attained on the vein, and the No. 3 adit, which will be continued all winter, will give a depth on it of 550 ft. The vein runs the length of three claims and at the surface is approximately 100 ft. wide. The ore is valuable chiefly for copper, but gold also occurs. The No. 3 adit is cross-cutting for the vein and is expected to tap it shortly. The Chelan mountains are

precipitous, and on account of the topography and the magnitude of the vein, it will be possible to glory-hole the orebodies, as is usual in the Granby mines. A smelter will have to be established on the ground to take care of the output, and it will therefore take some time to put a mine on a dividend basis. A survey has been made for an electric railway from Lake Chelan to Spokane. Holdings on the lake and Chelan river have been acquired for the development of electric power on a large scale, and the future of this region is auspicious.

All of that part of the Colville Reservation in Stevens county, tributary to Orient, in Ferry county, has experienced unprecedented mining activity. A view from the heights above Orient, is sufficient to convince one of the unqestionable importance of the surrounding area in comparison with other districts in eastern Washington and British Columbia. The prevailing rocks are granite, gneiss, and schist, and these formations are cut by andesite dikes. The ore is in fissures and on contacts. Veins of pyrite, assaying in gold, silver, and copper, are usually of great width. Under competent management several mines in this region, including Kettle River and Pierre Lake districts, have demonstrated their worth within the year just past. Among them are the First Thought, Napoleon, Easter Sunday, Orient, Pomeroy, Chief & Butte, Minorca, Swamp King, Abe Lincoln, Globe, Regina, Copper Butte, American Flag, Trojan, Tenderfoot, Big Iron, Defender, and Golden Crown. The First Thought mine, owned by Patrick Burns, has opened up considerable ground, from which ore was shipped steadily during the past two years, and the yield of gold was larger than that from any other mine in the State for the same period. Last November an aerial tramway was constructed from this mine to the railway, and now the output will be steadily increased. The ore is purely gold-bearing. The vein is a contact between granite and porphyry.

The Napoleon mine near Kettle river, about 10 miles south of Orient, produced about 11,000 tons, which came mainly from surface quarrying. This mine was purchased by the British Columbia Copper Co. for the purpose of supplying its smelter at Greenwood, B. C., with basic flux. The ore is iron sulphide and contains gold and copper. During the year a great deal of underground work was completed. The company has made arrangements for the construction of a tramway and expects soon to install extensive machinery, with a view to increasing the output to 500 tons per day. On Sulphide mountain, the Easter Sunday mine, owned by the Waukegan & Washington Mining Co., was explored by crosscuts, and ore, rich in gold, silver, and copper was uncovered. The vein is 20 ft. wide. This mine is one of the best equipped, as regards machinery, on the Reservation. Two 100-h.p. boilers and machinery of the most modern type was installed, and close to $100,000 has been expended upon the property. The company expects to build a mill, and in the meantime will ship its ore to the smelters. On the Orient $40,000 has been expended in development and equipment. It has a compressor plant and steam-hoist. Considerable ore, carrying copper and gold, has been piled up on the dump, but the mine has not yet entered the shipping list. The main adit has been extended and the vein was intersected at a depth of 250 ft. Within this part of the Colville Reservation there are a number of first-class prospects that may become productive with exploration. Last year a large number of veins were uncovered, and the district is constantly commanding fresh capital for purchase and development. The whole area surrounding Orient is heavily timbered and well watered, and the transportation facilities are excellent.

The Metaline district became prominent last year through its deposits of silver-lead ore, the principal mines being the Morning and Mammoth. Several other companies are operating in the district, and a large amount of work was done, chiefly in tunneling, the particulars of which were recorded in this journal through the year. Cedar Canyon district has also experienced prosperity, mainly through the purchase of a group of claims, on which a good quality of tungsten ore was discovered, and the introduction of capital by the Krupp company, of Essen, who purchased the claims last fall and have since been industriously blocking out ore, on which 40 men are employed. This company has ordered a concentrating plant at a cost of $80,000.

In the Chewelah district, some discoveries of copper were made last year, and the development of rich silver ore in some of the mines was reported. The United Copper Co. purchased three claims and a fraction for $25,000, and it owns five others. The company sank a shaft on a vein four feet wide at the surface. At the depth of 150 ft. the vein was cross-cut and found to be 40 ft. wide, 18 ft. of it being good copper ore. The shaft was sunk to the 200-ft. level, where the vein was again intersected. A contract was made for 1,000 tons of ore to be delivered to the Northport smelter. The ore contains an excess of iron and carries gold and copper. The company pays $1 per ton for hauling to the railroad and $2.50 per ton for freight by rail and treatment. The ore is trammed from the shaft to the wagon-road, near the portal of the adit. The Jay Gould mine became a shipper of silver-lead ore to the Tacoma smelter last fall, and the returns from the last carload showed a yield of 45 oz. silver per ton, without sorting. The main shaft is down 200 ft. On the 100-ft. level the vein is 25 ft. wide.

Butte, Montana.

Re-Opening of the Blue Bird.—A Mine with a History.—Butte Central Acquires More Property.—Another Consolidation.—The Gagnon Being Developed.—A Liquidation.—Views of Rossi.—Mining in the Coeur d'Alene.

It is stated that the Blue Bird mine is to be acquired by a syndicate headed by Arthur P. Heinze, of New York, vice-president of the United Copper Co. and brother of F. Augustus Heinze. The intention is to organize a development company, and later, if results justify it, to reorganize as a mining company. The Blue Bird is situated a few miles west of Butte, and 15 to 18 years ago was a good silver producer. The property was backed by the present Lord Overbury (formerly Sir John Lubbock) and his son-in-law, Ferdinand Van Zandt, was manager of the property. The mine was splendidly equipped and a 90-stamp mill was erected. Owing to the disappointing returns from the mine and the consequent suicide of Van Zandt, the mine was shut down and for 15 years it has been idle; the surface plant has been torn down and carted away, and no work has been done except by a few lessees, who have been gophering near the surface, taking out some good silver ore. The Blue Bird shaft is 700 ft. deep and nearly filled with water. Prior to 1893 this part of the district was very active, and three or four other mines were good silver producers. The Davis-Daly Estates Co. owns three good claims there, namely, the Great Republic, Last Chance, and Hibernia, all of which have been developed. The Anaconda Co. owns the Nettie claim, which has been opened to a depth of 400 ft. The Trenton Co., another amalgamated concern, owns a number of claims, including several developed properties. The Hibernia, Nettie, and Burlington, in addition to the Blue Bird, have been the chief producers. For 12 or 15 years, however, these mines have shown no signs of life and have been in the

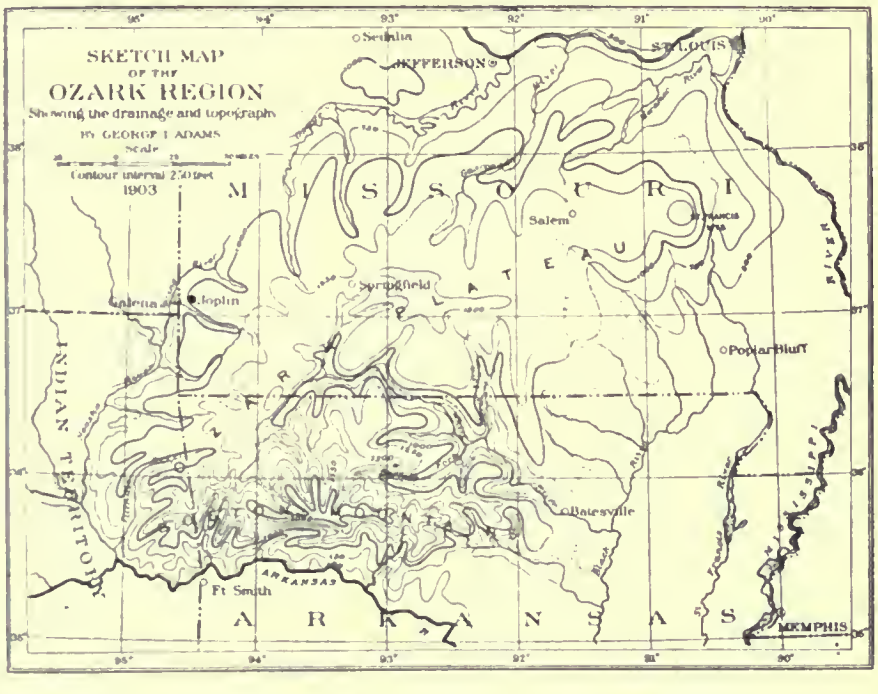
care of watchmen. It is the opinion here that some of these properties could again be worked for silver at a profit, and that with greater depth copper would be found. It is understood that the interest Mr. Heinze is taking in the Blue Bird is independent of his brother and the United Copper Co.

The Butte Central & Boston Copper corporation has secured possession of some ground in the northeastern part of the Butte district that has been taken up on leases and options by a concern known as the Butte Northern Copper Co., but which could not handle the property. It is stated that the Butte Central & Boston has also acquired other ground in the same vicinity, giving it between 90 and 100 acres of mineral ground lying between the properties of the Butte & Bacorn and Butte & London. A large vein outcrops in one of the claims taken over from the Butte Northern. It is the intention of the Butte Central to equip the new purchase and begin development work immediately. The new acquisition is about three or four miles northeast of the Ophir mine, the other property purchased by the same company. The development work on the Ophir is progressing satisfactorily and the big orebodies found on the 300 and 500-ft. levels are being opened up.——The Butte-Milwaukee Co. has begun sinking its new shaft on the Colonel Sellers claim, but the work is handicapped by the fact that therailroad spur has not been completed to Sellers and it is difficult to get timbers and supplies to the ground. Negotiations are on foot for a consolidation of the Alliance and Farrell mining companies, and the the prospects are that a merger will result as soon as terms can be agreed upon.

The shaft of the Gagnon mine, owned by the Trenton Co., has been sunk to a depth of 2,100 ft., at which point a station is being cut. The vein is close to the shaft; it is the vein that dips from the Clark Original mine on the east; it was found on the 2,000 by the Trenton and as it has a flat dip it was concluded that 100 ft. deeper would bring it entirely within the Gagnon ground. The experience of the Trenton Co. with the Gagnon is but a repetition of the experiences of other companies in the Butte district. The upper workings yielded only silver ore, and when the silver deposits gave out it was surmised that the Gagnon had been worked out. That was its condition when it became the property of one of the Amalgamated subsidiaries. Exploration was resumed, with the result that good copper deposits have been opened, and the prospects are that the Gagnon will become a big producer of copper.

The Boston & Montana Co. has reached a depth of 100 ft. with its big three-compartment shaft on the Badger State. This claim has the extension of the rich vein of the Jessie mine of the North Butte Co. The shaft is to be used for the development both of the Badger State and the Aurora, an adjoining claim owned by the same company. The shaft will be sunk to a depth of 1,800 ft. before any attempt is made to develop the vein; it is equipped only with a small and temporary engine, but a large one has been ordered.——The affairs of the Black Rock Mining Co. have been wound up, and the company has practically gone out of existence. It was working the Black Rock mine under a lease and has sold its interests to the Butte & Superior Copper Co., which is now in possession of the mines, including the Niagara, Raymond, Jersey Blue, and Constitution. The new company is sinking a big and deep working shaft on the Black Rock, through which the entire group will be worked.

The Amazon-Butte Mining Co., under the direction of John Hewett, formerly superintendent of the Gagnon mine, is making rapid progress in shaft-sinking on the West Altona, a depth of more than 100 ft. having been attained. The shaft is being strongly timbered and will be taken several hundred feet deeper as rapidly as possible. Some cross-cutting may be done at the 200-ft. level, but there will be no interruption to sinking. Good ore near the surface is being mined by lessees, who are paying royalties. The company itself is after the big fault-vein of the Bullwhacker, which is known to pass through the Altona.——Herman J. Rossi, mayor of Wallace, Idaho, has been on a visit to Butte. He says that Butte capital is responsible for the present boom in the Coeur d'Alene, and that the output of the region has been doubled as the result of it. Mr. Rossi thinks the Snowstorm mine at Mullan, in which the Greenoughs are largely interested, is one of the greatest copper mines in the world, considering its stage of development, and that the Stewart, owned by F. A. Heinze, will also turn out a big producer. He claims that there are more opportunities open in mining in the Coeur d'Alene than anywhere else in America, and that the results are quicker and larger.



Joplin, Missouri.

Record Output for 1906.—Lead and Zinc Production Increased.—Comparative Statistics.—Local News.—Several New Finds.—Successful Leasing.

In the year 1906 some history was made for the zinc and lead districts of southwest Missouri and southeast Kansas, for all previous records were broken. Many new mines were put into operation during the year, many more are being discovered daily, and while 1906 reached the highest mark, the new year gives promise of doing even better if the weather conditions are favorable and the price of both lead and zinc remain where they are. The highest price paid for zinc ore last week was $19.50 per ton; for lead ore, $87 per ton. The highest price of zinc

ore in 1906 was $54 per ton in January; the highest price in the previous year was $60. The highest price of lead ore in 1906 was $87 the last week of the year, against $80 the year before. The shipment for last week was: Zinc ore, 10,780,080 lb., valued at $240,186; lead ore, 1,702,930 lb. valued at $70,510; combined value, $310,696. The shipment for the 52 weeks of the year was: 557,859,470 lb. zinc ore valued at $12,079,602; and 78,377,950 lb. lead ore valued at $3,048,573, with a combined value of $15,128,175. The shipment for the year 1905 was: Zinc ore, 504,801,940, valued at $11,334,320; lead ore, 63,758,700 lb. valued at $1,968,480; combined value, $13,302,800.

George E. Ladd, of the Rolla School of Mines, who has been operating in this district for several years and who is now mining on the Bruce land at Belleville, is opening up a good prospect at a depth of 97 ft. He has cut into the orebody a distance of 20 ft. and has found an underground cave lined with zinc and lead ores. The cave has been explored a distance of 100 ft., showing the same deposits of ore all the way. Several of these cave formations have been encountered in the Chitwood district by other companies.

The American Zinc, Lead & Smelting Co. has just completed the third 600-ton concentrating plant on the property between Carterville and Prosperity, and it will be started up within the next few days.——The German-American Mining Co., operating on the Vantage Co.'s land north of Webb City, is now opening up a 14-ft. face of rich zinc ore.—The first turnin of lead ore from the mines at Springfield, Mo., was made last week and consisted of 88,000 lb. The Trolley Mining Co., consisting of E. J. Pratt, T. E. Palmer, and E. McMeechan, all of the Southwest Missouri Electric Railway Co. is opening up a good lead prospect on a sub-lease of the Matthews & Wampler lease on the Four Hundred Prospecting Co.'s land, southeast of Duenweg.

H. C. Johnson, who recently took a lease on the Four Hundred Prospecting Co.'s lease on the Schifferdecker land, near Diamond, made the first turnin from that land last week amounting to 300 lb. lead. This is a very small amount, but in a short while the mine is likely to become a good producer.——Conklin & Ritter, owners of the Paxton mine on the Missouri Lead and Zinc Co.'s land last week cleaned up 100 tons of zinc ore. The ore is among the highest grade in the district. The mine was opened up some time ago in a peculiar way; it was thought it had been worked out and it was almost on the point of being abandoned when it was decided to sink a few feet on the hard ground at the bottom of the shaft. They only sank a few feet through the lime when they went into open ground again and also into what has seemed since a regular jack bin.

The Avondale and Dominion mines, owned by Messrs. Dodge & Patton, of Webb City, operating on the Aylor land at Prosperity, have produced $400,000 in three years. This ore came from a 50-ft. face of ore, which continues at least 25 ft. deeper with equal richness.

Calumet, Michigan.

Output of Copper in 1906.—Estimate of Profits.—Tendency to Consolidate.—Latest Rumors on the Subject.

In the year just ended the Lake Superior mines produced roughly 225,000,000 lb. copper. This is a slight gain over 1905, but the marketable supply will be less than in that year as Calumet & Hecla will presumably have no surplus for sale. If we assume an average price of 19 cents, the gross receipts amounted to $42,750,000, and if the cost be taken at 10 cents the net earnings would aggregate $20,250,000. The year has been marked by the entrance to the producing ranks of Victoria, Tecumseh, and Winona, and the retirement, temporarily, at least, of the Atlantic.

While the above figures make a very handsome total, 1906 will be noted not only for its large earnings, but for a new tendency that has now become quite general. This is to consolidate the smaller companies. Looked at in a broad way, it is rather remarkable that this was not begun before. Michigan is the only great camp which is distinguished by a large number of producing companies. Butte, with an output of 350,000,000 lb., is controlled almost entirely by the Amalgamated and its allied interests; at Bisbee, which has now reached an output of 150,000,000 lb., there are only three producing companies; at Cananea, Mexico, destined to become one of the great camps of the continent, there is only one company of importance, and so on around the circle.

As one studies the Michigan map he is at once impressed by the innumerable number of small properties with irregular outlines, one cutting into another and in many cases preventing the carrying of operations to depth. Probably only the Michigan law, which confines companies to the vertical limits of their properties, has delayed so long the amalgamation of the smaller concerns. Of course there has been innumerable swapping of 'forties' for mutual advantage, but until 1906 there was no movement toward a broader policy. Now it begins to look as if it would boil down to half a dozen large operators. The tape suggests the combination of all the mines on the Kearsarge lode to the north of Calumet & Hecla. This would include Centennial, Osceola, Wolverine, Allouez, Ahmeek, and Mohawk. The action of all these stocks indicates buying for control. To the south of Calumet, Quincy may be left as the sole survivor. The south range mines will very likely be divided between Calumet and Copper Range. The movement is not so pronounced in the Ontonagon county mines but here also there are rumors of acquirement by the larger interests.

Not only are the producing mines apparently to be combined, but the undeveloped mineral lands are being rapidly taken up simply as a matter of acreage. In the upper peninsula Keweenaw Copper and Calumet have already acquired enormous holdings When it is considered that several of the most valuable producers of today were for a long time considered worthless and only of late years have been earning money, it will be seen that the possibilities here are tremendous. Some may regret, for sentimental reasons, the passing of the old regime, but concentration of management is the order of the day and Michigan is simply falling into line.

Salt Lake, Utah.

New Smelter Site.—Developments at Tintic.—Another Smelter.—Ore Shipments.—Gold at Pelican Point.—Transfer of Ontario & Daly Mines.—Nevada-Douglas.—Local Stock Business.

The management of the Utah Consolidated Mining Co. has settled its own 'smoke' question by selecting a site for its proposed $1,000,000 smelting plant on the west side of the Oquirrh range of mountains and near the town of Tooele. A tunnel will be started at a point between one and two miles above the smelter site and run through the mountain 11,000 ft. to a connection with the orebodies of the Highland Boy mine, tapping the same about 1,000 ft. below the lower adit level. Pending a completion of the tunnel an aerial tramway will be built and operated over the mountain. The company will build several miles of railroad track to connect with the main lines of the Western Pacific and Los Angeles & Salt Lake railroads.

Important developments have been made on the 1,700-ft. level of the Lower Mammoth mine in the Tintic dist-

riet. The main shaft was sunk to this level recently and a drift run from the bottom to connect with the ore. The body shows a width of 20 ft. and the greater portion of it is rich enough to ship.——The officers of the Tintic Smelting Co. have selected a site for the smelter they purpose building. The plant will be conveniently reached from all the mines of the Tintic district and will only be a short distance from the main line of the Los Angeles & Salt Lake railroad.——Jesse Knight, of Provo, is said to have purchased a controlling interest in the Eureka-Swansea mines. The Yankee Consolidated and Beck Tunnel Consolidated companies have entered into an agreement establishing vertical lines as the boundary between their respective properties, thus avoiding any controversy in the future over apex rights.——The ore shipments from the Tintic mining district last week were not as heavy as usual owing partly to bad roads and disorganization due to the holidays. There were sent to the Salt Lake smelters, however, 119 carloads of ore, the contributing mines and their amounts being: Ajax, 2; Beck Tunnel, 8; Bullion Beck, 7; Carisa, 2; Centennial Eureka, 38; Eagle & Blue Bell, 9; Eureka Hill, 2; Grand Central, 3; Joe Bowers, 1; Mammoth, 14; May Day, 2; Paynter, 1; Scranton, 2; Swansea, 2; Tintic Iron, 4; Uncle Sam Con., 1; Victoria, 6; Yankee Con., 6 carloads.

Considerable interest has been aroused in some recent discoveries of low-grade gold ore on the west side of Utah lake, in Utah county, near what is known as Pelican Point. The character of the ore is similar to that at Mercur. A syndicate of Provo, Seattle, and Eastern parties has acquired a large group and organized the Pelican Point Mining & Development Co., with Judge W. N. Dussenbury, as president. The headquaters of the corporation is at Provo. It is claimed that sufficient development has been performed to warrant the construction of a cyanide mill.——The fuel famine at the Consolidated Mercur has been so much relieved that the management has started some of the roasters again. During December this portion of the plant was out of commission and only the oxidized ores received treatment.

An important deal affecting Park City mining property was affected in New York last week when the control of the Daly and Ontario, two of the oldest mines in that camp, passed to Jacob E. Bamberger, president of the Daly West Mining Co. It is believed that Mr. Bamberger will consolidate these mines. The Ontario has paid about $14,000,000 in dividends. Aside from its metal-mining property the Ontaria company owns the Weber coal mines at Coalville, about 15 miles from Park City, and also some valuable water rights and franchises, including the electric lighting and power system of Park City.

The management of the Nevada-Douglas copper mine at Yerington, Nevada, has placed a large order for mine equipment. Walter C. Orem of Salt Lake is manager. E. P. Jennings, a Salt Lake mining engineer, recently made an examination of this mine and reported that it contains 10,000,000 tons of available ore with an average copper content of 3½%. By treating 1,000 tons per day, Mr. Jennings states, the mine is capable of producing 24,000,000 lb. of metal annually at a cost in New York of not to exceed 8½ cents per pound. Mr. Jennings estimates that the cost of constructing 20 miles of railroad to connect with the tracks of the Southern Pacific system near Wabuska will be about $175,000; that a concentrating mill of 1,000 daily capacity can be built for $750,000 and a smelter of 500 tons daily capacity, for $500,000.

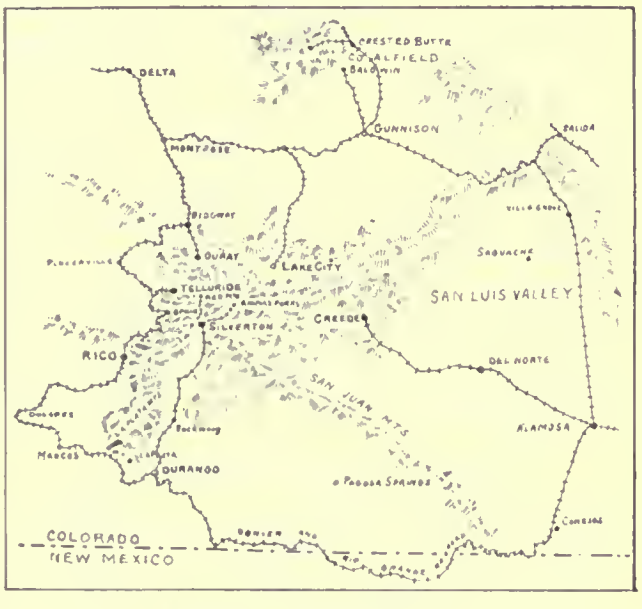
The total sales for the year 1906 on the Salt Lake Stock & Mining Exchange amounted to 14,555,391 shares, for which was paid the sum of $9,178,983.

Denver, Colorado.

Annual Statistics.—Fine Record for 1906.—Cripple Creek and Leadville Leading.—Excellent Dividend Showing.—Smelters do a Big Business.—Zinc Output of Leadville.—The Old Gold Districts.

Statistical data prepared for the year 1906 show that the mining industry of Colorado has had a remarkably successful year. Colorado's mines have paid $17,794,784 in dividends, while the lessees have netted about $5,000,000 during the year. The production of gold namely $26,895,517, is an increase over the three preceding years, and is only exceeded by the output during 1900-1902 inclusive. The total production of mineral for the past year, including gold, silver, lead, copper, zinc, and tungsten was $49,810,295—a record figure. The output of coal has increased steadily, reaching $18,500,000 during the past year, a gain of $3,000,000 over 1905.

The biggest gross production comes from Teller county, which is identified with Cripple Creek; this district pro-



Map of Southwestern Colorado.

duced $17,790,000 in gold. The second in rank is Lake county, where Leadville is situated; the gold production is estimated at $1,249,403; silver, $1,101,394; lead, $3,051,261; spelter, $1,511,758; and copper, $875,008, making a total of $13,884,324. Teller and Lake counties are responsible for three-fifths of the metal production of the State. The second gold-producing county is San Miguel, and then come Gilpin, Lake, and Ouray, ranking equally with a production of about $1,250,000. In silver, Leadville of course is easily first; Pitkin county, which contains Aspen, being second, with $1,367,118. No other county produced a million dollars in silver, although San Miguel came close to it. In dividends, Teller county is ahead, with a record of $6,313,000. Lake county is second, with $2,070,000.

The smelters and mills of Colorado did a big business, their total gross output being nearly $83,000,000, of which $33,681,223 represents the business done by the American Smelting & Refining Co., and $25,054,929 the gold received at the United States Mint at Denver. It is evident that the mint and the smelters received a good deal of ore from the surrounding mining regions outside of Colorado.

At Cripple Creek there was much activity. Five mills have recently been completed—four cyanide plants, and one combination of chlorination and cyanide—which will swell the production for 1907. Better rates have

been secured from the mill and smelter trust, and from the Golden Cycle Milling Co. The new drainage adit is to be started at once, and is expected to reach the El Paso shaft in two years, and the Vindicator in three years more.

In the San Juan region, comprising the southwestern portion of Colorado, the yield of gold aggregated $4,952,000; this is a slight decline from 1905, which is partly explained by the enforced idleness of the Silver Lake mill at Silverton and the Camp Bird plant at Ouray, while another important factor was a general shortage of labor, skilled and unskilled, throughout the year. In Lake county, the production of zinc is of growing importance; the output of this base metal exceeded that of the precious metals in value. It will be remembered that Leadville started as a gold camp, then became famous as a producer of silver and lead, and now zinc has become the most important product. The erection of custom mills for the treatment of low-grade zinc ores was an important feature of the last year.

The pioneer gold belt, embracing the counties of Boulder, Gilpin, and Clear Creek, is doing fairly well. Some of the mines in these districts have been in continuous operation since 1859. The following gross outputs and dividends are recorded :

County.	Gross Output.	Dividends.
Boulder	$ 581,293	$150,000
Gilpin	1,552,327	425,000
Clear Creek	1,166,730	780,000

In Boulder county the mining of tungsten ore has been a feature, the output being valued at $325,000, which is not included in the above total. Also fluorspar, to the value of $28,000, was shipped to the steel works at Pueblo. In upper Clear Creek there has been much activity, several new mines and mills having been started, so that the outlook is good.

Cripple Creek, Colorado.

Annual Report of Stratton's Independence.—Interesting Figures.—Output from the Acacia.—Standard Leasing Co.—Strike in the Granite.—United Mines Co.—Litigation with the Londonderry.

The annual report of Stratton's Independence, Ltd., for the year ending June 30, 1906, is to hand and shows the amount of ore shipped to have been 32,499 tons, with a gross value of $1,245,124. The division of this amount between the lessees and the company, together with the charges for freight and treatment, shows:

	Gross Value.	Freight and Treatment.	Net Value.
Lessees	$1,214,942.20	$320,233.27	$924,708.93
Company	181.96	164.83	17.13

Of the net value of their ore the lessees received $583,739 as their proportion, the difference of $352,969 being the total of the royalties and percentages of profits retained by the company. The profit for the year, including the London expenses, was $228,128. During the financial year three dividends of sixpence per share were paid, bringing the total of dividends paid since the incorporation of the company up to nearly £1,000,000. The tonnage shipped was about 50% less than that of the previous year, the grade remaining practically the same. The cost of freight and treatment is comparatively high owing to the lack of a contract with the A. S. & R. Co., the latter having charged the open rate, which made approximately an increase of $1.25 per ton. From the supplementary report of the general manager, Chas. M. Becker, it is noted that the matter of erecting a mill for the treatment of the low-grade ore in the mine and on the dump should be delayed no longer. At the close of the fiscal year there were 40 sets of lessees in the mine.

S. N. Simmons, operating a lease on the Pharmacist property on Bull hill, has obtained a lease on the Acacia Co.'s ground adjoining, after having stoped up to the side line. The lease has always been worked through the Fitch shaft of the Acacia, having no connection with the Pharmacist shaft, and several shipments of good ore have been made.——A gold brick valued at $6,000 has been shipped from the Anaconda mill to the Mint at Denver. This was the result of the clean-up after the treatment of 500 to 600 tons of dump from the Lexington property. Low-grade ore from the second level of the Lexington will now be treated for the Union Leasing Co.——The enlargement of the ore-house of the Standard Leasing Co. operating the South Burns claim of the Acacia Co. on Bull hill, is nearing completion ; the ore-house will hold about 300 tons and will contain six tables, accommodating 12 ore-sorters. The ore-body being mined at a depth of 800 ft. is an extension of that of the Findley and Shurtloff and regular shipments of good grade are being made right along. The shaft has been sunk 60 ft. below the 800-ft. level, and a drift is being commenced for the exploitation of the orebody to the north.

A good strike has been made in a raise from the 100-ft. level of the No. 1 shaft of the Granite Gold Mining Co. within the limits of the city of Victor. Childs & Fehringer have this part of the Granite property under lease. The streak averages about 5 in. wide, the stoping width being 2 to 2½ ft. Three shipments have been made, returns around $30 being obtained. —— The Grace Gold Mining Co. has installed a six-drill compressor on its Squaw mountain property. Two drills will at once be put to work on development and air will be supplied for a like purpose to the adjoining properties — Home Run, Santa Rita, and the Nevada King tunnel.

A circular letter has been issued to the shareholders of the United Gold Mines Co. by the general manager, H. McGarry, giving a review of the properties acquired a few months ago by the Golden Cycle Co. from the Woods Investment Co. These include the Wild Horse, Deadwood, Requa, Damon, May B., and W. P. H. It is stated that the reserves were practically exhausted at the time of the transfer, and that leasing was going on in a half-hearted manner. Since that time some 20 new leases have been granted, and a good deal of systematic development is being done, results from which are expected during the ensuing year. With regard to the financial condition of the company, the following figures are given: "The gross receipts of ore sales from the properties for the first eight months of 1906, before we took charge, were $115,974; the amount of royalties received from this by the company were $34,302. The gross receipts for the remaining four months (December not all in) were about $34,323, the royalties received from this about $10,798." A suit is pending between this company and the Londonderry in the Supreme Court of Colorado for the sum of $67,000, which was awarded to the U. G. M. Co. in the District Court. Since the incorporation of the company eight dividends of one cent and four of half a cent have been paid the shareholders, the last being distributed in March, 1905.

A special hearing has been granted in the United States District Court, in the suit of the Vindicator Co., of Cripple Creek, against the Frankfort Marine and Akron State life insurance companies, in the case of the score of men killed there in a dynamite explosion three years ago. —— J. M. Parfet, operating on the Lucky Corner claim on Gold Hill, reports a strike at a depth of 40 ft. The vein shows a width of three feet and is said to contain five ounces in gold. Kansas City parties have recently purchased the Delmonico claim, and, since unwatering the shaft, have been driving east on the 400-ft. level to cut the extension of the orebody which shows on the surface.

Mining Summary.

ALASKA.

The Hadley copper mines, owned by the Alaska Mines Securities Co., consist of 12 claims comprising 198 acres extending from tidewater to an elevation of 1,050 ft., the ore being shipped from mine to smelter by an aerial tramway. Active developments began in June, 1905, and shipments of ore to smelter began four months later. The mine itself has paid all expenses of development and equipment, in addition to which it has recently paid three dividends amounting to $90,000. The net proceeds of the ore after deducting freight and treatment charges are $10 per ton. The ores contain 32% iron, 31% insoluble matter, 8½% sulphur, 7% lime, and are free from arsenic and antimony, making them practically self-fluxing and desirable for smelting. ——The Uncle Sam copper mine is located three miles from the Hadley group and extends from tidewater at an elevation of 1,600 ft. A vein of copper ore, containing gold and silver, 40 ft. wide and extending 1,200 ft., has already been exposed. The property is well equipped with buildings, wharf, etc., and a tramway of 1,150 ft. conveys ore direct from mine to wharf. Shipments made to smelter are giving returns of $22 per ton. Additional equipment is now being erected and the output will be greatly increased.

The traffic manager of the White Pass & Yukon railroad reports that 20 dredges will be shipped to the Yukon district this spring. The Forty-Mile region is coming to the front, seven dredges having been ordered. On the Stewart and Upper Stewart there are already two dredges, and the prospects in this district are bright for a good production. ——Robert A. Kinzie, superintendent of the Alaska-Treadwell, has just returned from Seattle, where he has been arranging for a supply of coal. He reports that 7,000 tons are on the way and 40,000 tons more are to be shipped at once, which relieves the necessity of even a temporary shutdown of the mines.

ARIZONA.

GILA COUNTY.

The most important deal yet consummated in the Globe district involves 29 claims situated within six miles of Globe, and a consideration aggregating $300,000. The properties concerned in the transaction are the Oates-Newman group of 16 claims, which have been bonded from J. B. Newman, Philip Oates, Joseph Fauli, and J. P. Fauli, and a group of five claims adjoining, owned by W. D. Fisk and J. W. Bandhauer and associates. Negotiations for the deal were under way as far back as last October, when options on the various claims desired were obtained. A force of men has been put to work on initial development, which will be prosecuted with vigor and on a large scale. The identity of the purchasers has not yet been made public, F. C. Alsdorf, recently of Clifton, acting as agent in the deal in connection with the new company's attorney, F. J. Elliott, and as manager for the mines. The first work upon the properties will be the development of the Captain claim of the Oates-Newman group, and of the Red Spring claim, formerly owned by Patterson & Wogg. Sinking for a three-compartment shaft has already begun on the Captain, and a similar shaft will be sunk upon the Red Spring. The Captain shaft will be in ore from grass roots. Three shifts will be put to work on both properties immediately, and hoists have already been ordered. The ground is contiguous and similar in formation to that upon which the Inspiration is situated. Engineers declare it the most heavily mineralized portion of the Globe district.——The option upon the pooled stock commonly known as the Phelps-Dodge interest in the Old Dominion mine has not been exercised, and Phelps, Dodge & Co. will retain their heavy interest in this property. The turning down of this deal was based upon the opinion of engineers who examined the property for the prospective purchasers and reported that they failed to find sufficient ore to warrant the purchase of the stock at the price, which was slightly under $60 per share. Messrs. Lee, Higginson & Co. acted as agents for those to whom the option was given, and whose names have not been disclosed.

MOHAVE COUNTY.

(Special Correspondence).—Henry Lorin, ex-sheriff of Mohave county, has made the first payment on the purchase of a group of mines owned by Jack Flynn and Bob Ferguson. The mines are situated south of the New London and have been developed to some extent, making a good showing of lead ore.—— Schee Brothers, of Santa Monica, are working six men in the Pinkham mine at Chloride, and shipping about a carload of ore every two days to the smelter at Humboldt. The ore is of desirable quality and brings good returns. The mine is paying its way and carrying some dead work.—— The grade for the Oro Plata mill has been completed, and it is expected the machinery will arrive in a few days. The Oro Plata is one of the best gold and silver mines in Wallapai district, and produces lead carbonate.—— J. D. Jordan is preparing the ground at the McKesson mine, south of Kingman, for the installation of hoisting machinery. The machinery is expected at the mine by Jan. 15.——Mrs. Martha Osborn, of Kingman, has received news of a strike in a mining claim at Cerbat, in which she is a co-owner. Specimens of the ore sent her are filled with gold.—— The Tennessee mine, at Chloride, is shipping ore to the smelter at Humboldt. The ore is rich in lead and carries gold and silver.——Last week the sheriff brought to Kingman from the Gold Road mine, at Acme, in San Francisco district, a bar of gold bullion worth $48,000. This is the second largest bar produced by the Gold Road Co., the other one being valued at $52,000. The ore now going through the mill is far richer than any treated during the past year.—— Foster S. Dennis has taken charge of the mill at the Berkeley mine, in Blue Mountain district, which is now in course of construction. Mr. Dennis is the owner of a one-half interest in the property, and will concentrate the ore on the dump and in the old stopes.

Phœnix, Jan. 4.

CALIFORNIA.

AMADOR COUNTY.

A large block of stock of the Argonaut Mining Co. will be transferred by sale from W. F. Detert, the principal stockholder, to a company of capitalists. It was reported that the sale was made, when N. Matthews of New York and his attorney, A. C. Ormsby, arrived in Jackson to inspect the Argonaut property. In order to secure a controlling interest in the mine the prospective buyers must obtain at least 101,000 shares of stock, the market value of which at $4.75 per share, would amount to $479,750. The Argonaut Mining Co. has purchased from W. F. Detert a piece of mineral property adjoining the company's possessions and known as the Hoffman ranch.

NEVADA COUNTY.

Otto Woehler has bonded nearly 8,000 acres of highly mineralized land at Spenceville, with the intention of developing a number of abandoned copper claims in that district. Specimen ore brought to Grass Valley from the lodes traversing the bonded property has given assays running as high as 30% copper and some gold. It is believed that the lode of the Dairy Farm copper mine runs through Spenceville.——As a result of a conference between committees from the Miners' Union and the executive committee of the Mine Operators' Association, it is believed that the end of the strike is in sight and that the men will be working in a few days. A compromise will probably be reached during the week on the basis of 9 hours underground, the miners to put in 7½ hours of actual work. The conference was friendly and a conciliatory spirit was shown by both sides, the miners, however, being firm in their demands.

The Banner mine, near Nevada City, is out of fuel, and only the pumps are running, wood being burned under the boilers.—— The miners at the Murchie and Mountaineer mines are now working eight hours. It is thought that soon every mine in the district will be running on the eight-hour basis.

The strike is still on at Grass Valley, and the Conlan is the only mine at work in the district, about 12 men being employed at this property, while 650 men are idle in the region. The Kenosha, California, and Jenny Lind mines were reported to have acceeded to the demands of the Miners' Union, but they are still closed. The Mine Oper-

ators' Association has made a public statement to the effect that they feel they were unfairly treated by the men when they walked out without giving due notice of their demands, and that the owners think the Union should have communicated their demands, and allowed a reasonable length of time for the operators to accept or reject the proposition. The Union demands seven and one-half hours' actual work, and offers to either go down or come up on company time, and eat on their own time at noon, claiming that this is the system in use in most of the important camps throughout the West. On the question of demanding an increase of wages for the carmen and shovelers, 451 votes were cast in favor of such a demand, but the vote of 114 against the proposition defeated it by the narrow margin of two votes, since a three-fouths vote is required to decide questions of this kind.

(Special Correspondence).—The recent heavy snow-storms have retarded mining, but everybody is well pleased, as an abundance of water for all purposes is assured for the entire year. A number of new properties are to be opened as soon as the weather clears. The Delhi mine, at Columbia hill, which has already paid $600,000 in dividends, recently opened exceedingly rich ore. One hundred tons were milled yielding $50 per ton. The owners have expended over $45,000 during the last two years in surface improvements and dead work.——The North Star recently declared a dividend of 40 cents per share, being $100,000. A company headed by Frank A. Garbutt, of Los Angeles, recently purchased several claims from John H. Keller of Graniteville. It is planned to drive a tunnel 1,500 ft. long to obtain 800 ft. of back. The vein in places has a width of 30 ft., averaging $5 per ton. George Shelby has cut a shoot of ore in his mine near Nevada City, a mill test yielding $40 per ton.

Nevada City, Jan. 7.

PLACER COUNTY.

The Northern California Mines Co., a corporation composed of Pittsburg men, owning the old Osborn mine near Westville, has completed a tunnel 1,400 ft. long, and drifts have been run each way on the vein from the end of this tunnel. This work has proved that the lode averages six feet wide and that the ore is of a good milling grade. A force of 25 men is at work in the mine, and will continue throughout the winter. The Joshua Hendy Co. is building a 40-stamp mill on the ground, which will be run by electric power generated on the Middle Fork of the American river. It is the plan of the company to increase the mill to 100 stamps within a year.

COLORADO.

BOULDER COUNTY.

The old workings of the Golden Age mine, near Jamestown, are being cleaned out. I. V. Sybrant is superintendent. The ore now on the dump and blocked out in the workings will be treated at Springdale. The tunnel of the U. S. Gold Corporation on Sugar Loaf Mtn. is in 1,200 ft. ——The Annuity Co. is erecting a new mill at the Dolly Varden mine near Sunset.——The Denver Tunnel Co. will resume work on its property at once.

CLEAR CREEK COUNTY.

The new schedule of rates on lead, zinc, and copper ores is expected to affect favorably the mining industry in this county. The average advance in the price of lead ore will vary from $2.50 to $5 per ton, according to the grade of the ore, while there is an increase over present prices of zinc, buyers giving a premium of $3.20 per ton on all ores carrying over 40% zinc. The advance in copper rates is from $1 to $2 per unit, according to the value of the ore. This new schedule is expected to have the effect of opening some of low-grade mines that have been idle for years.

OURAY COUNTY.

One of the most important strikes made recently in the Ouray district occurred in the Jonathan, just north of Ouray and almost within the city limits. The find was made by the lessees, John Wall and Chas. Swope, who are said to have taken out $60,000 from the pocket. The ore runs in car lots from $1,000 to $2,000 per ton. The discovery was made in the lower level, and only a short distance from where the present lessees commenced work.

SUMMIT COUNTY.

(Special Correspondence).—Owing to increased production, Summit county is beginning to receive more attention, and with its mines of gold, silver, lead, zinc, iron, copper, and bismuth, its water supply, its abundance of timber, and other natural advantages, it is now attracting the notice of mining men, as well as of the Eastern capitalists looking for investment. The consolidation of holdings and interests is an important feature of the past year. The Jessie Gold Mines Co. has been organized by James T. Hogan, after working the Jessie mines and mill on a bond and lease for over a year. The Jessie, Diana, and Florence groups, which comprise about 500 acres, are consolidated in this organization, which is incorporated for $1,500,000 in shares of $1 each. The property has been favorably reported on by David H. Lawrance, and the ores tested by Mr. Knappe cyanide expert, also of Denver. It is the intention of the new company to install a mill of 400 or 500 tons daily capacity, with a subsidiary cyanide plant for treating the tailing. ——The Colorado Consolidated Dredging Co. has taken over the placer ground of the old American Gold Dredging Co. on the Swan and Blue rivers. This company is going to commence the construction of new dredges, and with the two old ones put in order and brought up to date with modern improvements, it will have a plant capable of handling several thousand yards of gravel per day.——The Wellington Mines Co. is a consolidation of the Wellington, Oro, and Orthodox properties. Last week it was reported that a new vein of gold-bearing carbonate ore had been discovered. In prospecting the surface the superintendent, Peter L. Cummings, uncovered this vein 150 ft. from the point of original discovery. It varies in width from two to four feet and contains a streak six to ten inches wide that is well charged with gold. The cross-cut being driven to intercept this vein from the adit is entering a mineralized zone. Development of the zinc-lead shoots has been proceeding steadily and plenty of ore is ready for shipment. Finishing touches are being given to the new track, ore bins, chutes, and automatic dumper, which are to make easy the intended shipment of three carloads per day.

Breckenridge, Colo., Jan. 4.

IDAHO.

ADA COUNTY.

(Special Correspondence).—The property of the Big Giant Gold Mining Co., 10 miles northeast from Boise, has 4,450 ft. of development work, the greater part of which was accomplished within 1906. This work is said to have exposed orebodies of sufficient size and value to justify the erection of a 200-ton mill, and preliminary steps are being taken for the construction of such a plant. The ores consist of quartz, carrying free gold. Orville E. Jackson, of Boise, president of the company, hopes to have the mill in operation by August.

Boise City, Jan. 7.

BOISE COUNTY.

The Nellie mine, owned by the American Exploration Co., situated on the Payette river, near Horseshoe Bend, has driven 1,600 ft. on a cross-cut adit, which is expected soon to cut the vein at a depth of 850 ft. The lode for which they have been driving has been well opened to considerable depth on the Kentuck, which end-lines with the Nellie. Work has been in progress upon the Nellie for two years, and M. E. Hopkins, manager, states that the company has expended $45,000 in equipment and development.——The Kentuck mine, belonging to the United Mines Co., is having thorough tests made with a view to improving its milling method, which hitherto has been concentration.

The Golden Treasure Placer Co. contemplates installing hydraulic elevators next season for work on Payette river, 15 miles above Garden Valley.—The Gold Coin Co. has installed a 30-ton mill at their mine near Idaho City. It is equipped for amalgamating and concentrating. The mine has been opened by an incline shaft 164 ft. on the dip of the vein, with some driving on various levels. The vein has an average width of four feet, the ore being a free-milling quartz with considerable sulphide. J. H. Emery of Idaho City is president of the company and superintendent of the mine.

NEVADA.

ESMERALDA COUNTY.

(Special Correspondence).—On the Mohawk, the Hays Monnette lease, which will have terminated when this letter appears in print, is taking out ore at the rate of $30,000 per day, and other leases on the same mine are taking out their quota. Properties near at hand and at the most remote corners of the district are working feverishly. Three or four leases on the Kewanas are in high-grade ore, which is being sacked preparatory to shipment. Sacks of rich ore are piled on the dumps of the leases on the Night Hawk claim, and the Grandma is the scene of much activity. On the August claim, several lessees are busy, and two or three of the workings are in ore. On the Simmerone claim, adjoining the Blue Bull, the Simmerone Mining & Leasing Co. has been formed, and is sinking a shaft to catch the orebodies that have been opened on that ground. At present the shaft has reached a depth of 90 ft., and three veins have been cut, all carrying good milling ore. It is the intention of the company to sink to 200 ft. before cross-cutting or driving. A head-frame has been erected above the shaft, and a gasoline hoist will soon be on the ground. The Simmerone claim will be remembered as one of the leading strikes of the camp in the early days, when rich ore was carried across the desert to Tonopah under armed guards. A high fence was built around the claim to prevent stealing. An important deal was recently consummated, by which the Homer Wilson Trust Co. came into possession of the Crestone and Whale claims, a short distance east of the Dixie, and adjoining the Nightingale group. Several strong veins traverse the property, from which good assays have been obtained.

This part of the Goldfield district, north to Diamondfield, is the scene of great activity, and nearly as many men are working on the different properties as on the producers nearer town. On the Goldfield Somerset property, several men are exploring a 12-ft. vein recently uncovered, that returns $15 in gold from the grass roots. On the Bonanza claim of the Goldfield Madonna, a vein about 5 ft. wide was encountered at a depth of 40 ft. that assays well. A hoist is being erected on this property, and work will be continued systematically. On the Aurora claim, a short distance south of Diamondfield, the workings are in high-grade milling ore. Several veins have been opened on this property. The same may be said of the Freedom claim, adjoining the Aurora. Several strong veins traverse this property, and in sinking the company shaft to its present depth of 100 ft., three or four streaks were crossed, all carrying pay-ore. It is the intention of the United Tonopah & Goldfield Mines Co., which own the Freedom claim, to cross-cut to these various veins at depth. In and around Diamondfield, development work is being carried on with feverish haste to open the orebodies already disclosed on the Daisy, Jumbo Extension, Great Bend, Quartzite, Black Butte, and others. All these prospects are in high-grade ore.

Word has been received from the Selby smelter, near San Francisco, that 50 tons of ore shipped from the Hays-Monnette lease on the Mohawk this week returned $700,000. The Frances-Mohawk shipped 25 tons that returned $250,000. This is an unprecedented record.

A letter from Wallace MacGregor, consulting engineer of the Nevada Condors, of Fairview, and the Joe Wonder Mining Co., of Wonder, states that mining operations in these two camps are assuming large proportions, and many companies have found ore since his last visit to the district a month ago. The showing on the Nevada Condors is exceedingly encouraging. In the present workings the vein has widened, and the character of ore has improved. All ore taken from the Nevada Condors is of good milling value, while some of it is high-grade stuff. This prospect lies in the heart of the rich Fairview district, and from present indications should soon become an active producer.

Every stage into Wonder is crowded to the guards. People are entering the new fields from all parts of the State, and it is predicted that in three months Wonder will have a population equal to any camp in Nevada, outside of Goldfield and Tonopah.

New strikes are reported daily, and important mining deals involving large sums of money are being made. Big prices are being paid for favorably located claims, and the pioneers of the district are assured of having their camp thoroughly developed. No less than 40 properties are in high-grade ore. The Nevada Wonder is the most prominent. This company is sacking $1,000 ore preparatory to shipment. The Jack Pot is another producer of high-grade ore. The June Wonder, Daisy Wonder, Joe Wonder, Lucky Strike, and many others are looking well.

Goldfield, Jan. 8.

Later advices state that on January 9 the Miners' Union held a meeting to consider the proposition of the mine operators, which named $5 per day for miners and skilled help, and $4.50 for laborers. The total number of votes cast was about 1,700, or one-half of the total membership of the Union. It is understood that the majority of voters favored the proposition, and that the strike is over, in which case all the mines will open within a few days. In view of this change, the stock market is showing increased activity.

LINCOLN COUNTY.

(Special Correspondence).—In driving on the vein on the 150-ft. level of the Searchlight-Treasurer mine, a rich streak of ore was encountered; it is similar to that found on the New Year's Gift mine of the Duplex Co., not over 1,000 ft. distant. The strike is one of the most important yet made, and the mine being right in town, the owners have purchased the mineral rights under the townsite itself.—— Work has been resumed on the property of the Searchlight-Belle Co. Several strikes were made recently in the immediate vicinity of this property on the Colorado, Wyoming-Searchlight, Santa Barbara-Searchlight, and Golden Rod.

Searchlight, Jan. 8.

BRITISH COLUMBIA.

The Rossland mines have produced well during the past year, and some important strikes have been made. The total output for 1906 was 277,361 tons, with an estimated value of $3,338,332. This is a lower tonnage and value than the preceding year, in fact it is the lowest since 1899, but the camp is in good shape and a prosperous new year is expected.

Le Roi mine leads with a record of 126,396 tons, closely followed by the Centre Star, with 114,500 tons. Le Roi No. 2 has shipped 21,000 tons and milled 10,500, and the White Bear milled 1,350 and shipped 570 tons. The other producers were the Jumbo, Mabel, Crown Point, and O. K. mines.—— The Centre Star consolidation includes the War Eagle, Centre Star, Pilgrim, Mugwump, and Red Mountain, and the recently purchased Idaho and Iron Mask. Much diamond-drilling has been done from the lower levels, and the vein has been proved to a depth of over 1,200 ft. The Centre Star main shaft is down 2,000 ft. W. H. Aldridge is general manager for the company, M. E. Purcell is the superintendent, and R. H. Stewart the chief engineer.——Le Roi has a winze down 400 ft. below the 1,350 level, and the main five-compartment shaft is down to the 1,460 level, and is being extended by contract work. There are 325 men employed.——Le Roi No. 2 has done 3,053 ft. of development work during the year, and 5,091 ft. of diamond-drilling. The ore shipments, amounting to 21,000 tons, have averaged about $24 gross value, and the 10,500 tons milled at the concentrator ran $3.50 per ton, and produced concentrate worth about $30 per ton.—— The White Bear has done 350 ft. of drifting and 150 ft. of cross-cutting during the year, with 500 ft. of diamond-drilling. Much of the work has been done on the 1,000-ft. level.

The Trail works of the Consolidated Co. now has a capacity of from 1,500 to 1,800 tons of ore per day. A new copper-blast furnace has been added, making five now in operation. The lead furnaces have a capacity equal to 75 tons of metallic lead per day. The Huntington Heberlein process of roasting has proved successful, and six more converters have been added. The capacity of the refinery has been increased to 75 tons per day. The number of men employed has averaged 550, the copper furnaces have treated 240,000 tons, and the lead furnaces 17,500 tons during the past year, although they were closed down for several months for repairs. The Northport smelter has a capacity of 1,200 tons daily, and has recently resumed operations after a long shut-down.

Personal.

WM. M. BREWER is at Los Angeles.

W. P. HAMMON is on his way to New York.

JAMES W. NEILL was in San Francisco during the week.

ROBERT T. HILL is examining mines in Beaver county, Utah.

THEODORE DWIGHT has returned to New York from Mexico.

WHEELER S. BISHOP, lately in Oregon, has gone to El Oro, Mexico.

OLIVER P. POSEY, of Los Angeles, has been to San Francisco on a visit.

THOMAS EDWARDS has been visiting the mines of Kalgoorlie, Western Australia.

ALEXANDER HILL & STEWART have moved their offices to 4 Broad St. Place, London.

JOHN C. GARVIN is the new superintendent of the Tonopah-Rambler mine, in Nevada.

SCOTT TURNER has become assistant to the editor of the MINING AND SCIENTIFIC PRESS.

W. A. SWART has been elected president of the Western Association of Technical Chemists.

JOHN A. REID, of Stockton, Cal., has been examining copper mines at Yerington, Nevada.

GEO. W. BOGGS, of Baker City, Ore., will spend his time at Tuscarora and Goldfield, Nev., this year.

FRANK H. PROBERT visited San Francisco on his way to examine mines near Greenwater, California.

H. W. EDWARDS and A. B. BRYANT have formed a partnership, with offices at Silver City, N. M., and at Denver.

A. W. MCCUNE has resigned as president of the Cerro de Pasco Mining Co. and will return to Salt Lake City from Peru.

F. H. MINARD, who lately returned to Denver from Central America, is now examining mines in Arizona and Mexico

JOHN D. IRVING has been appointed professor of economic geology at Yale University. He is the editor of *Economic Geology*.

THOMAS T. READ has been placed in charge of the Department of Mining and Metallurgy in Colorado College, at Colorado Springs.

THOS. C. BURKE, of the Canyon Creek Mining Co., operating near Baker City, Ore., attended the inauguration of his brother as Governor of North Dakota, on January 8.

FRANK ROBBINS has taken over the management of the property of the Pacific Nitrate Syndicate in Death Valley. He will continue to make Los Angeles his headquarters but will divide his time between his consulting practice and the administration of the company mentioned.

THEODORE J. HOOVER has just completed an examination of the ancient lead-silver mines in the Calbeck Fells, Cumberland, in the north of England. These mines were first worked in 1050 and there was at one time a mint at Carlisle, where the silver, obtained from the mines near by, was coined.

Publications Received.

From the U. S. GEOLOGICAL SURVEY: 'The Yukon-Tanana Region, Alaska', a description of Circle Quadrangle, by L. M. Prindle. Being Bulletin No. 295, with several useful maps

UNITED STATES GEOLOGICAL SURVEY. I. Bald Mountain-Dayton Folio, Wyoming. 2. 'Geology and Ore Deposits of the Cripple Creek District, Colorado,' by Waldemar Lindgren and Frederick Leslie Ransome, being Professional Paper No. 54. This is a monograph of 500 pages, giving a summary of the previous reports on Cripple Creek, together with much new material. It is handsomely illustrated and represents the sort of work in the doing of which the Survey has no equal.

Mineral Output of British Columbia in 1906.

To the editor of the *British Columbia Mining Record*, we are indebted for the following statistical data, covering the mineral output of the Province in 1906:

Gold, placer	46,000 oz	$920,000
" lode	250,000 "	5,150,000
Total	296,000 oz.	$6,070,000
Silver	3,470,000 @ 63.5 cents	2,203,000
Copper	45,000,000 lb. @ 19.3 "	8,685,000
Lead	53,000,000 lb. @ 5.08 "	2,693,000
Zinc (approximated)		50.000
Total		$19,701,000
Coal	1,530,000 tons of 2,240 lb. @ $3	$4,590,000
Coke	210,000 " " " " @ $5	1,050,000
Miscellaneous, including building materials		1,000,000
Total non-metalliferous		$6,640,000
Total value of mineral production		$26,341,000

Dividends.

ON January 4, the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 112 of $180,000. This makes the total amount of dividends paid to date $8,046,000.

Latest Market Reports.

PRINCIPAL QUOTATIONS FOR MINES.

San Francisco and Oakland, January 10.

Argonaut	$4.80	Furnace Creek	$5.50
Con. Virginia	1.20	Savage	0.90
Mexican	1.03	Sierra Nevada	0.73
Ophir	3.03	Yellow Jacket	1.28
Belmont	5.37	Montana	3.95
Jim Butler	1.30	Mohawk	16.75
Jumbo	4.25	Red Top	4.25

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE work done by lessees is applicable to the annual assessment work required to be done on mining claims.

THE by-products obtained by the London, Gas, Light & Coke Co. are said to be worth $8.16 per 2,240 lb. of coal treated.

EACH 30 lb. of water evaporated into steam of 70 lb. pressure constitute one boiler horse-power; therefore when 15 lb. coal are consumed per hour on each square foot of grate, and each pound of fuel evaporates 7 lb. of water, 2½ h.p. is being produced per square foot of grate.

THERE is no doubt many abandoned mines would be working today if a competent engineer had been consulted with regard to the most suitable machinery required, instead of the matter being left in the hands of a superintendent who knew absolutely nothing of engineering principles.

IN building foundations the main objects in view are: (1) To form an unyielding bed for the support of the machinery. (2) To absorb vibration. (3) To resist the pull when power is transmitted beyond the base of the engine, as is the case in pumping, winding, and driving by ropes and belts.

THE available power of a waterfall is estimated by two factors, weight and fall, multiplied together; so the electric current is measured by volts multiplied by amperes, the resulting figures being termed watts. The watt is therefore a measure of electric power, and 746 of them are equal to an indicated horse-power.

WHEN temporary arrangements are being constructed around a new shaft, it is well to employ some foresight with regard to the permanent plant. The temporary gear can be fixed to one side, thus making it an easy matter to build the permanent works around the temporary without having to suspend operations in the shaft.

IN PRODUCING heat for power purposes, combustion proceeds at a medium pace and the oxygen is caused to combine with fuels which are valuable as heat producers in proportion to the hydrogen and carbon they contain. Hydrogen is three to four times as powerful an agent as carbon, hence the value of hydro-carbons, or mineral oils, as heat producers.

THE Land Department has held that the pendency of an adverse suit excuses for the time being the performance of annual labor. The Courts have not as yet passed upon the question. The ruling of the Land Department may be upheld as between the litigation parties, but there might be danger from re-location by outside parties disconnected with the litigation. It would be prudent to perform the work, or at least make a *bona fide* attempt to perform it. If the attempt is frustrated by acts, or threatened acts of violence, performance would be excused.

ONE horse-power is constantly lost in 152 ft. of naked 2-in. pipe, in 86 ft. of 4-in. pipe, and in 53 ft. of 6-in. pipe. When these pipes are covered with two inches of non-conducting composition, it requires over 1,150 ft. of 2-in. pipe to lose a horse-power, 750 ft. of 4 in., and 500 ft. of 6-in. pipe. Steam, therefore, needs as careful insulation as electricity. It is not a suitable means for power transmission to a distance, but should be used as near as possible to the boiler, the pipes and passages being kept short, as some loss is inevitable, no matter how well clothed they may be.

THE duty of the boiler is to transmit heat to the water within. This transmission is effected more quickly through thin walls than through thick, hence the quick steaming of those boilers whose tubes are thin and small in diameter. Heat is transmitted to the water in actual contact with the fire-tubes, but water itself is a poor conductor and does not readily disseminate the heat it receives; thus the heating of the contents of the boiler is effected largely by circulation, or movement of heated water upward and colder water downward. Boilers with slow circulation are slow heat transmitters and slow steam producers. A boiler evaporating 9¾ lb. water per pound of coal is utilizing about 75% of the heat produced, while many triple-expansion engines yield an indicated horse-power on from 12 to 20 lb. evaporated water per hour.

STEAM is defined as "an elastic invisible gas, generated from water by the application of heat." Water at sea-level boils at 212° F., and cannot be made hotter in an open vessel at that level; in a closed vessel, however, the temperature of the water varies with the steam pressure. There is a great difference between the heat required to boil water and that necessary to turn it into steam, no less than 966° F. being used in the change of form which the water undergoes, this amount being known as the latent heat of steam. But for this fact the change would be instantaneous and the whole of the water pass away as steam directly boiling point was reached; this is not the case, the change is gradual, and in accordance with the heat added. The heat required to evaporate one pound of water is sufficient to melt 13 lb. of gold.

A DYNAMO in its simplest form consists of a pair of magnets, and a number of conductors which cut or interrupt the lines of attraction between these magnets. In practice, the conductors would be bound together into a revolving armature, while the magnets are wound with wire to increase their attractive power. The current in the armature is collected by brushes, and may be of two different kinds. In the course of every revolution each conductor will cut the field between the magnets in two opposite directions, upward and downward. If the current generated in each direction is collected separately, the result is an alternating current. On the other hand, by collecting the current through a commutator formed of insulated bars, the brushes can be arranged to take up current in one direction only, and be insulated or out of gear when the conductor is moving in the opposite direction; the result in this case is a continuous or direct current.

A MINING CONCESSION in the Federated Malay States gives rights to the extraction of any metal or mineral found on or under the surface of the ground, and to install the necessary machinery for preparing the mineral for the market; the use of the needed land on which to erect houses for the miners, workshops, etc., and also of agricultural land for the cultivation of vegetables and plants necessary for feeding coolies; the exclusive use within the limits of the concession of all the products of the soil such as wood for building and for fuel, rattan, etc., provided same be used for the needs of the concession. All concessions must be thoroughly developed within six months after their grant and titles are valid for 25 years. It is thus impossible to retain a concession without working it, and the restriction is made with the sole object of preventing mining-land speculation.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Standardization of Screens.

The Editor:

Sir—I am much interested in your effort to make people describe screens by the size of the hole instead of by the mesh. The use of meshes is a most trying and misleading method of description that could possibly be imagined. For example, referring to Mr. Argall's convenient table of Tyler's screens, a 12-mesh sieve may have holes ranging from 1.0744 to 1.7602 mm. in width or anywhere between, according to the size of the wire that is used. Fancy trying to sell land that had been measured by a tape that would vary from 1 to 1¾ ft. for every foot that was measured. How impossible would be the transaction. How easy would it be for the seller to give short measure. How difficult it would be for the registry of deeds to make a record that any one could again check up for later transactions.

Now, the user of the word 'mesh' thinks that these are little grains of sand and that the differences don't amount to anything, but think of the perplexity that I am in when I receive data for computing a classifier, as I am constantly doing, that are given to me in meshes instead of exact width of holes. Referring to my table of velocities, a grain of quartz 1 mm. wide settles 93 mm. per second, while a grain 1¾ mm. wide settles at the rate of 140 mm. per second. If I calculate my classifier for 140 mm. per second, and then it is fed with quartz that settles in 93 mm. per second, my classifier will be completely out of gear with the work it has to do. I am obliged to take a mean figure and hope that this will come somewhere near right instead of being given an exact figure with which I can work with precision.

ROBERT H. RICHARDS.

Boston, December 27.

The Greenwater District.

The Editor:

Sir—I had been reading for some time marvelous stories of the great wealth of Greenwater, and I had seen the statement made in many places that it was going to be the "greatest copper camp in America," that the showing in rich copper was very extensive in area, and that the ore was extremely rich. I had come to believe that all this was true, and I felt for some time a desire to get to Greenwater and try to get in on some of this wonderful possibility. Such was my motive in going.

There are two routes from Los Angeles to Greenwater; one by the Santa Fe railroad and the Tonopah & Tidewater (or Borax Smith) railroad, and the other by the Clark road (the Salt Lake route). I went by the Santa Fe. The T. & T. R. R. crosses the Santa Fe at Ludlow, 195 miles from Los Angeles. From there to Dumont, which is the front, is 75 miles. The fare from Los Angeles to Dumont is $10.60.

At Dumont I took the stage for Greenwater, paying $10, which is to be raised to $15. Leaving Los Angeles on Thursday night at 8 o'clock we reached Dumont on Friday morning at 9 o'clock, and the old borax station, 17 miles out, at 4 P. M. There we spent the night, having comfortable beds. Saturday at 3 P. M. we reached Ramsey, 33 miles from the borax station and exactly 50 miles from Dumont. This distance I believe to be accurate, although the stage company attempts to make it longer.

Coming out, I left Ramsey at 6:30 A. M., reaching Amargosa on the Las Vegas & Tonopah railroad at 3:30 P. M., the distance from Ramsey being 48 miles, or possibly 49 miles. At Amargosa I had to remain until 11:30 A. M. the following day, and I could have reached Los Angeles the second morning at 8 o'clock. From Los Angeles by the Clark road one leaves at 8 P. M. (say, Monday), and reaches Ramsey at 1:30 P. M. Wednesday. The fare on the stage from Amargosa to Ramsey is $16, and on the railroad from Los Angeles to Amargosa it is $18.15. One has to stay over night at a stage station by either route. The stages are covered wagons, and the rate of progress is painfully slow, they are generally very much congested with animate and inanimate freight of all kinds. The stage from Dumont at present runs every other day, while from Amargosa it runs daily.

Ramsey is now claiming the title of 'Greenwater', which title has until recently been claimed by Kunze, three miles farther from the railroad. The post-office at present is at Kunze, but it is soon to be moved to Ramsey, which is known as 'Greenwater.' The altitude of Ramsey is about 4,300 ft. above sea-level and Kunze is about 4,800. About two miles beyond Kunze is the settlement of Furnace, which is where the men live who work in the Furnace Creek (the Patsey Clark) properties.

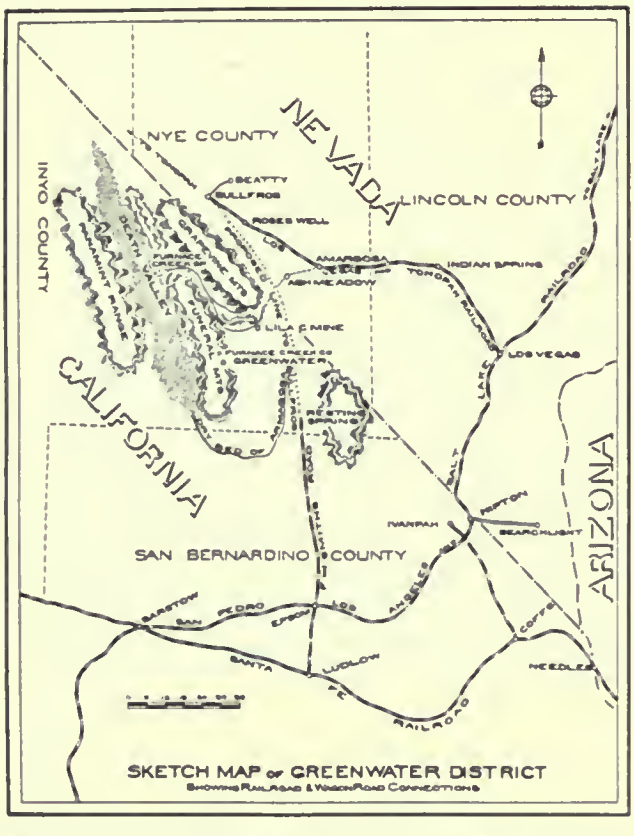
At Ramsey lumber sells for $140 per thousand feet, while flooring costs $175. Water sells for $7 to $10 per barrel, and hay at $100 per ton, coal the same, and other things in proportion. The lodging houses are of canvas and no attempt is made to heat them. Miners in shaft-work get $3.50 per day and board; a two-horse team and driver command $12.50 per day.

I was admitted to the shaft of the Red Boy, 75 ft. deep, and might have gone down the Saratoga, somewhat shallower, had I so desired, but the two are under the same management and I was assured that both were alike, so far as showing went. This showing consisted of a narrow seam of silicious material, carrying some green stains. At the bottom of the shaft there were slips running in all directions and each seemed to carry in places green-stained material about an inch wide. I was not admitted to any other property, nor is it the custom of the district to let strangers see what they have (or have not) got. The Schwab property, purchased from the locators Arthur Kunze and others, is situated on the trail between Ramsey and Kunze. Work seemed to be in progress on three of these locations. At one a gasoline hoist (50 h.p.) was at work and on another one is being erected. These shafts are commonly reported to be over 100 ft. deep, but the exact facts I could not learn. At one of these I saw the vein exposed for a width of perhaps 30 inches. It abounded in green stains, and carried some malachite and a little azurite. The rest might have been chrysocolla. On the dump at this and the Furnace Creek properties a little green-stained material has been collected in separate piles, perhaps a couple of cars of 20 tons each at each dump. This is a generous estimate.

I saw no pyrite anywhere nor could I learn from assayers, or any one else, of the occurrence of any. I did see a minute piece of bornite, said to have come from Willow creek, about fifteen miles from Ramsey. It is my estimate, from what I saw and could learn, that all the properties in the entire Greenwater district, from material thus far taken out, could not contribute together one car (twenty tons) of ore that would run 25%, and that if the stained material now assembled on the various dumps were to be assayed, it would scarcely average 5%. Not a shipment of any size for commercial purposes has been made from the entire district, as far as I could learn, the only so-called 'shipments' being a few burro-loads of samples to beguile speculators.

The Furnace Creek range, in which these deposits occur, appeared to me to be composed wholly of erup-

tive rocks, rhyolite in various stages of alteration. As nearly as I could learn from what I saw the supposed great veins of the Greenwater district are zones of fracturing of considerable width. I saw none of these zones that was less than 30 ft. wide and in many places I thought them much wider, but the true test must be secured from underground developments. Through the seams in this zone the hot waters circulated and effected a large amount of replacement, the material being much silicified, and more or less impregnated with copper and iron. Everywhere they are highly stained with iron oxide and are locally called 'gossan.' I saw no gossan that was the residuum from pyrite, although I looked for it in many places. The iron that has produced these extensive stains was doubtless originally associated with the very small amounts of copper, which, after oxidation, yielded the carbonates and stained the rock green. I tried diligently to learn of any enrichment by gold and silver in the so-called 'gossan' and near the surface of these veins, but while the assayer at Ramsey



said that some of the samples that he had assayed yielded a little gold and silver, it was clear to me that no gold or silver ore of commercial value had been found.

There are probably less than a thousand men scattered through the district. Many of these do not hesitate to express the feeling that it is high time that some discovery should be made of ores of commercial value if the camp is to justify the extravagant claims that have been published regarding it.

It is my impression that the Las Vegas & Tonopah railroad will be extended from Amargosa toward Greenwater such distance as may be requisite to command the traffic. This can be done cheaply and would be a great tonic to the camp in many ways. Much prospecting is going to be done in the hope that discoveries will follow deeper exploration. There is no guide to indicate at what depth water will be struck in any of the workings, disclosing the pyrite that it is fondly hoped to find below the water-level. I learned of no springs along the easterly base of the Funeral range. On the westerly side (the Death Valley slope), I understand that water does occur, but how far above sea-level I do not know. It was impossible for me to go over there without fitting out an expedition to carry food, water, bedding, etc., and even then I should have required the services of a guide.

To illustrate the expansive tendencies of the Greenwater boom, I may relate the following incident concerning one of the properties now offered to an eager public, with reckless display of printer's ink and glittering word pictures of wealth in store for the fortunate investor who comes in upon the ground-floor. I met the prospector that located and sold this property to the promoters, one of whom is a prominent mining man. The price paid the prospector was one thousand dollars and a small block of stock. This property is now capitalized at $1,500,000 in shares of one dollar. It was put on the market at 50 cents per share.

JAMES W. ABBOTT.

Pioche, Nevada, December 12.

The California Miners Association.

The Editor:

Sir—In your comments on the recent annual convention of the California Miners Association you remark that "the California miners were not there;" and that "the attendance was restricted largely to the little coterie that has been keeping the Association alive during the past few years." It may be said that these remarks have given some offense to those who have been earnest in their endeavors to maintain the institution and who have been compelled from force of circumstances to take the lead in its affairs. A circle of persons who meet habitually for any purpose must have some among them who are more earnest than others, and more constant in attendance, and their names naturally become more prominent in the public accounts of the meetings than those who do little actively. Yet this cannot be to their discredit, if the object be a good one. As one of the original organizers of the California Miners Association and a member of the executive and other committees for a dozen years, long association with these gentlemen has convinced one that they are unselfish and have no ulterior motives other than the general benefit of the mining industry and the miners engaged in it. Not having personally attended the last convention—or indeed several preceding it—and not being an officer, I may say this with better grace than any of those who are now more active in the Association.

It is perhaps unfortunate for the general advancement of the Association that the idea is prevalent that its main object continues to be the rehabilitation of hydraulic mining. This was its original purpose and continued so for several years, until the passage of the Caminetti law. Since then it has been devoted to the benefit of mining generally. The quartz and drift miners have had no grievances to take up; and the dredging men have an association of their own, having affiliated only to a slight degree with the California Miners Association, and giving it no active support. The petroleum men have also their own organization. The hydraulic miners themselves, what few there are, have not for several years taken any active part in the deliberations, and have contributed little or no funds. Until the court of last resort passes on pending questions connected with this industry, it is—as you say—a dead issue. Last year all the hydraulic mines of the State only yielded $975,000 in gold. Of this total $635,669 came from the counties of Del Norte, Humboldt, Siskiyou, and Trinity, all of which drain into the non-navigable streams emptying into the Pacific ocean, where there are no legal restrictions against hydraulic mining. This only leaves $339,471 as coming from the counties in the drainage basins of the Sacramento and San Joaquin rivers, where the Caminetti law is in force and where the California Debris Commission has jurisdiction. If the issue is not dead the hydraulic mines

virtually are, judging by this small showing for a whole year for what was at one time an industry supposed to yield eight or ten millions annually. The industry as a whole is decreasing in importance each year. In fact the dredging machines in California are now yielding annually $460,000 more than the hydraulic, drift, and surface placers of the State combined, and will shortly yield a million dollars more.

It may be confessed that the proceedings of the convention at Nevada City a year ago were largely devoted to consideration of hydraulic mining interests. Possibly it was for this reason that few of the prominent local quartz miners took any active part in the deliberations. The men connected with the management of the Association are endeavoring to excite a more general interest in its affairs, so that the organization may be maintained on broader lines than originally designated. If the drift and quartz miners need no protective legislation just at present, they may need it at some time. Both the dredge and copper miners have certain annoyances to contend with even now and these may become serious. Without some organization little can be effected as was proved in the case of the hydraulic miners, many of whom fought single-handed for years to defend what they considered their rights. It was only when the California Miners Association was formed that either the State or Federal Government took any notice of their demand.

I think the California Miners Association is worthy of the support of the whole mining community of the State if only for the moral effect it affords to the industry, and the fact that in accordance with modern practice the class of persons it represents are organized for mutual benefit and protection. That some self-seeking persons may have used it for political advancement or notoriety is no argument against its existence. The better class is far in the ascendant in its councils. Let more men of prominence in the industry give their names and support, as they should do, and it will prosper. The miners themselves ought to maintain it, by which I mean the owners, superintendents, managers, engineers, etc. The ordinary working miners will not furnish funds for anything of this sort, as experience has proved. Nor should the Association be compelled to ask financial support from mining machinery men, as it has had to do, and is doing. In fact most of the available funds are from this source. I personally know that most of these gentlemen would rather see the actual miners themselves take hold of the organization, manage and maintain it. It has been a sort of semi-compulsion which has led many of them to take any active part in the affairs.

As to publication of papers in the official proceedings only, I quite agree with you that they should be given at once to the press as soon as read and not delayed until apt to be 'stale.' But the present method has been forced upon the Association by the necessity of publishing regular proceedings for subscribing members and getting some profit, through advertisements, at the same time. All this by reason of lack of funds.

The new president is an active young man long identified prominently with the mining interests. He has pounded the drill, put in timbers, dug and tended ditch, and worked in gravel and quartz mines, as miner, foreman, superintendent, and manager. He has been connected with the Association since its beginning, and indeed has once before presided over its deliberations, and knows its weak points and its necessities. Let us trust that he will be able to inaugurate a broader spirit and policy and induce prominent men to join in the good work. He can do nothing alone. All in any way interested in the varied mining industries of the State should lend a helping hand. With more active workers to choose from there can be no further intimation from any source that a few men only are 'running' the organization and for one interest alone.

CHARLES G. YALE.

San Francisco, December 28.

The Moore and Butters Filters.

The Editor:

Sir—The article by Mr. Nutter on the Moore filter in your issue of December 15 is both interesting and instructive. There are, however, several serious errors in it which do an injustice to the Butters filter, and which should be corrected immediately. In discussing a plant to treat 350 tons of slime, as described by Mr. Nutter, a comparison with the plant erected (at Millers, in Nevada), for the Tonopah company, will be in order. This Butters slime-filter consists of 216 leaves, and would handle about 300 tons of the Liberty Bell slime, and 250 leaves would easily handle the mill output of 350 tons per day. Such a plant would require, instead of eight 7-in. pumps as estimated by Mr. Nutter, only one pump that would transfer the pulp or water in ten minutes. It is very difficult to calculate centrifugal pump capacities working on a material of such variable consistency as slime, but judging from previous experience with different slimes a 9-in. pump would be amply large; and as 48-in. pumps are regularly used to transfer sand in dredging, it is hardly in order to call a 9-in. pump "large," or to consider it or its valves difficult of operation.

The light crane mentioned by Mr. Nutter would not be necessary, as a half-ton chain-block, with crawl, would handle the Butters leaves when such handling became necessary, which, by the way, would be rare.

As regards the quantity of slime to be pumped, it is certainly not fair to require the handling of the large quantity needed to fill Mr. Nutter's filter-vats, which are not designed as is the Butters filter-box, to contain barely enough slime to cover the leaves. Neither is it a fair proposition to require that the slime be pumped against the maximum head of 19 ft., when a properly designed plant, even when built on level ground, has a maximum lift of 10 ft. and a minimum of 0 ft. In other words, one properly designed box for 250 Butters leaves will contain approximately 7,000 cu. ft. instead of the 24,000 cu. ft. capacity of the eight filter-vats that Mr. Nutter considers necessary. The use of such a box would make available for water and slime storage the vats now used for filtering and washing, thus obviating the necessity of installing the two storage tanks he mentions.

Instead of the time items being as given by Mr. Nutter in the cycle of operations, the following in the opinion of the writer, would more nearly approximate actual running conditions:

Operations.	Moore.	Butters.	Butters gravity.
Loading	1 hr.	1 hr.	1 hr.
Transferring (filters)	10 min. (pulp)	10 min.	2 min.
Filling with water	Nil	10 "	5 "
Washing	1 hr.	1 hr.	1 hr.
Discharging	10 min.	10 min.	10 min.
Transferring (filters)	10 " (pulp)	10 "	2 "
Total	2 hr. 30 min.	2 hr. 40 min.	2 hr. 19 min.

Without knowing the conditions as they exist at the Liberty Bell that would influence the cost of a filter installation, such as present arrangement of vats and tanks, power required by the Moore filter, ground contours, etc., I am unable to carry this comparison to its logical conclusion, wherefore it is incomplete.

A statement from Mr. Nutter as to why it would not be better to install a properly designed filter-box; why a gravity plant could not be placed; and why one 9-in. pump would not be sufficient, would seem to be in order.

MARK R. LAMB.

Mexico City, December 22.

The Copper of Shasta County, California.---II.

Written for the MINING AND SCIENTIFIC PRESS
By DONALD F. CAMPBELL.

The history of the active development of the copper resources of Shasta county dates back to 1896, when a strong English corporation entered the field and disclosed the great mass of ore at Iron Mountain. Prior to this, Shasta county had been the scene of some placer and pocket mining, while the outcrops of the copper deposits had yielded large returns in silver and gold, before the fact was realized that the most profitable and permanent industry was to be found in the mining of base metals. As early as the sixties, however, small shipments of oxidized copper ore were made from the Bully Hill district, and taken round the Horn to the Swansea smelters. The development of the Iron Mountain mine marked the birth of the present thriving copper industry. This mine was worked successfully as a silver and gold mine, the gossan being treated in a 10-stamp mill and the sulphides chlorinated. The chief product was silver, but the fall in price during 1893 and the presence of base ores brought the profit to zero. It was then that English capital took hold of this mine and started operations on a large scale.

This district may well be considered in detail, as it is typical of the western, or most important part of the belt, which includes also the Balaklala, Trinity, and Mammoth copper mines. In the eastern portion there are a number of mines of a different type, of which the Bully Hill and Afterthought may be taken for detailed consideration. In the former district the mines are entirely exploited by adits, while in the latter, the narrow and deep orebodies are mostly explored through shafts.

The Iron Mountain mine, the richest and most developed in the district, is connected with the smelter and Southern Pacific railroad by a narrow-gauge railroad 11 miles long and of 3.3% grade. This mountain road climbs about 2,000 ft. and is one of the most remarkable in the Western States. The numerous curves, only partially compensated, deep cuts, high trestles, and loop make it a road that would naturally be expensive to construct and maintain. The problem of railroading under these adverse conditions, hauling cordwood, flux, and supplies from the main line, switching roasted and sulphide ores in an awkwardly constructed yard, and above all, keeping up an adequate supply of ore from the mine with a small storage capacity at the smelter, has required great ingenuity and care.

Keswick, the pioneer smelter town of this important copper region, was once the scene of an activity that has never been repeated. Before pyrite smelting was introduced, the ore was mostly roasted in open piles or stalls, giving employment to hundreds of men, and great quantities of coke were required. Cord wood, partly cut from the adjacent hills and later floated down the Sacramento river, was used at the rate of 60,000 cords per year before the introduction of electric power. These operations resulted in a payroll of 1,200 men at the smelter alone. This is a great contrast to the present methods. The new smelter at Kennett is typical of a modern plant; but it is due to the development of ideas resulting from many costly experiments undertaken at Keswick. Almost every misfortune that could befall a mine and smelter had befallen this property, the list of troubles including mine fires, labor difficulties, and litigation. In spite of this, however, the problem of smelting the ores of Shasta county was worked out entirely at Keswick, the old method of roasting and smelting with coke being gradually improved and ultimately culminated in the adoption of pyrite smelting, with a remarkable run of 11 days without a pound of coke in 1905. The Keswick smeltermen have solved the local problem of ore reduction, and it is satisfactory to see such dogged industrial determination give good results, and to note that the men who directed the first smelter are now applying the methods that were developed by their skill.

The mining of the Iron Mountain orebody has presented several difficulties that are full of interest. For some years the mine has been on fire and the resulting gas and heat have made the underground conditions very bad.

Keswick Smelter.

Blast furnaces, roasters and converters, making blister copper.

That spontaneous combustion often accounts for outbreaks of fire is probable, because the fine pyrite dust, when in contact with decaying timber in a stagnant atmosphere will generate sufficient heat by decomposition to burn. The fire makes the temperature of the rock and working places high and fills the atmosphere of the mine with sulphurous acid gas, while the water is a strong solution of iron and copper sulphates with free sulphuric acid.

The conditions that seem to favor fire are rottiug timber covered with pyrite dust in a semi-permeable filling in which small pieces of ore occur. Rock temperatures of 600° F. may be observed in the immediate neighborhood of the fires and yet rock of this temperature has been mined—a fact creditable to the determination of the management. The system of miuing has been to extract the ore in horizontal slices, each 10 ft. thick. In addition to this, a sub-division is made on each horizontal slice so, that the two end stopes are separated by a centre pillar to prevent the spread of fire. A main adit is driveu through the country-rock and across the orebody to the farther side. From this, drifts divide the stope into a number of pillars about 50 ft. square. These are 'robbed' by slices one set in width and the whole stope is 'worked home,' the entire space being well packed with filling and the timber left in position. No opening of more than two sets in width is left unfilled. The system of working is shown in the accompanying diagram.

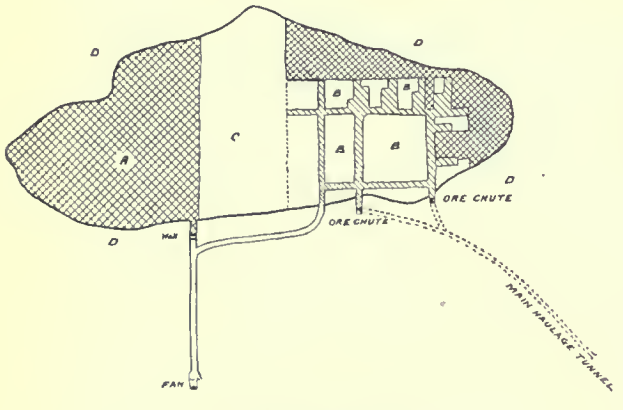


Fig. 1. Method of Working.

A, Filled ground. B, Undeveloped ore. C, Fire pillar. D, Country rock.

The rock breaks easily, being traversed by a number of fissures in certain well-defined directions; often blasting is unnecessary. In driving through old filling, serious runs of fine calcined dust have occurred without warning, which together with a sudden outburst of gas, prove dangerous. In working the hottest places where there is fire, a careful watch is kept on the rock temperature and a plentiful supply of water is piped to the face. Timbers are soaked and, after blasting, the rock is cooled with a spray. Ore may be worked at a temperature of over 800° F., but at this heat the fine ore will burn as it falls through the air, and in blasting the combustion of the fine dust makes so much gas that it is often difficult to get back directly afterward, which is necessary, as the timbers must be constantly wetted. With a rock temperature of this exceptional intensity, the air at six feet from the face can be maintained at 100° to 110° by the system of ventilation used. For blasting at this temperature, the holes are cooled by leaving a hose running in them for some time, wrapping the powder in asbestos or rags and lighting the fuse before putting the powder in the holes.

Stopes are sometimes temporarily lost through an outbreak of fire and in such cases it may be advisable to remove all machinery, cars, and rails, and shoot down timbers or build walls, so as to isolate the danger zone; but in some cases the fire may be fought and successfully subdued. If a mass of ore is known to be very hot and surrounded by smouldering filling, it is better to approach it from above and always with a low drift. If the fire is above, or the drift is broken high, the fire will fall on the lagging above the caps, where it cannot be fought as well as on the floor.

The conditions are not good for efficiency among miners, but the Italians, who alone will work under such trying circumstances, work fairly well. The gas, acid water, and great heat make extraction difficult, for, although the temperature, usually about 90° and in some cases as high as 110° F., is not so intense, it must be remembered that a dry heat is very much better than this steam-laden, gaseous atmosphere with strongly acid and coppery water dripping in many places. The cost of driving adits in the country rock—a silicified and sheared rhyolite—is shown in a table below, while the cost of extracting ore is about $1.50 per ton. The mine has several natural advantages, which help materially in keeping down the costs of extraction. The ore is easy to break and blasting is often unnecessary. Furthermore, there is no hoisting or pumping, as the mine is entirely above the level of the gulch in which the camp is situated.

The system of ventilation is especially interesting. Several Sturtevant fans, 5 ft. diam., are used to blow air into the workings. These are carefully regulated so as to maintain an equilibrium at the end of the workings and hold back the gas in the filling, thus placing the combustible material in a neutral atmosphere. If a proper statical pressure is maintained, air will not penetrate the filling so as to fan the smoldering timbers to a blaze, and the back pressure cannot force the gas into the workings. The system, though it is simplicity itself, has solved what might have seemed an insurmountable difficulty.

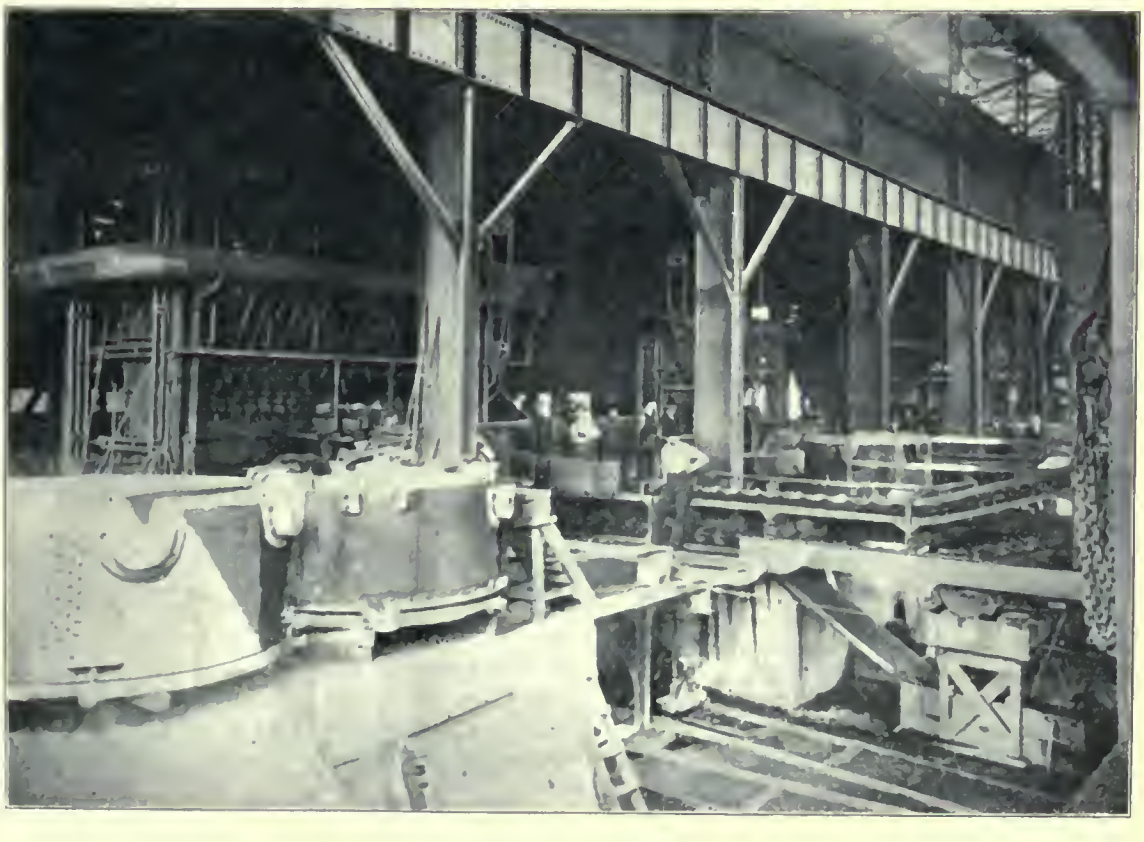
Filling for the mine is partly obtained by driving for development in country rock and partly by quarrying on the surface. The ore is loaded directly into trolley cars underground and taken to bins above the railroad terminal. Here it passes through a coarse crusher and after screening, the various sizes are passed down a gravity incline to separate railroad bunkers, where it is shot into the railroad cars and taken to the lower railroad termi-

nal, to be put on the storage piles or transferred to broad-gauge cars, accordiug as assays or circumstances require. Generally three sizes are separated: Coarse or 'run of mine' ore; 'nuts,' screened from 2 to 4 in.; and 'fines.' Special sizes are made according to order for some sul-

Kennett Smelter.

Simple arrangement for single concentration to low-grade matte.

phur burners, etc. The cost of transferring ore from narrow-gauge cars to stock piles, and then to crushing and sizing plant and loading on broad-gauge cars is economically carried out. The different grades of ore, in separate piles, are loaded with a steam-shovel and may



United States Smelter.

Showing furnaces, settlers, and slag disposal.

be mixed to get any desired grade. The cars are then switched and dumped into bunkers over the crusher and trommels from which the ore passes on to a picking belt and thence into broad-gauge cars. By this means the ore can be transferred, crushed, sized, and picked clean

transferring used to be often trebled. A hydraulic cylinder was put in the bottom of the bin, fitted by a steel plough 2 by 4 in. by 6 ft., which was fixed transversely across the end of the piston. By working this slowly to and fro, to make an undercut, the packing of the ore was entirely prevented, and a steady stream of fine ran down the chute, effecting a great saving in cost.

An important asset is the mine-water, and one which is highly profitable. The water contains free sulphuric acid, copper and ferrous sulphates, the latter being soon

of waste and zinky stuff, and loaded, all at a cost of about six cents per ton, which includes labor and supplies.

An ingenious device has been employed to overcome the difficulty of packing the fine ore in the bunkers. The ore cakes hard and forms an arch, so that the cost of

oxidized to ferric sulphate on exposure to air. This water, coming from the mines at a temperature varying from 80 to 130° F., is led through a series of three precipitation vats. Each vat has three compartments in parallel so that one is usually being emptied and two are in use. Their length is 200 ft. each, with an inclination of about one-half per cent. In each vat or box there are two or three riffles, but these are often dispensed with, if the water is plentiful. Scrap tin-plate is used for precipitation, and is more economical than scrap-iron, because the action is more rapid and less handling is necessary. The excess of free acid in the water liberates great quantities of hydrogen. Attempts to neutralize this acid have not proved successful, and it increases the consumption of iron to such an extent that the economic limit of copper extraction is attained when the cost of iron dissolved is equal to the value of copper obtained. This economic limit is reached when the water escapes with about ten parts per million of metallic copper.

The selection of scrap tin-plate is a matter of some importance. Fruit and fish canneries, coal-oil dealers, and the like, have splendid material, but the supply is somewhat limited and must be bought at seasonable opportunities. Lacquered tin must be avoided, as it is most persistent in resisting solution, and will often take weeks to dissolve, whereas with bright tin, the bundles are often dissolved as quickly as two men can feed them into the first vat. A good supply of water under high pressure is laid on, so that the tin can be well scoured if it becomes coated or dull. Almost the whole of the copper is deposited in the first box, but assays are regularly made to determine the losses, the outlet, and the extraction in each box. The mine-water will usually carry from 1,000 to 3,000 parts per 1,000,000 of metallic copper, but the first box will reduce this to 15 or 20 parts, and the outlet should not exceed 8 to 10 parts. With this extraction the economic limit is reached, the consumption of iron by the free acid being too high to justify the extraction of the remaining copper. When sufficient copper is precipitated, the water is sluiced off from a box, the tin raked out, and water syphoned to the next vat, and the copper cement taken to the drying furnace. This assays about 83% copper and contains some sulphuric acid. If left in a damp state in the open air, it will sometimes get red hot and form a fused mass. It is largely used for painting the bottoms of ships to prevent the growth of barnacles, owing to its poisonous character.

At the Mammoth mine the lode is extracted in slices and timbering is put in. The ore is entirely removed and the roof allowed to come down. From the mine, the ore is transported to the smelter, a distance of about three miles, by an aerial ropeway which has not proved altogether satisfactory. The Bully Hill mine differs in many respects from those on the western portion of the belt. It was opened as a gold mine, and the gossan was worked with indifferent results, until copper ore was developed at depth. Bully Hill is composed of basic and acidic eruptives, principally rhyolites and basalts, with a series of mineralized shear-zones in which lenses of ore and pyritic impregnations occur. The mine is developed on the upper levels by a number of adits, and in depth by a shaft 600 ft. deep, equipped with an electric hoist. The irregularity of the ore deposits and ill-defined zones of mineralization, make the development of this mine a matter of difficulty. Drifts are generally driven about 20 ft. in the foot-wall, cross-cuts to the vein being made at regular intervals. In this way a number of valuable deposits have been discovered, in some cases chalcopyrite, several feet in thickness, being found. In the upper workings a gouge occurs in the shear-zone that is rich in oxidized copper ore. The cost of extraction is not easily determined, as a large amount of the rock extracted is used for filling, and data as to costs are not available.

The same company is actively developing mines at Winthrop and in the adjoining Copper City district, and with the completion of a railroad up the Pitt river, the prospects of a considerable output of copper and precious metals are excellent. This ore is more silicious and nearly self-fluxing, although small quantities of iron ore and limestone are used to flux those containing an excess of silica. Barite is a marked constituent of this and the Afterthought ore, while zinc-blende is also found in large quantity. In the past, the cost of freight has killed the profitable extraction of copper, as the hauling of coke cost $8 per ton, in addition to the exorbitant rates on the Southern Pacific and Bellavista railroads. The Afterthought mine resembles the Bully Hill in many respects, but the quantity of ore is less, and the associated minerals are very troublesome. Large quantities of zinc-blende and barite occur in this district, and these minerals have caused incessant trouble to the smeltermen.

The larger and more important mines are those that occur in the western part of the belt, but in the Bully Hill district the ores are often of much higher grade, both in copper and precious metals. Shasta county will undoubtedly make its mark on copper statistics in the next few years, and while the development of large ore-bodies is more than probable, the present smelters under construction will be smelting 3,000 or 4,000 tons of ore per day in the near future.

An Interesting Letter.

The following communication was received by two mining engineers who were in Nevada recently:

GoldField Hotel, GoldField.

Messrs. Smith & Jones

Dear Sirs I see by Our Daly that You are hear looking for some Good Properties and we have Many of them from one thousand to Five Thousand to Ten Thousand up to One Hundred and tweutyfive Thousand per Groupe of Claimes and in Nos fromthree to Eight in a Groupe all have well Defined Ledges that assay from threeto Twenty three Dollars per Tone and some PanFree Gold to the Valuation of twenty to thirty dols and we Have 4 Groups in the Heart of the GoldField District surounded by Properties that Money can not By such as the WhiteRock Ajoiniug the January Mines and Surounded by such Notied Mining Propertiesas the Florance. the Combination. the Jumbo. the Mowhawk. and the Redtop. all Heavy Shipers with great Recards. as Heavy Producers for thire age.

REGULAR stage service, twice a week, will be maintained this winter between Valdez and Fairbanks. The new winter trail saves fifty miles over the old one.

Car Shortage in the Middle West.

Written for the MINING AND SCIENTIFIC PRESS
By an Occasional Contributor.

Car shortage is a perennial trouble in the coal business. This year it has been unusually severe and protests have been heard on all sides. After a long and disastrous strike, a dull summer, and a lagging autumn, winter sets in, and the demand for coal is accentuated just at the moment when the rivers threaten to freeze and railway transportation breaks down. It is no wonder that the coal operator feels sore. Car shortage at this time of the year is expected, and a normal car shortage is accepted as one of the ills incident to business, but this year it is no exaggeration to say that in many quarters coal transportation is simply demoralized. This works peculiar hardship on the coal operator for a variety of reasons.

In normal times the producing capacity of the coal mines of the Middle West is 30 to 40% above the annual demand. The coal of these fields will not stand storage and must always be mined as used. The largest single market is afforded by the railways, and in this territory the railways are busiest in the fall and winter. It is then that the crops are moved and that Christmas and other goods are shipped into the rural districts to remove the surplus wealth accumulated by the farmer. It is then that coal itself must be moved to heat and light the towns, homes, and factories of the great Northwest. Coal itself is the largest single item of traffic on most of the roads of the region. It affords from 25% of the traffic of the granger lines to 60% of that of certain coal roads. In the case of an average road such as the Illinois Central, 34% of the traffic is coal, and its movement is largely concentrated in the winter months.

In order to meet the demand of the winter, the collieries must be built for a large annual capacity. The result is that they are run at a loss during the summer, being operated only enough days per week to hold the men, and then mainly on company work—driving of entries and turning of rooms in preparation for the next winter. The average colliery of the region works 200 to 225 days in the year only, so that the "loss to the miners due to loss of time," usually figured after a strike, is largely a myth. In most cases the miner may cheerfully strike a hundred days in the year without loss to himself if he but bunch his strikes in the summer season.

In an effort to spread the work around, the miners have adopted various restrictive measures, some openly and some not so openly, which have had the general effect of increasing the number and size of the collieries, because, owing to the fundamental fact that the coal can not be economically stored, the mining must be concentrated in the winter months.

At the time of the anthracite strike prices of bituminous coal became abnormal. A large amount of new capital was attracted to the business. In the main this went into the purchase of nearly worked out or badly situated collieries, which their more experienced owners were glad to exchange for the cash with which to open new mines. As at that time any mine not contracted ahead could make a profit, every one was temporarily happy. The legacy, however, has been a load on the coal industry ever since, and these sudden spurts, attracting new capital and bringing in as they do a large number of inexperienced miners and operators, prove a heavy burden in the following years. As a result, during the recent years of prosperity the coal business has been in a bad way, as any business will be when supply exceeds demand.

In the meantime the great Northwest, which absorbs the surplus coal of the central and middle western States, has been growing—growing at an unsuspected rate. For the first time since the anthracite strike there seems now to be a real demand for all the bituminous coal that can be produced. The demand is probably slightly fictitious since last year, owing to the open winter, coal sold in December lower than in August, and retailers who stocked up in the fall lost money. Retail stocks last fall were certainly short. At the same time shipments into and through Chicago and St. Louis in the first ten months of 1906 were 25 to 30% higher than for the corresponding months of 1905, and this includes the period of the strike and the normally dull months. The coal mines, by a purely accidental chain of circumstances, are prepared to meet this gratifying and unusual demand, but the railways are failing them.

At the beginning of the strike one large railway system on which coal furnishes about one-third the traffic, had 40,000 coal cars in service. Foreseeing the difficulty, the general freight agent issued instructions for his subordinates to make particular efforts to secure shipments of lumber and other goods that might go in the coal cars. The result was that the company had no idle cars except such as it wished to use for storing coal. Practically one-third of its rolling stock was promptly absorbed by the demand designed to be met by the other two-thirds. Again; this fall a granger line depending on a coal road for its fuel-supply found its coal pile getting low. Upon demanding coal, it was told there were no cars. These being furnished, it was said there were no locomotives. These in turn being furnished, it required strenuous effort and vigorous pleas to recover them. It is foolish to say that cars and engines are not needed; that tracks and terminals are equally out of date is perfectly well known to every shipper except possibly a favored few. Deeper than all this is the fact that the railways are not up-to-date in their management of freight. Anyone who has tried in the last few months to recover freight lost in transit, knows that methods are defective when such things as steam boilers, so large that they require special cars for their transportation, disappear absolutely without leaving a trace on the company records and require the services of a private detective employed by the shipper to find them! Either the railway business has grown too vast for its managers, or they have been putting in more time watching the ticker than studying their own organization. The facts now being made public regarding the slow rate of travel for freight have long been known to shippers. They merely emphasize the statement that despite the almost total lack of organization of the business, the river steamboat today actually delivers freight more rapidly than the railway.

ORE STEALING.—That a form of 'high-grading' flourishes in Western Australia has been proved by inquiries instituted by police detectives in Victoria, resulting in a full confirmation of the suspicion that considerable quantities of Western Australian gold had been disposed of to Bendigo buyers, the number of whom is said to be out of all proportion to the requirements of legitimate business. It is now believed that the value of the gold annually stolen from the Western Australian mines is fully as large as estimated at the commencement of the investigations by the Royal Commission. It has also been ascertained that gold stealing is largely practised in Victoria, and the State Minister for Mines is to be asked not only to cancel all existing gold buyers' licenses, but also to declare all sales to be illegal unless effected through the Melbourne Mint.

MORE than 11,000,000 pieces of mail went astray in the United States last year because they were not even directed well enough for the experts to decipher the names and addresses.

Standardization of Screens.

The committee on standardization of screens, appointed by the council of the Institution of Mining and Metallurgy, London, has reported by its chairman, Mr. Walter McDermott, that it recommends the adoption of the following standard laboratory screens:

Mesh.	Diameter of wire.	Size of aperture.	Screening area.
	Inch.	Inch.	%
5	0.1	0.1	25.00
8	0.063	0.062	24.60
10	0.05	0.05	25.00
12	0.0417	0.0416	24.92
16	0.0313	0.0312	24.92
20	0.025	0.025	25.00
25	0.02	0.02	25.00
30	0.0167	0.0166	24.80
35	0.0143	0.0142	24.70
40	0.0125	0.0125	25.00
50	0.01	0.01	25.00
60	0.0083	0.0083	24.80
70	0.0071	0.0071	24.70
80	0.0063	0.0062	24.60
100	0.005	0.005	25.00
150	0.0033	0.0033	24.50
200	0.0025	0.0025	25.00

Owing to difficulties in wire-drawing and in the weaving of wire-cloth, absolute accuracy to the fourth place of decimals of an inch is unattainable with uniformity of 25% of screening area; but the above table is so near to theoretical perfection, and the unavoidable irregularities of screening tests themselves are so wide that any inaccuracies in the table would be absolutely immaterial in practice. It is not possible to weave the 200-mesh screen except in what is known as 'twilled' or double wire, and it is questionable whether the table should not stop at 150 mesh as being fine enough for all practical sizing tests by screen.

The advantages of the series are:

1. That a definite ratio between aperture and mesh is secured.

2. That by adopting a screening area of 25%, the wires are absolutely 'locked' in position, thereby preventing shifting and consequent irregularity in the size of aperture.

3. That the ratio between wire and aperture in all meshes being constant, the 'cup' factor is also constant.

4. That as the table is based on the curve of seriation, any other sizes of mesh can be readily determined.

The Committee appends a memorandum explaining in some detail the grounds and arguments upon which their recommendations are based, and they desire to add that these recommendations are the result of the most careful consideration of the suggestions of users of screens in all parts of the world, and of the views of British and American manufacturers.

In an appendix the Committee states that, assuming the adoption of a standard series of screens, which makers of wire-cloth could supply, there was practical unanimity as to the advantages of retaining the description of the various sizes by "mesh per linear inch," for the following reasons:

Those who objected to the use of the term 'mesh' based their objections on the fact that in the past it had not denoted the size of aperture; but as the whole object of establishing a laboratory standard would be to fix definitely a certain aperture for a certain mesh, it would be simply a matter of convenience of terms as to whether a screen were described as a certain 'mesh,' or with apertures expressed in decimals. There could be little doubt that in practice engineers would continue to use the term 'mesh' by choice, because it is shorter, really descriptive, easily remembered, and precisely as accurate as, because interchangeable with, a certain size of aperture. An agreed standard table giving the size of aperture in decimals of an inch, for each standard mesh, would obviate any confusion. The suggestion of one or two engineers that in future aperture should always be specified alone would be unworkable in many cases, and would not necessarily ensure accuracy or uniformity. Micrometer measurements of fine wires when once woven and crimped are not always to be relied on, and uneven weaving would in practice vitiate conclusions as to size of aperture much more than in the case of the use of standard screens specially prepared for laboratory use. The dependence on every individual who reports screening tests to verify the measurement of such screens as he happens to have by means of a micrometer, even if advisable or practicable, would produce results of grading that could not easily be made comparable with results obtained elsewhere. The attempt to use a standard of apertures in arithmetical ratio, accurate to two or three places of decimals, is pronounced impracticable by wire-cloth makers; and in any case would only prove to be the introduction of a new arbitrary scale of grading, differing greatly from past practice, and offering no advantage over an agreed standard set of screens such as are now advocated.

The report of the Standardization Committee of the Transvaal Chamber of Mines covers a larger field than the Mesh Committee of the Institution has at present in view, and enters on the question of large-scale manufacture of wire-cloth and screens and their use in actual crushing operations. As regards the description of screens in mills, the Mesh Committee does not propose for the moment to put forward any suggestions. There are difficulties to be considered from the fact that managers of mines are likely to be guided by personal opinions of expediency in connection with the kind of ore, type of crusher, cost of material, and subsequent processes of treatment. It is well known that different ores, different quantities of water, wet or dry crushing, and different crushers, all give varying characters of discharge through exactly the same screen. The Committee, therefore, recommends in the first instance, the establishment of one uniform standard method of expressing grading analyses of all mill products, in the laboratory, which would enable accurate comparisons to be made.

Only comparative accuracy can be attained in the description of mill-screens made in commercial quantities, owing to the fact that, both in the drawing of the wire and in the weaving, considerable irregularity always occurs.

There is practical unanimity in approving the adoption of a standard table which, while not departing much in the size of aperture from what is already associated with certain commonly used meshes, would secure a regular arithmetical ratio between mesh and aperture. In considering the table embodied in the Committee's report the following points should be kept in view:

There must be limits both at the coarse and fine ends of the table, to be determined by consideration of utility, common practice, and the requirements of manufacture. The number of sizes between these limits should be reasonable, for it is not desirable to introduce excessive refinements and a large number of screens in the laboratory; and it is not necessary to ask makers to manufacture in small quantities with accuracy, and keep in stock a number of standards which the great majority of engineers will never use in practice. The engineer who requires special refinements in a particular case can use any kind of screen and, by giving its aperture, enable comparison to be made with the nearest standard mesh. Grading by screens can never be exactly scientific as a measure of the size of particles, and therefore it is useless to pretend to unnecessary refinements; and the usual practical requirements in ore treatment may be perfectly well secured in the classification of particles by a comparatively few screen-sizes, as hitherto. As an illus-

tration of the futility of taking screen grading as an exact scientific measurement of particles, it is only necessary to point out that the actual size of the maximum particles passing through any given screen varies with different ores, different methods of grinding, and different methods of using the screens.

After consultation with manufacturers of wire-cloth, it appears that there should be no difficulty in getting makers to weave accurately the small quantities of the standard screening recommended by the Committee to supply the demands of all engineers for laboratory purposes.

There seems to be a general opinion that material passing the finest screen of any standard series should be divided into two classes, and not be described under the one heading of 'slimes.' Various suggestions have been made as to the method of division and as to the terms to used for describing the three degrees of fineness of particles. The general opinion seems to be that all material coarser than 150 mesh should be described as 'sand'—coarse or fine, if preferred; that the portion passing 150 mesh, but readily settling in water, should be described by some such term as 'meal;' and that the term 'slimes' should be limited to particles which settle slowly in water. It may be difficult to get any general agreement as to the division between 'meal' and 'slimes;' and even if this be made arbitrarily, it will remain a fact that two materials having the same settling speeds may not be of the same size of particles, character, or permeability. Some such rough division of the two classes would, however, tend to greater accuracy and uniformity of description than is usual at present, and it is suggested by the Mesh Committee that particles passing 150 mesh, but settling in — minutes in a — inch column of water be described as 'meal.' The limiting factors in this definition are to be determined by subsequent discussion among metallurgical engineers.

THROUGHOUT three centuries the philosophical faculty was predominant in its position and influence in the university. It had come to represent a body of more or less abstract instruction covering by far the greater part of the existing field of human knowledge, and, it must be said, divorced largely from the real things to which it properly belonged. In the early history of universities it constituted a sort of purveyor of privileged or aristocratic learning ostensibly of better birth than the professional faculties of law and medicine, which had the misfortune to deal with the actualities of life on which the welfare and safety of communities no less than the rights and duties of individuals are fundamentally based. This conventional class distinction constituting a kind of snobbery of learning was the real influence or force so completely overcome by the movements of humanism and the reformation, and it has bequeathed to us the useless and senseless term 'pure' science as opposed to applied science; as if there could be in some way a science politely distilled as an essence of learning separated from the realities with which absolutely all science whatever has to deal and without which no science whatever can exist.—*William H. Burr.*

THE vagaries of unfair freight rates are exemplified in a striking way by the fact that a consignment of machinery sent from San Francisco to a mine in Rhodesia, in south-central Africa, was transported cheaper than the same material could be sent to Goldfield, Nevada. In the one case it had to cross the American continent, traverse the Atlantic to England, thence to Beira on the east coast of Africa, and then by train to the interior—a total distance of over 15,000 miles, as against 800 miles to the mining town in Nevada. Comment is superfluous.

Weight of Charge as Affecting Reduction in Silver-Lead Smelting.

Written for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

In 1896, George B. Lee, at that time superintendent at the Union Smelting Works, Leadville, Colo., was much worried by blast-furnace lead losses amounting to upward of 25% of the total lead charged. The slag was clean, the matte low, the furnaces fair on top, but still this loss occurred shift after shift. Sometimes not a single bar of base-bullion was dipped on some furnaces for two shifts. Several metallurgists were consulted, but, after trying their suggestions, the same thing continued. The amount of matte produced was smaller than it should be; and the furnaces began to blow and to settle badly. One after another of the furnaces was run down and the lead appeared to have gone into the wall accretions. One furnace after ten days' running had the accretions due ordinarily to two or three months. The heat was evidently too high up, and the lowest permissible limit of fuel had been reached (14.5 to 15% of Starkville coke with 20% of ash—but no charcoal). The furnaces were low and the ores included much very fine roasted sulphides containing 10% zinc.

Robert D. Rhodes came from the Arkansas Valley works near-by, and puzzled over it, and suggested thicker layers in heavier charges. Mr. Lee essayed this by feeding two fuel charges, then two ore charges. Somehow the night feeder got mixed about it, and started to feed four fuel, then four ore charges. This made a layer of coke of 600 lb., a layer of charge of 4,000 lb., and a layer of slag of 1,500 lb., so that the coke layers were separated by 5,500 lb. of cold material to be smelted. This seemed excessive for a furnace 13 by 130 in. at the charge-floor, but the queer thing was that all trouble ceased. The furnaces reduced well, ran very fast, and kept in splendid condition. Mr. Lee's idea was that with the thinner layers the fuel was almost continuous, while in the new way there was a serious of breaks, making it harder for the fire to climb up, and besides the more fusible slag was farther away and therefore less liable to be melted by the coke below it.

Both A. S. Dwight and Anton Eilers suggested that the ore was too coarse, and would reduce better if made finer, so as to retard and come more intimately in contact with the reducing gases. It was found that this helped also.

ONE hundred years ago, according to *The Copper Handbook*, the mines of the globe produced an average of about ten thousand tons of long copper yearly—less than the present yearly output of either nickel or aluminum—while in 1906 production was at the rate of 15,000 long tons per week, and there is much talk of a copper famine—to which color is given by the present price of the metal, which is higher than for 25 years past. In 1905 there were fifteen individual companies each of which produced more copper than all the mines of the globe combined produced in 1805, and two mines, each of which made as much of the metal last year as all of the mines of the world made during the first five years of the nineteenth century, the two mines in question being the Calumet & Hecla of Michigan, and the Anaconda of Montana.

Of the fifteen mines of the globe that made 25,000,000 lb. or more each of refined copper in 1905, ten are in the United States, while there is one in Mexico, in Spain, in Germany, and in Japan.

AS CAPITAL becomes abundant the interest or profit which it can obtain becomes lower, on account of competition among the capitalists themselves.

Cyanide Clean-up.

By James E. Thomas.

*In designing a milling plant it has always been the practice to erect a separate room for cleaning and pressing amalgam, and for treating any rich product, such as die sand, etc., and I think it is still more important that a separate room or floor should be set aside for the corresponding operations in a cyanide plant, as the liability of losses occurring in handling gold slime is much greater than in handling amalgam.

I therefore propose bringing forward a few suggestions with the view of evoking discussion on the subject—too long neglected—so that the engineers who design these plants may have a fairly definite idea of what is really required.

The clean-up floor should have a drainage separate from the rest of the extractor-house floor, so that any washings shall not be contaminated with oil and grease from the pumps, etc., and may be run into a sump from which the residue, after settlement, may be easily collected and included in the next clean-up. Means of transport of the gold-bearing zinc, etc., from the extractor-boxes to the acid-tubs should be somewhat better than those afforded by the proverbial Kaffir and a bath or bucket. Much time and also labor is wasted by that method. An overhead crawl with tipping buckets could, I imagine, be easily installed in most plants and would soon pay for itself by the saving of time and labor, not to mention the decrease in liability of having gold slime accidentally split on the extractor-house floor, whence it is apt to be carried by the traffic to the outside of the building and lost.

The acid-treatment plant is often totally inadequate for the proper dissolving of the zinc and insufficient allowance made for the washing of the gold slime before filter pressing. I find it better to have two acid-treatment tubs of a certain capacity than to have only one of the same total capacity, as, when two are in use, one may be fed while the other is suffering from a threatened attack of 'boiling over,' while, when only one is installed, nothing can be done until the attack has succumbed to the 'cold water cure.' A stoppage at the acid-tubs throws back the whole clean-up, and the time thus lost cannot be made up.

When filter-pressing is begun I have always found that it may be much more quickly accomplished when the gold slime is drawn from the bottom of the washing vat than when the suction from the filter-press pump is slung over the side of the vat. As the gold slime is very heavy, it is advisable to use a specially short length of hose for the filter-press pump suction. If, when running down the charges from the acid-treatment tubs, everything is put through a 64-mesh screen and the contents of the washing vat kept in agitation while the press is being filled, there is no danger of the rose over the suction drain-pipe becoming choked.

The use of filter papers over the cloths of the press is also to be recommended, as filling is thereby facilitated and the life of the cloths is prolonged, as no scrubbing is required to clean them.

The filter-presses supplied have invariably, in my experience, the openings to the hollow frames left rough cored and with a quantity of fused moulding sand blocking the passages. By having these openings filed out so that the combined area, in a full press, is equal to or greater than that of the filling channel and with a slight increase of area toward the inside of the frames, there will be less liability of their choking, and the press may be filled in about 30% less time than when they are left rough.

For washing the cakes while in the press it is advisable to use hot water, not only for its better washing effect, but also because the cakes can be got out dry, even if there is only a layer of gold slime on the papers or cloths. A 400-gal. tank placed over the flue of the calcining furnace, if the latter is fairly close at hand, so as to utilize the heat from the escaping gases, will generally be found capable of giving enough hot water.

It is essential that a vat large enough to take all the washes from the washing vat and the filter-press be installed, so that the washes may receive further treatment before being run to waste.

Gold has been found to be present in solution in the acid washes. This is apparently due to the presence of hydrocyanic acid. The more completely the acid treatment is carried out, that is, when no zinc is left undissolved, the more danger there is of gold being redissolved. It is therefore advisable to have the washings slightly acid and then sprinkle zinc fume over the surface, meanwhile keeping the solution agitated. This should be done each time a charge from the acid-tubs is transferred for washing. After the clean-up is over it is advisable to have the contents of the large vat for the washings assayed, after good settlement, and, if necessary, more zinc fume can be added before the solution is run to waste. By this means the gold in acid washes run to waste may be reduced to 0.07 dwt. per ton, whereas the ordinary acid washes will probably carry 1.5 dwt., or more per ton. Copper sulphate, finely divided iron, and charcoal were also used for this purpose in the laboratory experiments, but, as zinc fume gave the most satisfactory results, it was tried on a working scale with such success that it has been used on all the mines of the Consolidated Gold Fields group ever since a supply could be procured. It is prepared by the distillation of zinc *in vacuo* and should be packed in air-tight cases, as it oxidizes readily on exposure to the atmosphere and is afterwards, of course, useless for this purpose. From five to seven pounds are sufficient to treat washes amounting to about 100 tons.

For taking off the acid washes from the washing vat it is advisable to use a decanter. If the arm of the decanter be painted white, the operator can see at a glance whether the solution is clear enough to draw off or not. The paint will last through a clean-up and can be easily renewed. The washing-vat may have a false bottom of cement sloping toward the outlet to enable it to be more easily cleaned out. The cement should be painted over with P. & B. acid-proof paint after each clean-up. If this is done it will show no signs of wear. When the paint is being applied it is as well to keep an eye on the person doing the job, as I have had a Kaffir overcome with the fumes from the paint when at work on the bottom of a vat 10 ft. deep. He quickly recovered on being taken to the fresh air.

Stirring gear for the acid-dissolving tubs should be installed, but the motion should be reversible, as it is often found expedient to reverse the direction of stirring in order to help the dissolving of the zinc and to free any which may have collected round the upright carrying the paddles.

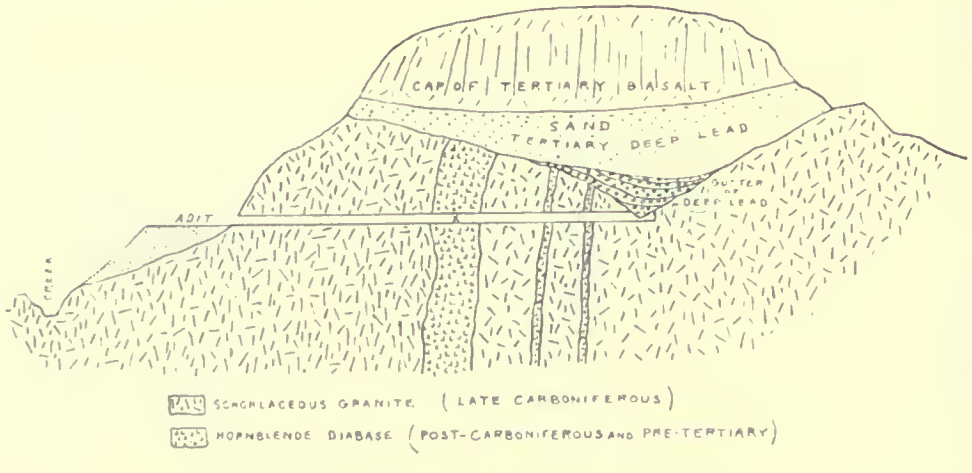
*Abstracted from *The Journal* of the Chemical, Metallurgical & Mining Society of South Africa, October, 1906.

In the miners' changing rooms at one of the German collieries (Shamrock-Westphalia) each man is allotted a place and is provided with a hook and pulley near the roof, and a rope by which he can pull the hook up or let it down. On arrival he lets down the hook with his mining clothes, changes, and hoists up his home clothes to the roof, then padlocks the end of his rope so that no one can disturb them.

The Occurrence of Diamonds in Matrix at Oakey Creek, Near Inverell, New South Wales.

Written for the MINING AND SCIENTIFIC PRESS
By T. W. EDGEWORTH DAVID.

Recently four diamonds have been found in the original rock matrix in which they grew or crystallized at the above locality. The discovery is interesting from a scientific point of view, and may yet prove of economic importance. Hitherto diamonds have been found in their original rock only in two parts of the world, namely, South Africa and Brazil. In South Africa the diamonds occur in great numbers in a matrix of a basic volcanic breccia in numerous volcanic necks or pipes. In Brazil a single specimen of gneissic rock was found some years ago containing a diamond in matrix, but unfortunately the specimen has now been lost, and no similar ones have been subsequently found. Now for the third time diamonds have been found in rock matrix, in this case in the State of New South Wales, Australia. The discovery was made by two miners, Messrs. Pike and O'Donnell, at Oakey Creek, about 20 miles from the town of Inverell. At the time they were engaged in driving a tunnel through the hillside in order to penetrate the rim rock of granite, which formed one of the boundaries of a deep lead (capped by basalt) of stream tin and alluvial diamonds. In driving the tunnel three dikes of hornblende-diabase were intersected in the granite. These are all nearly vertical and are strongly intrusive into the granite. The dike-rock is dull greenish black in color and, at first sight, resembles serpentine. The first dike struck was 26 ft. thick, while the other two were much thinner. In the very centre of the first dike a diamond about half a carat in weight was found to be imbedded in the solid eruptive rock. The scene of the discovery was at once visited by E. F. Pittman, the Government Geologist of New South Wales, who, as the result of a searching investigation, was quite convinced as to the genuineness of the discovery. Three more small diamonds were subsequently picked out of the more decomposed portion of the diabase dike, after it had been exposed for some time to the action of the weather. One of these is specially interesting, as it exhibits on its surface comparatively deep corrosion hollows filled in part with portions of the matrix of hornblende-diabase.



Daimantiferous Pipes Near Inverell, New South Wales.

This specimen, together with that of the diamond still *in situ* in the matrix, was exhibited by me to the Geological Section of the British Association for the Advancement of Science, at their recent meeting at York, England, last August. All unanimously agreed as to the absolute genuineness of the discovery. Sir William Crookes, Professors Bonney, Miers, Boys, Grenville Cole, Doctors T. H. Holland, and J. J. H. Teall, Directors of the Geological Survey of India and England, respectively, closely examined the specimens and discussed the mode of origin of the diamonds. Sir William Crookes thought that these Inverell diamonds had probably been formed originally under absolutely non-oxidizing conditions, such as would prevail if the surrounding material had been metallic iron. He pointed out that diamonds had already been found in nickel-iron in the case of the Cañon Diablo meteorite of the United States. He also referred to Moissan's experiments in Paris, which had resulted in the successful artificial manufacture of microscopic diamonds by the action of metallic iron on carbon, the melted iron, with carbon in the form of sugar charcoal dissolved in it at a high temperature, being cooled in such a way as to set up an immense pressure on the carbon when the latter was in the act of solidification.

The following arguments were brought forward in reply to Sir William Crookes:

1. Dr. Friedlander, of Berlin, had succeeded in manufacturing microscopic diamonds, not by means of metallic iron, but by means of a magnesian iron-silicate—olivine—in chemical composition not very dissimilar to the hornblende-diabase of Inverell. He had formed his small diamonds by stirring molten olivine with a small stick of black lead pencil. Dr. Friedlander's experiments had been amply verified, and they proved that diamonds could be formed under conditions where, as in the case of the silicates, oxygen was present.

2. Diamonds had been found in the Novo-Urei meteorite of Russia, and this was not an iron meteorite, but one largely formed of silicates.

On the whole, the general opinion seemed to be that the hornblende-diabase might very well be the original matrix rock of the diamond in New South Wales, and it was not necessary to assume that the diamonds had in the first case been formed deep down beneath the earth's crust in masses of metallic iron which had subsequently been dissolved in the hornblende-diabase. At the same time the strong corrosion of the surface of one of the diamonds proved that it had been floated up from some depth below in the hornblende-diabase and had suffered corrosion in transit, much as the crystals of quartz in a rhyolite lava show evidence of having been corroded by the matrix in which they are enclosed.

These specimens of Inverell diamonds were also exhibited by me at the International Geological Congress at the City of Mexico last month. Dr. Friedlander, of Berlin, was present on the occasion, and thought that the hornblende-diabase of Inverell was the original matrix of those diamonds.

Up to the present about 80 tons of material from the hornblende-diabase have been examined, with the result that only four small diamonds, whose aggregate weight is only about two carats, have been discovered, so that the discovery has so far not led to a remunerative industry.

Messrs. Pike and O'Donnell are now prospecting neighboring dikes in the hope of discovering portions of them in which the diamonds may have been more concentrated than they have proved to be in the original dike.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

A deed conveyed an undivided interest in the Slap Jack mine, and another deed described a mine known as the Jim Blaine mine, located by W., the boundaries of which coincided with the Slap Jack mine. The grantee in these deeds executed a mortgage in which the property is described as the Jim Blaine mining claim, being the same property located by W. on January 1, 1899, "of record in book 10, p. 271 Quartz Claims, Tuolumne County Records." After the execution of such a mortgage it was determined that the location of the Jim Blaine mine was ineffectual and that the deed to the mortgagor to such mine conveyed nothing. But it was held that the description in the mortgage was sufficient to pass the interest acquired by the mortgagor in the Slap Jack mine. The court said that the description used in the mortgage was intended to identify the property mortgaged by reference to documents which referred to the same property as was referred to in the deed of the mortgagor; and as the Jim Blaine mine embraced precisely the same ground, there could be no mistaking the intention of the mortgage to include this ground; that the purpose of the description of the property mortgaged or deeded was to identify the property, and not to indicate the source of the title; that property in a deed or mortgage may be sufficiently described by appropriate reference to any duly recorded document or public record containing the required description, and that proof of the description was completed by the introduction in evidence of such document or record.

Wemple *v.* Yosemite Gold Mining Co. (Cal.); 87 Pac. 280.

It was decided that a mining claim was not subject to the location by the complainant on the ground that the adverse parties, who were prior locators of the claim, had failed to do the required amount of assessment work for a certain year, where it was shown that such required work was not completed for the reason that the complainant had caused the servant of the prior locators to quit work and leave the claim by threatening him with arrest if he continued the work. The court said that a locator was entitled to protection in the possession of his claim, and could not be deprived of his rights by the tortuous acts of others; nor can an intruder or trespasser initiate any rights which would defeat those of any prior locator; that the complainant was an intruder and trespasser, with actual knowledge of the locator's possession; that he intended to and did prevent further work of the locator. The court applied the maxim that no man can take advantage of his own wrong, and stated that on this maxim rested the rule that he who prevented a thing from being done should not avail himself of the non-performance he has himself occasioned. The court in this case declined to follow any decisions which held or seemed to hold that the prior locator in such instances should persist in his efforts to perform the required work until prevented by the apprehension of imminent physical violence.

Garver *v.* Elder (S. D.); 109 N.W. 508.

The failure of the first claimant to complete his location after posting his preliminary notice inures to the benefit of a junior locator whose claim is in conflict with such older claim, when the inchoate right acquired by the discoverer and the posting of the notice never became fixed by a completion of the location.

Helena Gold &c. Co. *v.* Baggaley, (Mont.) 87 Pac. 455

The constitution and statutes of the State of Pennsylvania make all railroads, public highways, and railroad companies common carriers; and under the constitution and statutes, the Court of that State held that the owner of coal-mining property adjoining the right of way of a railroad was entitled as a matter of right, to connect the switch tracks built on his own land with the tracks of a railroad company in order to facilitate the loading and shipping of coal.

Olanta Coal Mining Co. *v.* Beech Creek R. Co., 144 Fed. 150.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The rock from Kokomo, Colo., is Quartz-feltzite with dendritic stains.

The mineral from B. F. W., of Battle Mountain, Nev., is black Hematite, the oxide of iron.

The mineral from J. C. W., Prescott, Ariz., is Wulfenite (molybdate of lead) with Vanadinite (lead vanadate).

The grayish mineral from T. C., of San Francisco, is simply Quartz colored with a little carbonaceous material.

The mineral specimen from Eureka, Nev., marked J. P., is Limonite coated with crystals of ferruginous quartz.

Rocks from G. M. & T. Co., of Oregon, are: No. 1 contains manganese oxide; No. 2 is Rhyolite; No 3, Rhyolite tuff.

F. C. D., of Sierra county, Cal., has sent: No. 1, Talc schist; No. 2, Gneiss or schist altered to a mixture of talc, serpentine, and clay, with some limonitic stains.

The specimens from N. Yamhill, Ore., are: No. 1, Feldspar-porphyry; No. 2, decomposed volcanic rock with malachite stains; No. 3, Rhyolitic tuff containing pyrite.

The rocks sent by J. W. A., of Los Angeles, are acid volcanics and are slightly different phases of the same rock, namely, rhyolite or rhyolite porphyry. The ore specimens are mostly brecciated rock stained with green malachite (copper carbonate) and crysocolla (copper silicate).

MALAY TIN OUTPUT.—The following table gives the output of all the tin-bearing States of the Malay peninsula for the first nine months during the years 1905 and 1906, expressed in tons of 2,240 pounds:

	1906.	1905.
Perak	19,271	19,740
Selangor	11,975	12,889
Negri Sembilan	3,452	3,738
Pahang	1,515	1,502
Total	36,213	37,869

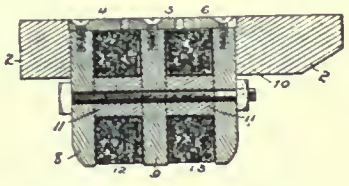
According to the market reports of shipments from the Straits Settlements for the first nine months of 1906, there was shipped 43,262 tons, or 7,049 tons more than the reported output of the mines. This shows conclusively that there was a large amount of tin on hand, held back to control the market and take advantage of the higher prices that have prevailed recently.

EDUCATION is from its very nature never complete, for the variety of natural phenomena is everywhere endless, and education (in so far as its goal is the mastery of these phenomena) must also be endless. An education which claims for itself completeness characterizes itself at the outset as a sham education. A completed education appears possible only when one restricts it to a very narrow field, and arbitrarily shuts out everything beyond this field as not belonging to education. The application of this statement to concrete cases may be left to the reader.

MINING AND METALLURGICAL PATENTS.

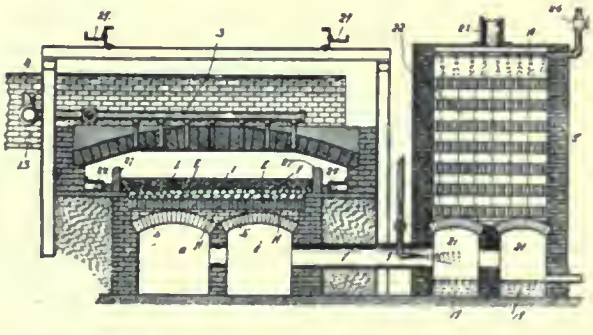
Specially Reported for the MINING AND SCIENTIFIC PRESS.

MAGNETIC SEPARATOR.—No. 837,994; James C. Winder, East Point, Ga., assignor to E. Van Winkle, Gin & Machine Works, Atlanta, Georgia.



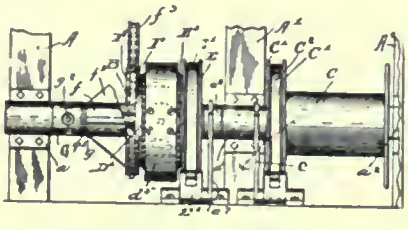
In a magnetic separator, the combination with a support of non-magnetic material having slots, and three magnetic bars spaced apart and sustained by said support, of a magnet comprising three plates projecting through the slots in the base and secured respectively to said strips, thimbles separating said plates, helices wound on said thimbles to energize the central plate with one polarity and the end plates with the opposite polarity, and means securing said plates, thimbles and helices together.

POROUS-HEARTH FURNACE.—No. 839,064; John E. Greenawalt, Denver, Colorado.



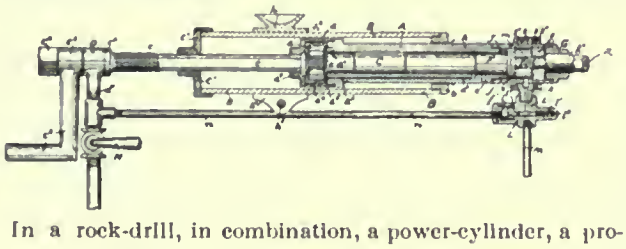
In a furnace for treating ore or other material, the combination of a porous bed or hearth, and means for passing air or gas downwardly through the material and the hearth upon which it rests.

HOIST.—No. 838,655; James R. Sharp, Chicago, Illinois.



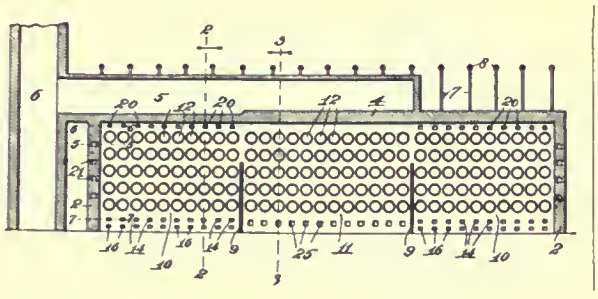
The combination with a drum-shaft of a drum thereon, a friction-brake engaging the drum, a gear-case rigidly secured on the shaft, a plurality of beveled pinions engaged therein near the periphery and projecting beyond the faces of the wheel, a continuously driven sprocket rotative on the shaft, a beveled gear thereon positively engaging said pinions, a controlling-gear on said shaft meshing with said pinions and a friction-brake therefor whereby retarding of the controlling-gear acts to rotate the shaft at a rate dependent upon the retardation.

ROCK-DRILL.—No. 839,586; Henry Hellman and Lewis C. Bayles, Johannesburg, Transvaal.



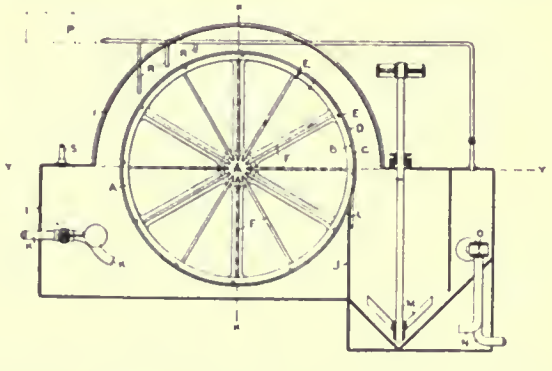
In a rock-drill, in combination, a power-cylinder, a protecting-casing in which the power-cylinder is slidably fitted, a reciprocating piston arranged in the cylinder, means fitted in the forward end of the cylinder for supporting the drill-bit so that the same has longitudinal movement in said means, means for rotating the drill-bit in unison with the power-cylinder, and means for advancing or receding the power-cylinder in its protecting-casing substantially as described.

ZINC-SMELTING FURNACE.—No 839,160; William Lanyon, Iola, Kansas.



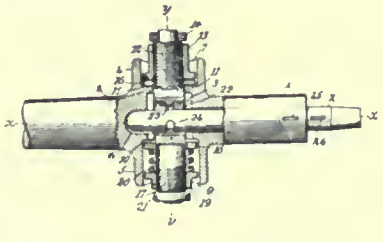
A zinc-furnace, constructed with a centre wall in which is formed a flue, means whereby air and gas are delivered into the ends of said furnace, and means whereby the air and gas during combustion are caused to pass upward between the retorts in the ends of the furnace, downward between the retorts in the centre of the furnace, and thence outward through the flue in the centre wall, substantially as specified.

CONTINUOUS FILTER FOR SLIMES, SANDS, &c.—No. 839,591.—Erle S. Huntley, Coolgardie, Western Australia.



A filtering apparatus comprising an air-tight chamber, a rotary member therein having filtering material on its outer surface, means for supplying air under pressure to said chamber and means for withdrawing the filtered material from the said rotary member.

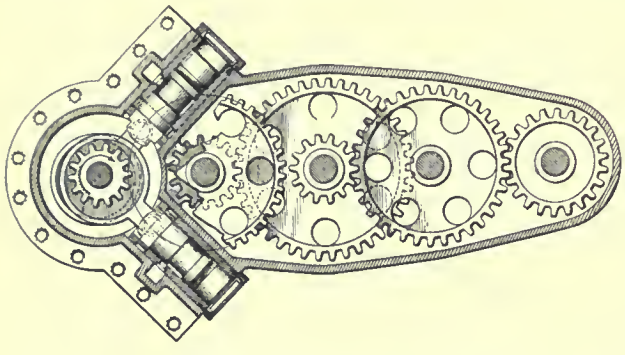
DRILL-CHUCK.—No. 838,638; Peter McKay, Day Dawn, Western Australia, assignor of one-fourth to William Hill and one-fourth to William Harrison, Day Dawn, Western Australia.



A drill-chuck comprising a tubular portion for receiving a drill or boring-tool, a chamber at the inner end of the opening of the tubular portion, a yoke or ring arranged in said chamber, an annular rib carried in said yoke or ring for engaging in a channel formed in a drill or boring-tool, threaded extensions from said yoke or ring, a clamping-nut on one of said threaded extensions, a nut on the other said extensions, and a spring surrounding said other extension.

The Little Giant Corner Drill.

The Chicago Pneumatic Tool Co. has just manufactured a new drill for corner work. From past experience in air-tool practice, they are enabled to state that this new drill surpasses any other yet devised for drilling in close quarters and in corners particularly. This new tool weighs but 35 lb.; capacity 1¼ in. (but in emergency cases will drive 2 in. twist-drills with satisfactory results); spindle speed when



New Drill for Corner Work.

runnnig light 150 r.p.m.; under load with 80-lb. air-pressure, 100 r.p.m.; distance from end of socket to end of feed-screw when run down 5⅞ in.; length of feed 2 in.; distance from centre of spindle to outside of housing 1 5/16 in. In addition to the fact that it is the most powerful drill ever devised, weight considered, it possesses advantages over other designs of corner drills, owing to the spindle being driven by gears instead of a ratchet so as to insure steady and constant spindle movement.

Electrical Equipment for Iron Mines.

The new power-plant which Witherbee, Sherman & Co. are erecting on the Lake Champlain shore at Port Henry, New York, furnishes an interesting example of the application of electricity in mining. It is not generally known that the lower Champlain Lake region produces a goodly proportion of the United States annual supply of iron ore. The various shafts of this company alone yield from 500,000 to 600,000 tons of iron ore yearly, while with the new electrical equipment the ultimate output will be 1,000,000 tons.

Owing to the fact that the principal shafts of the mines are scattered over a large area, electricity has been found to be the most flexible form of power transmission and is almost universally used. Power for this purpose is generated at present both by water and steam. At Mineville there is a steam plant with a 750 kw. engine-driven generator, which supplies current at 3,300 volts for local distribution. This power is supplemented by two small water-power plants; a 300 kw. water-wheel driven generator unit at Wadham's Mills, and a 370 kw. unit at Kingdom. At Wadham's Mills, a Morgan-Smith water-turbine is used, operating under a 48-ft. head. Power at the Kingdom plant is furnished by a Pelton impulse wheel under a head of 290 ft., water being carried through a 32-in. pipe a distance of 1⅛ miles from the reservoir. These stations are situated about 11 mines from Mineville and deliver current at Mineville at a potential of 6,000 volts. This voltage, made desirable because of the saving in transmission, is stepped down to 3,300 ft. at Mineville and is used in conjunction with the 750 kw. 3,300 volt steam-driven machine to supply power at the various shafts. Induction motors are used for driving hoists, pumps, air-compressors, etc., operated at 25 cycles and 440 volts.

The power-house which is being built at Port Henry is six miles from the mines, and will be interconnected with the other sources to supply the increasing demand for power. The station is to be thoroughly modern, being built of monolithic re-inforced concrete. Steam will be generated by four 500-h.p. Babcock & Wilcox boilers, arranged in pairs on either side of a 175-ft. stack. The boilers are hand-fired, and coal is conveyed to each by a car on a track running the length of the building. This car is filled from an over-head hopper through a hinged chute. The hopper is filled by a vertical bucket-conveyor that carries the coal from a pit filled directly from cars outside the building.

The generating equipment comprises an 800 kw. Curtis steam-turbine generator, which will deliver current directly to the line at a potential of 6,600 volts and 25 cycles. The compactness of the vertical unit has permitted a remarkably economical disposition of machinery in the generating room. Space is left for the installation of a second turbine. The switchboard is placed in a gallery with a re-inforced concrete floor. On this floor is placed also the motor-driven exciter set, and space is available for two frequency-changer lighting sets. A supplementary exciting unit is provided by a 25 kw. horizontal Curtis steam-turbine generator. The entire electrical equipment for this power-house will be furnished by the General Electric Company.

Canda Tempered Steel Jaw-Plate.

The Chrome Steel Works, of Chrome, New Jersey, are placing on the market an improved wearing plate for the Blake type of rock crushers, consisting of a combination of forged and rolled chrome steel bars, (forming the corrugations) inserted into a backing of tough open-hearth cast steel. The plate is constructed by placing into the mould, side by side, the forged steel bars, forming the wearing face, and casting the soft steel back around these bars, interlocking and cast-welding the entire back of the

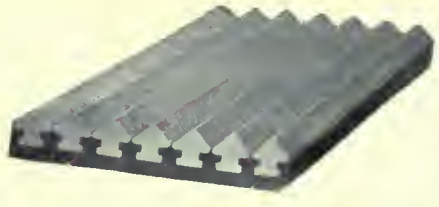


plate to the bars. The face of the plate is afterward tempered to the desired degree of hardness. By this method of construction, a plate of this. kind can be readily tempered, whereas if forged from one piece, it would be a very difficult matter to temper such a high-grade steel, without the plate breaking during the tempering process. The tough open-hearth steel for the backing is of such a low carbon that it does not take any temper whatever, thus a plate combining both extreme hardness and toughness is obtained. The accompanying illustration shows how the chrome steel forged bars interlock with the plate. These bars are finished in several sections, so that plates for any size Blake-type of crusher now in use may be conveniently constructed at moderate cost. The Chrome Steel Works are represented on the Pacific Coast by George W. Myers.

Commercial Paragraphs.

W. A. BUTCHART is resident manager for the Mexico Mine & Smelter Supply Co. at Mexico City.

A. LESCHEN & SONS ROPE CO. received an order for two hawsers and 300 ft. of patent flattened strand Hercules hoisting rope from the Arctic explorer, Lieut. Commander R. E. Peary.

The Tomboy Mining Co., operating at Telluride, Colo., recently placed an order with L. S. PIERCE, 1650 Champa St., manufacturer of the Pierce amalgamator, for one 30-ton, 17-riffle machine, and thirteen 25-ton, 25-riffle machines for use in their mill. The Smuggler Union mill has 13 of the Pierce amalgamators and reports the saving of several thousand dollars each month below the plates that heretofore was lost.

THE UTAH MINING MACHINERY & SUPPLY CO., of Salt Lake City, has secured the following orders from the American Smelters Securities Co., the machinery to be used in the new concentrator for the Nevada Consolidated Copper Co., at Ely, Nevada: Twelve 24-in. belt duplex Callow screens and 140 8-ft. Callow tanks, this order being in addition to the order for two screens and 68 tanks placed previously.

Editorial.

THE DIVIDENDS distributed in the United States during January are estimated to aggregate $206,000,000, a sum $50,000,000 larger than the previous best. Payments by railroads account for $51,279,602, as compared to $28,513,284 in the same month last year. But this does not include interest on bonds, which makes a further sum of $69,816,411. Industrial companies contributed $35,690,170 in dividends, an increase of $10,282,934; also $26,070,646 in interest on bonds. Traction and lighting companies are put down for $20,027,854, an increase of $8,014,353. Bank, trust companies, and similar corporations swelled the total. The figures afford eloquent confirmation of the prosperity of the country.

THE MINE MANAGERS of Western Australia, recently in conference, have been discussing seriously how best to encourage such successful prospecting as may compensate for the exhaustion of the big mines. It was proposed to give prospectors special privileges as to getting title to claims, remitting rents for the first year, and affording time to prove the character of their discovery. Monetary grants were deprecated, as having proved unsuccessful. All of which is interesting, but the best inducement to the prospector is the chance of a rich find and there is no incentive so powerful as the hunger for gold. A fair field and no favor is all the genuine prospector asks.

THE TENDENCY to exaggerate during times of speculative elation is shown by two statements appearing in the daily press this week. According to one of these Mr. Chas. M. Schwab has built "a huge mill in the Bullfrog district," this plant "will deal with 5,000 tons of ore a day" and "it is the largest of its kind in the world." It would be easy to make a bigger mill, for neither time nor money would be required, only a riotous imagination. The brutal fact is that the plant referred to will have a capacity of between 100 and 200 tons per day, and it is not yet completed. Another newspaper—a San Francisco daily—stated that "thirteen cars loaded with Goldfield ore, valued at $7,000,000" have arrived at Sacramento. Is it to be distributed among the members of the Legislature now in session? Apparently, they could find use for it. The fact is that the whole of Nevada produced $9,800,000 during the past year, and a shipment of $7,000,000 in one day would indeed startle the world. Goldfield is producing rich ore in quantity just now because the clean-up of the Mohawk leases is being marketed, but such childish statements as those quoted tend only to provoke suspicion of all news emanating from Nevada.

ANOTHER CHAPTER in the story of the Fresno Copper Company has been written, for the report of Mr. J. S. MacArthur has been published. By careful sampling, he finds that the body of pyrrhotite ore in the existing

workings averages 1.26 per cent, as compared to the 1.33 obtained by Mr. F. J. Siebert. But we are not among those that consider the lowest average necessarily the most correct and in this case it is to be noted that Mr. MacArthur's figure was reached by adding the average percentage on one level to that secured on the next and then dividing by two, instead of getting a mean figure based upon the proportionate quantity of ore involved in the calculation. However, Mr. MacArthur and his assistant took 600 samples, as against Mr. Siebert's 100, and in such estimates multiplicity of sampling is a factor of strength. It is fortunate for the shareholders and satisfactory from a professional standpoint that two engineers should arrive at a result so nearly identical. With the characteristic pluck of British shareholders, the Scotchmen who suffered by this fiasco have decided to sink the shaft and develop the mine. It is proposed to evade the smelting problem and to decrease the cost of treatment by adopting a wet process, that is, roasting succeeded by lixiviation, as is done in Spain. We do not know how much the people of Fresno want a copper industry in their midst and we are not informed concerning the feelings of the Fresno farmers, but we would advise the company to proceed slowly, for sulphur fumes are not properly appreciated by the agricultural population, and a brave effort to resuscitate a crippled enterprise may meet with scanty consideration at the hands of the surrounding community.

WE PUBLISH a plain statement concerning the working of the so-called 'black sands' in California. On a previous occasion we have deprecated the exaggerated expectations formed from certain experiments made by Dr. David T. Day, of the United States Geological Survey. In a circular letter sent out by the press department of the Jamestown Exposition, we note the following heading: "Fortunes in Sand Dunes. Deposits contain unrevealed wealth in precious metals and valuable ores Working plant at Jamestown Exposition to make analytical tests." We find by reading further that a concentrating plant is to be erected at the Jamestown Exposition, which is to test the gravel of placer deposits and the "pulp from deep mines." It is stated that "many of the gravel and sand deposits, besides precious metals, contain such minerals as magnetite, chromite, ilmenite, monazite, garnet, crysolite, zircon, quartz, etc., all of which have a decided commercial value. The results of these tests are invaluable, as was proved in the case of the sands of the Pacific Coast, and the precious metals and minerals discovered have been the means of developing several new industries." Concerning which we do not hesitate to say that it is absurd quackery and pseudo-scientific bunkum. Of course, the efforts of the Survey in this direction are well meant, but the work done at the Portland Exposition simply afforded the basis for a lot of fraudulent schemes and a mass of rubbishy writing concerning the untold wealth existing in a familiar type of alluvial deposit. We hope the farce will not be repeated at Jamestown. It is making the Survey ridiculous. In this connection we desire to express cordial agreement with our contemporary at New York, which says in a recent issue that the problem of rendering the black sand profitable "is an engineering problem rather than a geological or metallurgical," and for this reason it is best left to private enterprise, which will be quick enough to solve it if there is any money to be made. The Geological Survey will do well to keep out of such matters, which are beyond its proper scope.

The Production of Precious Metals in the United States.

Herewith we publish the statistics exhibiting the output of gold and silver in the United States during the past year, with those of 1905 to serve as a basis of comparison. Our authority is the Director of the Mint. It is necessary to explain further that the 1905 figures are the revised data published by the Director of the Mint late last year, while those for 1906 were furnished by him to the press on January 10. The Director, Mr. George E. Roberts, usually gives out preliminary estimates on January 1, and publishes a final statement about nine months later, when all the necessary corrections have been made. Last year his first estimates of gold production remained practically unchanged, but he modified those for silver, decreasing the total by 2,800,000 ounces and making one or two important changes of detail; for instance, Utah's yield was cut down from 12,000,000 to 10,319,800 ounces and Arizona's from 3,400,000 to 2,605,700. This year he gave two sets of preliminary figures, the first of these appeared in the columns of our New York contemporary. The total was therein given at $97,155,201 for gold and 57,358,267 ounces for silver. A week later came the figures that we now quote; in these the total of gold is about one million dollars less and that of silver 1,174,767 ounces less. The principal changes, as regards gold, are that California is credited with $500,000 more, while Colorado, Montana, and Utah get $800,000, $570,000, and $675,000, respectively, less than in the first estimate. This indicates that all the necessary data were not available on the first day of 1907 and that corrections were made almost immediately thereafter. This explanation has been deemed necessary to make clear the cause of discrepancies that otherwise would be confusing.

It will be observed that in 1906 the United States produced $7,920,700 more in gold than in 1905. The increase is due mainly to Alaska, with a gain of $6,325,000, and to Nevada, with a gain of $4,450,000. Arizona exhibits an increase of $530,000. On the other hand, there is a falling off in Colorado of $3,000,000, and in California, $500,000. It is most probable that the Alaska total is too high, for a great deal of the Klondike gold is shipped to the banks of Seattle and elsewhere, so as to be credited to Alaska instead of Canada. We expect to see a correction of at least $4,000,000 in the Director's estimate. Even allowing for this, there will be a handsome gain, which is due mainly to the Tanana region. At Nome, the building of ditches and systematic operations on a large scale are winning an output from the bench alluvium, so as to compensate for the diminishing yield from the beach deposits that made the locality famous. Nevertheless, it is probable that as hydraulicking enterprise

get under way in the Tanana country, the output of gold will make this region much the most important in Alaska. The dredges at Dawson ought to contribute this year. The increase in Nevada is less than the public expected, but the estimate is probably just, for the production of Goldfield was not augmented until the closing months of the year, and much of the richest ore was not marketed until 1907 had arrived. The present year, which begins with a great clean-up of the bonanza leases, will undoubtedly advance Nevada to the first rank of gold-producing States, and bring it more nearly level with the three leaders — Colorado, Alaska, and California. Colorado barely holds first place, and appears destined to be excelled by Alaska, for there is no reason to expect an increased yield from Cripple Creek or any of the older goldfields. In Colorado, gold mining is in a healthy condition, but no new districts have been discovered lately, so that the lower grade of the ore extracted tends to decrease the aggregate production, despite new enterprises that betoken vigorous development and the promise of profitable activity. Similar generalizations will hold true of California; the industry is prosperous, but the old districts are producing lower-grade stuff; alluvial mining is decadent save for dredging, the yield from which is increasing, but it is not much more than enough to offset the diminishing production from other forms of gravel mining. Copper mining is expanding, and the smelting of copper sulphides is stimulating the production of silicious ores containing gold; this factor is of some importance. South Dakota exhibits a steady output, but the bulk of it comes from the Homestake mine, and there is no evidence of any expansion in the gold mining industry. In Utah, the yield is estimated to be without change, for while the Bingham copper mines have been producing on a larger scale, and therefore yielding more gold, as a by-product, the purely gold mines, such as those of Mercur, have been retrograding. Much the same is true in Montana; a quarter of the output is won as an incident in copper mining at Butte; this contribution is fairly constant, but the gold extracted from quartz veins has diminished. Idaho is wonderfully prosperous just now, and the Cœur d'Alene region is being explored so vigorously that an increase is likely to be shown during the current year. On the whole, prospects are good for a further increase of gold production in the United States, for Nevada and Alaska will augment their yield appreciably, more than enough to balance any slight decrease in Colorado and California. It is likely that 1907 will reach a record of one hundred million dollars.

GOLD PRODUCTION.

State.	1905. $	1906. $
Alaska	14,925,600	21,251,100
Arizona	2,691,300	3,223,800
California	19,197,100	18,633,900
Colorado	25,701,100	22,771,200
Idaho	1,075,600	1,093,700
Montana	4,889,300	4,585,800
Nevada	5,359,100	9,815,800
New Mexico	265,800	255,900
Oregon	1,244,900	1,369,900
South Dakota	6,913,900	6,822,700
Utah	5,140,900	5,172,200
Washington	370,000	352,600
Other States	406,100	752,800
Total	88,180,700	96,101,400

In the mining of silver there is neither loss nor gain; despite an average price of 66 cents for the metal during 1906 as compared to 60 in 1905, the output remains stationary. However, there are some slight changes of detail. Montana produced 2,000,000 oz. less, for causes parallel to those that affected its gold yield. While the silver that comes from the copper ores of Butte has decreased slightly in amount, as did the copper in 1906, there was also a diminution from other sources, namely, the gold-silver ores. Colorado had a small decrease that balanced the gain of Arizona. Utah gained notably, as did Nevada; the first shows an increase of 1,240,000 and the second, 900,000 oz. In both cases this was due to the mining of another metal. The copper ores of Bingham contain precious metals, which are separated in smelting, and it is the growth of Bingham that is making Utah richer in silver. As to Nevada, it is too easily forgotten that the ores of Tonopah and Goldfield, like those of the Comstock, contain about as much gold, in weight, as silver. Therefore the silver output of Nevada may be expected to increase in 1907. Colorado remains at the head of the silver producing States, as she has been ever since the development of Leadville and the wane of the Comstock, twenty-seven years ago. In 1905 Montana for once was a little ahead, by reason of the by-product silver of Butte, but in 1906 the Butte mines yielded about 12,500 tons less of copper and this affected the silver output also. It is not likely that Colorado's production will increase; it is dependent largely on favorable smelting conditions, as they affect the low-grade fluxing ores of Leadville, Aspen, and Creede. The mining of low-grade ores in old mines is being stimulated by the rising price of silver and by the nursing of smelting conditions by the monopoly in Colorado. These are conditions that are not to be depended upon. It is likely that both Utah and Montana will exceed Colorado in 1907, for both get their silver mainly from a copper industry that is expanding, especially Utah. For these reasons we expect no increase in silver production during the current year.

SILVER PRODUCTION.

State.	1905. oz.	1906. oz.
Alaska	169,200	191,700

Special Correspondence.

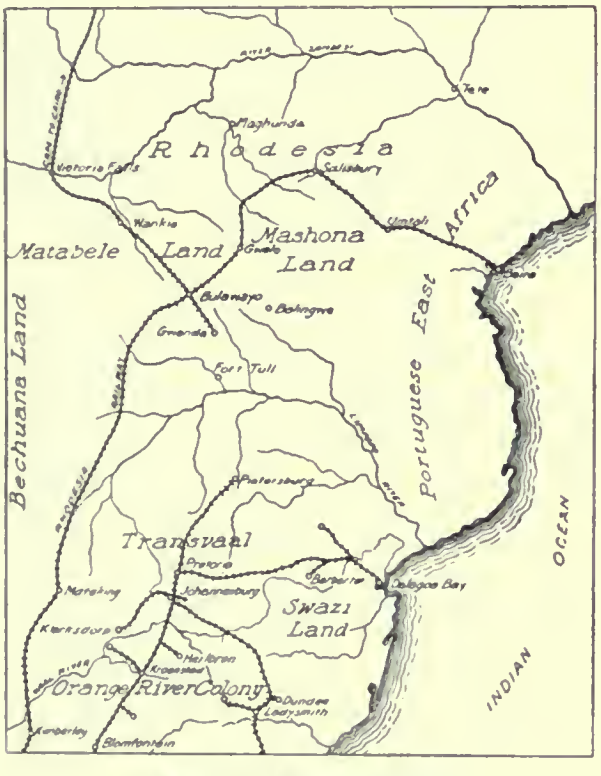
London.

Electric Transmission of Power.—The Victoria Falls Scheme.—Some Criticisms.—Siberian Gold Mines.—Cornish Tin Sales.—Esperanza's Output.—Shortage of Labor.

The closing weeks of the year have witnessed the accomplishment of a financial scheme in relation to mining at once bold in its conception and remarkable in the scope and magnitude of its proposed operation. Under the auspices of the British South Africa (Chartered) Co., the Victoria Falls Power Co. has been formed with a nominal capital of £3,000,000, of which there are one million ordinary shares and two million preference shares of £1 each; 625,000 preference shares have been issued at par. Subscriptions for an issue of £625,000 depentures at 95% have been guaranteed conditionally on the full allotment of the present issue. These depentures will form part of an authorized issue of £3,000,000 depentures, redeemable in 30 years at 10% premium. A strong board has been formed with the Marquis of Winchester at its head. Lord Kelvin heads the list of the advisory board of engineers. The company pays the African Concessions Syndicate £1,000,000 in fully paid ordinary shares and £120,000 in cash for the interests that it has agreed to sell and the Company will acquire the preferential right to develop 250,000 e.h.p. at the Victoria Falls and the exclusive right to deliver power from the falls to the Transvaal, for a period of 75 years. It also acquires as a going concern the plant and undertaking of the General Electric Power Co. at Driehook. It is intended to begin with 24,000 h.p., aud to extend operations at a later date. The Witwatersrand is described in the prospectus as "the market for power," and customers are ready directly the Company is in a position to supply them, and these include the Consolidated Goldfields Co., Eckstein & Co., and the Albu, and Lewis & Marks group. At Vereeniging, arrangements have been made with Lewis & Marks for the exclusive right to erect an auxiliary steam-driven station. The Falls Power Co. has bought up the existing Rand Central Electric Works, from which a determined opposition was threatened, the price having been fixed at £175,000 preference shares and £175,000 depentures of the new company. The main feature of the enterprise is described as the generation of electrical energy by hydraulic power at the Victoria Falls, and its transmission for the development of South African industries. In addition there will be a steam-driven station on the Rand itself, coupled with a system of hydraulic accumulation. This accumulation is to be accomplished by the extra power transmitted, over and above that which is actually consumed, being used for pumping water to a position where it will be accumulated and will be instantly available for reproduction of electrical power when required. With regard to the steam-driven station on the Rand, it is proposed to proceed immediately with the construction of a 24,000-h.p. station in a suitable position in the neighborhood of Johannesburg and the delivery of power from this station will commence in about two years. The hydraulic power at the falls will be developed by means of a canal, which will conduct water from a point on the northern bank above the falls, and deliver it at a convenient place near the top of the gorge at the first bend below the falls. The water will be taken hence by means of a series of steel ducts, fixed on the slope of the gorge, and delivered to a power-house to be erected near the water's edge some 350 ft. below. It is proposed in the first instance to install machinery at the falls for the production of 50,000 h.p. The main transmission line will be from the power station at the falls to a transmitting station near the Rand, and will probably follow approximately the course of the Rhodesian railway over the greater portion of the distance, some 700 miles. When the scheme was first ventilated in the press it was made the subject of severe criticism, inspired by rivals; but hostile voices have ceased to be heard since the settlement with Lewis & Marks in respect of the power site at Vereeniging, and with the Rand Central Electrical Works. As a forecast for future comparison, Robert Hammond's comment may be worthy of record. He says: "The transmission line, 700 miles in length, would necessitate such heavy expense for protection and maintenance that the company could not compete with supplies of power on the spot. Over 80% of the electrical energy produced at Niagara Falls is utilized within easy distance. It does not pay to use it in New York, which is only 480 miles away, and where coal costs much more than in the Transvaal. In order to ensure continuity of supply, the Victoria Falls scheme has to make duplicate and triplicate provision against breakdowns at huge expense and in face of great engineering difficulty. For the big supply of water required in connection with these provisions against breakdown the company will have to pay as high a price as 3s. 6d. or 3s. per 1,000 gal. Whereas the company itself seems to estimate that it can reduce the charge for energy in the Rand to 1.322d. per unit, it will be necessary to supply at less than one penny per unit to make it worth the while of the mine-owners to substitute electric power for steam-power." Sir A. B. W. Kennedy adds his protest on behalf of the Rand Central Electric Works (before it was bought out) concluding a long statement to the press by expressing the hope "that an engineer's view of the hopeless finance of the scheme, apart altogether from its special engineering difficulties and possibly fallacies, may perhaps prove a useful counter-active to the fascination which anything sufficiently big and sufficiently distant seems to exercise on the public."

One of the leading London companies operating in the Russian Empire, the Siberian Proprietary Mines, has issued its first report, covering the period from the inception of the concern on August 8, 1905, to November 30. The accounts show a "net profit on sale of mining options" of £422,657, and a credit balance to Profit & Loss of £417,097; while at the date of the balance sheet the company possessed £48,600 in cash. During the period covered by the report two subsidiary companies have been formed, namely, the Orsk Goldfields, with a capital of £600,000 in £1 shares, of which 500,000 shares, credited as 15s. paid, were issued to the Siberian Proprietary Mines as consideration for its services; and of these shares, 249,000 have been disposed of to the H. O. Siberian Syndicate "on terms which resulted in the whole of the issued capital being fully paid up without recourse to the available funds of this company." The other subsidiary is the Troitzk Goldfields, also with a capital of £600,000 in £1 shares, whereof 500,000 credited at 14s. paid, were issued to the parent company in payment for its services. As in the previous case, 249,000 of these shares have been disposed of to the H. O. Syndicate. The balance of 251,000 shares in each of these companies still held by the Siberian Proprietary Mines has been taken into the balance sheet at par, whereas the market quotation for the Orsk Goldfields issue is about 2½, and for the Troitzk about 1¾. The report gives details of numerous properties that the company is either working or investigating, and in order to carry out the program which the directors have in view, it is proposed to increase the capital from £100,000 to £135,000, by the creation of 35,000 new £1 shares, of which 16,000 are to be offered at a premium of £11 10s. to the existing pro-

prietors in proportion to their holdings. A glance at the balance sheet shows that notwithstanding the large balances of profit over £400,000, the Company's available cash is £48,600, little more than the total of premiums received on the issue of the Company's own shares. There is ample food for reflection in such a financial situation, as against the big premiums quoted for the parent company's shares, as well as for the shares of its two off-springs. Regarding these off-springs, the chairman gave some particulars at the annual meeting. It appears that the operations of the tributers on the Orsk Co.'s property for the past nine months have resulted in the milling of 12,225 tons of ore and an extraction of 6,694 oz. bullion, worth about 72s. per oz., exclusive of tailing, which probably contains one-third of the total gold. This does not serve to indicate what the Company will do when it settles down to work. The significance lies in the fact that the ore was derived from 12 different centres, from which a much larger tonnage will eventually be drawn. In addition to the returns as mentioned,



Map of the African Goldfields.

1,634 oz. gold were extracted from an alluvial deposit discovered since the property was taken over, and good results may be anticipated from this source when operations are resumed in the spring. Another alluvial deposit having been uncovered recently, improved returns may be expected almost immediately, as six new Chilean mills are in course of erection. Shaft-sinking at different points is reported. With regard to the Troitzk Co., work of a kind has been in progress on this property for a much longer period than at the Orsk. There are eight shafts sunk on the lode, with a varying depth of 300 to 450 ft., and the orebodies run in the deepest workings from 3 to 10 ft. Two main shafts in the eastern part are to be re-equipped forthwith, and sunk deeper as soon as more powerful pumping engines and machinery have been obtained. The main lode is proved for a length of more than 3,000 ft. The present workings are confined to a length of about 1,500 ft., but on the remaining 1,500 ft. tributers have worked to a depth of 100 ft., leaving the ore below untouched. A third new main shaft has been commenced on this portion of the property, and is already down 70 ft. Three lodes on an entirely new vein are being opened up on the Troitzk, and these at a depth of 150 ft. are reported to be in good ore, 5 to 10 ft. wide.

At the Cornish tin ticketing last week South Crofty, as promised, made a first appearance with a parcel of 18 tons. In a paragraph headed "Record Price for Dolcoath Tin" the *West Briton* remarks that the average price of the 259¾ tons sold this week at the ticketing at Redruth was about 12s. per ton lower than a fortnight before. The 65 tons of best tin from Dolcoath, in four parcels, sold at from £1 to 5s. per ton above the prices then made, this tin realizing from £122 7s. 6d. to £123 5s. 0d. per ton. The sale was one of the finest for a very long period in Cornwall, the total value of black tin sold in less than two hours being £25,452. Competition between the buyers was keen. Mines using magnetic separators did not realize such good prices as Dolcoath, Wheal Grenville, Levant, or West Kitty.

November returns from the Esperanza (Mexico) are as follows: The mill ran 27 days and crushed 11,590 tons of dry ore; shipped to smelter, 4,873 tons of dry ore; estimated realizable value of bullion produced, $129,317; estimated realizable value of concentrate, $50,718; estimated realizable value of ore shipped to smelter, $427,614—making altogether $607,649; receipts from rents and other sources, $299; total, $607,948. Working expenses, including development, marketing of bullion, and freight and treatment charges on ore shipped to smelter, $224,066; allowance for depreciation of plant, $2,500; consulting engineers' fees and New York office expenses, $2,945, making $229,511; profit, $378,437. Of this there has been expended on construction account, $1,093, and prospecting on Suceso property, $3,066; shipping ore on hand, 1,323 tons. The manager reports a shortage of labor during the month, which diminished the quantity of ore mined. The profit for November being considerably less than that of the previous month, the 'bears' claim justification for their prediction that the rich ore is giving out, and they say now that there will be a further "shortage of labor" in December to account for a still greater falling off in profits. Meantime genuine stockholders are enjoying the prospect of another quarterly dividend of 10s. 6d. per share declared for payment in January.

Cobalt, Ontario.

The Nipissing and the Guggenheims.—Opinions at Cobalt.—Delamar and Thompson.—Interesting Gossip.—The Smelting Situation.—Demand for a Canadian Smelter.—Value of By-Products.

The financial, mining, and atmospheric conditions at Cobalt seem to be improving daily. A rumor is current in the Camp that the Guggenheims have acquired the controlling interest in the Nipissing. Their paraded entrance followed by their mysterious exit has perplexed people here as well as the Canadian investing public generally and many theories have been advanced. Men coming from New York state that Capt. Delamar has disposed of his holdings in the Nipissing, which consisted of 168,000 shares, at an average of $17 per share and the belief seems to be general that the insiders have unloaded. In this connection it has been whispered that as an evidence of good fellowship some of their stock went to the Toronto end at $30 per share. The presence of Capt. Delamar in California, where he has been engaged for some weeks on litigation matters, coupled with the fact that much of the unloading was done through some banking houses on the Pacific coast gave the New York contingent an early intimation that he was selling. It is believed in Cobalt that the Guggenheims are now in control and that they secured the property at a much smaller price than that specified in their original option. It is also believed here that at least two of the original Nipissing holders have nothing to conceal. Col. Robert

Thompson, it is believed, sold his holdings outright at $22 per share to Capt. Delamar when the stock was being sold on the New York curb at about that figure and W. B. Thompson of the firm of Hayden, Stone & Co. is credited with still being one of the large individual owners. In any event the exit of Capt. Delamar is taken as indicative that the Nipissing will be properly mined and that the 'gouging' process will be discontinued. There is no doubt that the Guggenheim representatives, like nearly all the Easterners, came into the Camp with the idea that the Nipissing meant Cobalt. When they took the option on the block of Nipissing stock they believed that the expenditure of possibly an additional $3,000,000 would buy the district outright.

One of the stories current has been that Capt. Delamar had an option on a valuable Goldfield property which the great metal dealers were also after, and when they found that Delamar had the option they concluded that he was relying on his share of the plunder derived from the sale of the Nipissing and thought that by refusing to carry out their option they might hamper him sufficiently to give them a look-in on the property they were mutually anxious to acquire. It is well known in New York that the Nipissing insiders, as before stated, have pretty well sold out, Eugene Myers and Sam Newhouse being mentioned as the heavy purchasers.

The desirability of independent smelters is frequently mentioned in the Camp and W. A. P. Davis of Philadelphia is out strongly for such a proposition. If the people of the district pull together and the Government backs them up by an independent smelter, or by a vigorous supervision and watchful eye over the railways, so that there is no delay in the shipment of supplies and no harrassing of the mine owners, it is believed that the ore can be treated in Canada and the mine owners receive not only the silver value but also that of the by-products. Mr. Davis urges that the ores are at present treated in the same way that they have been treated for the past one thousand years and says that ore can be brought to Toronto cheaper than coal can be taken into the Camp, which will, beyond question, give operators an opportunity to handle the full values contained in the ore as against the present methods requiring loss to owners of the by-products.

To better illustrate, he says that the present purchasing basis for ores from Cobalt is 90% of the silver value alone. This means 90% of the price quoted per ounce on silver on the New York market. The output of the district will show by analysis at least 10% of cobalt, nickel, and arsenic. As the quoted price of refined nickel is 20 cents per pound; arsenic, 5c., and cobalt $2.50 per lb., it is obvious that the mine owners are losing heavily. On a purchasing schedule assuming the nickel, arsenic, and cobalt to be only by-products, a loss per ton can be shown of (on the basis of 10% of 2,000 lb.) 200 lb. nickel at say 20 cents; 200 lb. arsenic at, say, 1 cent, and 200 lb. Cobalt at, say, $1, making a total loss of $242 per ton. Ore now goes in carloads of 20 tons or upward, therefore, a loss is incurred of $4,840 per car. These facts have spread the idea that the ore cannot be properly treated on the American continent. This is a fallacy, for over a thousand years similar ores have been treated in Europe.

Smelting interests, particularly those identified with nickel and copper, have tried to depreciate the importance of the Camp and to depress the value of the mining shares, by the argument that the ores could not be treated. In one day, and on many days, there has been sufficient trading in one well-known stock alone to show that someone is trying to bring about this condition and the question may well be asked what particular interest would be ffected by the production of silver, nickel, and cobalt. Is there any reason for depreciation by the people that are now the principal traders in these metals? Is it possible for other than these subsidiary companies of the United States steel trust to secure nickel at a low price or even at a similar price to that maintained by the trust today?

It is claimed that Toronto affords an admirable site for the location of a new smelter. The labor conditions there are favorable, but the mine owners of Cobalt must unite in the support of any independent smelter, no matter whether it be built at Hamilton or Toronto. The statement is frequently made that the Guggenheims control the smelting situation and that they are directly or indirecely interested in every smelting concern in the United States where the ores of Cobalt can be treated, and that their object today is to control the output of the Camp as well as the plants where the ore can be treated. The present Minister of Mines for the Province of Ontario is a man thoroughly conversant with the conditions prevailing in the Sudbury district. It is a well-known fact that some of the mine owners at Cobalt believe that they do not receive the full values of their ore, but it is equally well-known that there are others who appear to be perfectly satisfied. The smelting situation is a difficult one and in these days of Government ownership of mines and Government ownership of railways in full operation in this Province, would it not be well to have a commission of experts take up the question of the advisability of either a Government smelter or of official encouragment to a Canadian smelter?

Johannesburg, Transvaal.

Eight-Hour Shift.— The White Labor Experiment.— Renewed Discussion.— Unskilled White Labor as Against Chinese.

For some time past there has been a good deal of discussion over the granting of an eight-hour day in the Transvaal. A few mines where the conditions are favorable have adopted the eight-hour shift. These mines are run with two continuous shifts of eight hours each, from 7 A. M. to 11 P. M., giving a period of eight hours for the mine to get cleared of smoke and dust. Because one or two mines are able to work the eight-hour shift, people are beginning to ask for a universal eight-hour shift for the Transvaal. But mines differ. It is quite possible to work the eight-hour shift on a well-developed outcrop property, where exploratory work has practically ceased, and there are a large number of working faces. In these mines the Kaffirs walk down the ladderway to the working places. With newly developed deep-level mines, the conditions are quite different, and it will be impossible to adopt the eight-hour shift without inconvenience and expense. This has become a popular cry, and although there will be considerable opposition, it is probable that there will be a universal eight-hour shift on the mines.

Verily this place is the artisan's paradise. He does less work and gets more pay for it than in most parts of the world. The unhealthy underground conditions are being improved every day, and now with an eight-hour shift, with the same pay, the artisan's lot should be a happy one. Were it not for the fact that the demand for skilled men is strictly limited on the Rand, the improved conditions of the artisan would no doubt attract thousands from all parts of the world.

A letter of great importance on the labor controversy on the Rand appeared in a local paper some days ago. There is a small minority here, lead by F. H. P. Creswell, formerly manager of the Village Main Reef mine, who maintain that the introduction of Chinese was not only a political crime, but not an economic necessity. This school maintains that by the increased use of un-

skilled white labor, and labor-saving devices, it is possible to work the mines as cheaply with the present supply of Kaffir labor, as it is to employ Chinese. Mr. Creswell tried what is known as the white labor experiment while manager of the Village Main Reef mine. For a long time he has been crowing both in England and this country about the great success of his experiment. A long letter from R. Raine, the present manager of the Village Main Reef mine, completely upsets his contentions. Mr. Creswell has been feeding the public on half-truths, which are more dangerous at times than untruths. From Mr. Raine's important document the following facts are taken: "Under Mr. Creswell the wage paid to the skilled worker on rock-drills varied from £11 12s. 4d. to £15 14s. 11d., not much more than a living wage. The white men were very discontented, and left the mine as soon as they found openings elsewhere. Consequently there remained a band of incompetents, which accounts for the high working costs obtaining when Mr. Creswell had charge of the mine, which varied from 25s. 4d. to 26s. 7d. per ton." Mr. Raine abandoned the policy of his predecessor altogether, and ran the mine along lines usually obtaining on the Rand, that is, with a limited number of white men and Kaffir labor. The average wage of the artisan on the Village Main Reef is now about £28, while the wage earned by the rock-drillers on stoping is from £45 to £50. Quite a difference from the £12 to £15 paid under Mr. Creswell's regime. There has been a great change in the class of men employed. At present they are a contented lot, doing as good work as on any mine on the Rand. Although Mr. Raine employs far less white men than Mr. Creswell, the total wages paid per month now is more than £2,000 than formerly. The costs have come down to 17s. 7d. This discussion has shown the impossibility of employing unskilled white labor on a large scale under the present conditions.

Butte, Montana.

East Butte.—Work Resumed in the Anaconda.—Progress in the Coeur d'Alene.—Mining Inspector's Report.—Amazon-Butte.—Zinc Companies to Consolidate.—Raven Shares Rise.—Production of Butte in 1907.

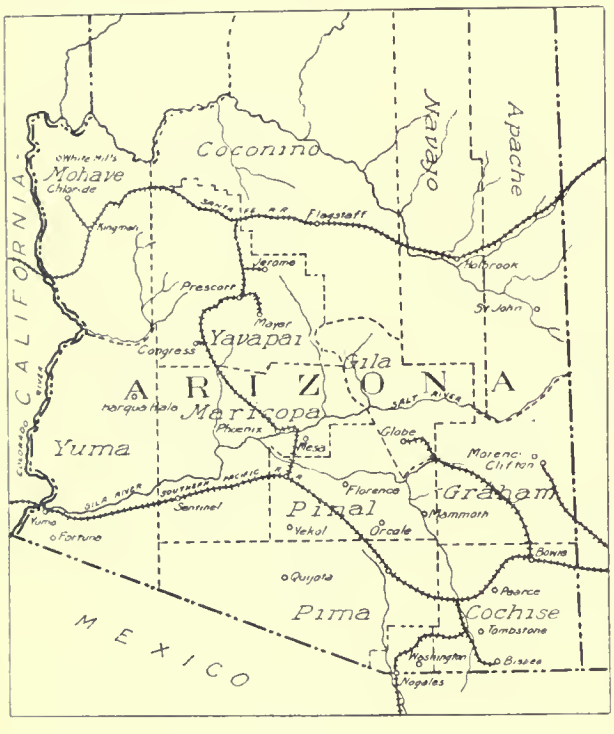
The East Butte Co. (Patrick Wall, general manager), has begun mining and shipping ore on its own account from the veins opened on the 400-ft. level of No. 1 shaft, and it is announced that the output is to be gradually increased. The earnings from this source will be virtually all profit, as the royalties from the lessees on the upper levels more than pay all operating expenses. The company has in excess of $100,000 in the treasury, and the profits from royalties during November and December amounted to about $25,000. No big shipment has yet been made from the company's copper precipitating plant, and about $12,000 worth of precipitate is on hand. The 600-ft. station in No. 1 shaft has been completed and sinking resumed. The shaft will be taken to 1,000 ft. before any further extensive cross-cutting is done. Shaft No. 11, at the southern extremity of the company's developed ground, is going down rapidly, and before long a cross-cut will be started north to connect with the cross-cut No. 1 at the 400. No work is being done in the latter cross-cut at present, as the company is awaiting heavier pumps in anticipation of cutting the big Glengarry vein. It is hoped to begin paying dividends during the coming summer. The big stockholders of the East Butte have so much confidence in the future of the company that they have withdrawn all their stock from the market.

Work has been resumed on the Anaconda mine, which was closed for a week on account of repair work and car shortage. Driving is being done on the vein at the 2,400-ft. level. Cross-cutting for the vein on the 2,400-ft. level of the Neversweat is progressing rapidly, and the company is also driving for the Belmont ground in order to connect with that shaft in the southern part of the district. The connection will result in good ventilation for the Anaconda mine, as the Belmont is a down-cast. The output of the Pennsylvania mine, of the Boston & Montana Co., has been increased about 200 tons of ore per day by utilizing a small engine to hoist ore from the 200 to the 300-ft. level.

A great amount of Butte capital is being invested in the Cœur d'Alene district of Idaho. Robert N. Bell, State Mining Inspector, says the district in 1906 shipped $22,000,000 worth of metals and paid $6,000,000 in dividends out of its few producing mines. "The sensation of the year," says Mr. Bell, "was the remarkable performance of the Bunker Hill & Sullivan lead-silver mine at Wardner. The enormous dividends paid from this property in 1906 probably stamps it as the most profitable metal mine in the West operated through a single entry and from a single orebody. The dividends for the year amounted to $2,340,000, in addition to which there has been developed in the mine within the past 18 months an entirely independent ore-channel, exposing the longest and largest shoot of mineral ever disclosed in the property. The other great silver-lead mines in the Cœur d'Alene are all continuing to show remarkable strength and improvement in their lower levels, and are all developing and opening up new levels at still greater depth. This unusual and interesting condition of permanency, together with the remarkable disclosure in the Snowstorm mine at Mullan of rich copper carbonate and sulphide ore, is the basis upon which an important boom in mining stock values and new development has been started during the year, and is now in progress in the Cœur d'Alene. The most important progress in Idaho's copper mining development during 1906 has been at the Snowstorm mine. This remarkable property has developed bonanza proportions during the past year, and with a light prospecting equipment produced shipping ore and concentrate to a total gross value of $1,200,000 in copper and silver, and paid nearly half of that in net profits. The ore-shoot shows a very indefinite outcrop high up on the steep mountain-side, and has been developed by three cross-cut adits to a total depth of 1,200 ft. Between the No. 2 and No. 3 adits there are four intermediate levels in which there is now blocked out 1,000,000 tons of ore of shipping grade. The shoot is over 600 ft. long and from 5 to 50 ft. wide. Where the sulphide ore is encountered it shows a pay-streak 12 ft. wide, carrying from 10 to 12% copper. The shipping ore, of which there was 80,000 tons sent to the smelters during the year, carries over 90% silica, 4 to 5% copper, and about 5 oz. silver per ton. There are a number of good copper prospects both east and west of the Snowstorm being actively developed at the present time."

A stringer of ore carrying both native copper and copper glance has been cut by the shaft of the Amazon-Butte Co. at a depth of 130 ft. The shaft is now 140 ft. deep, and the ground will probably be cross-cut at a depth of 200 ft.——The Butte & Arizona Co. has taken up the options it held on a group of copper claims in Arizona, the final payment of $50,000 having been made recently. Since the company has held the options, extensive development work has been done and several orebodies opened. The property is situated about 35 miles from Bisbee and the developments have induced the Santa Fe railroad to survey a line to within three miles of the mines, from which point a tramway will be built.

Plans are on foot for the consolidation of the Montana Zinc Co. and the Butte Copper & Zinc Co. Since the destruction of the plant of the Montana Zinc Co., that concern has had no asset except 7,500 shares of Alice mining stock, but the Butte Copper & Zinc Co. owns the Emma mine and some other mining property. On the Emma there is a shaft 800 ft. deep, and if the merger is effected the shaft will be unwatered and sunk deeper, and a large zinc plant will be built at the mine. ——The recent advance in Raven stock on the Boston curb has been in the nature of a surprise to the stockholders in Butte, for they have no information of a change in conditions in relation to the property. It is possible that the Eastern stockholders have agreed on some action since W. Spencer Hutchinson made his examination and report. There is talk about a possible consolidation of the Raven and the Old Glory Co. The latter owns some ground adjoining the Snoozer claim, of the Raven. When the Raven Co. was operating it used the Buffalo shaft of the Anaconda, worked through a cross-cut run through the Old Glory in order to reach the



Map of Arizona.

Snoozer, and mined on a vein claimed by the Butte & Boston Co. as apexing in the La Plata, a claim just north of the Snoozer. That was the peculiar situation when the Anaconda Co. took the Buffalo shaft from the Raven Co. and forced a suspension of operations about a year ago.

Mining men familiar with the situation say it is unlikely that the Butte district in 1907 will exceed the production of 1906, because last year every Amalgamated mine was pushed to its utmost capacity, and the high rate of production that prevailed all the year until hindred by cold weather, and by coal and car shortages, cannot long be maintained. "There is a limit to capacities of shafts and machinery," said an Amalgamated official, "and they were reached during the summer and fall of 1906. Every year makes mining in the big Amalgamated mines more difficult, and while they will be big producing mines for 50 years or more, it is not possible to increase their output much, if at all. On the contrary, it is argued, it is reasonable to expect a constant slight decrease in tonnage of ore. The North Butte Co. may increase its ore tonnage, but its copper output will not show a marked increase, for the average yield of copper per ton of ore is gradually decreasing, because the company is mining more of its second-class ore than it did when it first began mining. Its capacity for production was limited and mostly first-class ore was taken out. With increasing facilities, however, all the ore in the veins will be taken out. The North Butte may open another big mine in the Berlin, but it will be several years before that is done. The Clark mines will produce very much less copper this year than they did in 1906, because they are working in the lean copper zone. If there is to be any increase in the Butte copper output it will have to come from some of the new mines that are being opened by the Butte Copper Co., the Butte & London, East Butte, Butte & Bacorn, and such new companies."

Morenci, Arizona.

Shortage of Coal.—Flood on Chase Creek.—Damage to Railroad and Town.—Development of Outlying Claims.—Shannon Co. to Build a Railroad.—Stevens Group Bonded.—Prospecting for Oil.

At present the big mining companies of this district that are operating reduction works are threatened with a coal famine, the cause being the lack of transportation facilities. The Detroit Copper Mining Co. is now shipping all of its matte to the smelters of the Copper Queen Co., at Douglas, for treatment. They are also engaged in re-smelting the slag from their own slag-dump, in which the average run of copper is about 1½%. All the old converter ovens have been taken out and the ore and concentrate are now treated in the new furnaces higher up the hill.

The big flood on Chase creek on December 3 caused damage to the Arizona Copper Co. at Clifton to the amount of $165,000, mainly by washing out the Coronado railroad, a property of that company, which hauls the ore and concentrate from their mines at Metcalf, Coronado, and Longfellow, and the concentrators at Morenci. The road was not repaired sufficiently for haulage before December 15, and on this account the smelters of both the Arizona Co. and the Shannon Co. were forced to close down, and did not resume operations until January 3. Their concentrators No. 1, 2, 3, and 4 at Clifton were also injured by being partly washed away, and No. 5 and 6 were idle at Morenci on account of the lack of water, which is furnished them through a six-mile pipeline from the pumping station at Clifton. The Arizona Copper Co.'s smelter was filled with six feet of debris and tailing from the big dam at the bottom of the Detroit concentrator at Morenci. A large part of the town surrounding the works of the Arizona Copper Co. was injured or destroyed by the flood. The bursting of the big dam turned loose a large head of water filled with tailing. The disaster is also attended with loss of life. The people of the injured district have hired a lawyer and entered suit against the Detroit Copper Co. for damages of $150,000.

Work on the claims of the smaller companies that occupy the outlying country has been quiet lately on account of the bad weather. However, the managements of both the Home Copper Co. and of the Gold Belt Development & Reduction Co. have given notice of an increase in their working force immediately after the breaking of the cold spell. Both the companies have promising properties. There will be a meeting on January 8 of the directors and stockholders of the Gold Belt Co., and it is expected that the present board of directors will be re-elected, and the present management endorsed.

Reliable information states that the Shannon Copper Co. will build a broad-gauge railroad from their mine at Metcalf to their smelters and concentrator at Clifton. Contrary to the method followed by the Arizona Copper

Co. in building their line along the bottom of the cañon, the Shannon people have surveyed a line following the top of the ridge and will build the ten-mile track over the mountain. While it will necessitate much time and money to put this enterprise through, the Shannon company will be gainers in the long run in that their road will not be continually at the mercy of every little shower that comes down Chase creek, and at the same time they will avoid paying the heavy haulage charges of the A. C. Co. M. L. Amster, the new president of the Shannon Co., spent a few days at Clifton last week, and stated that on his return to the East he would take steps to start the building of this road. It is hardly probable that the Shannon Co. will put up the money to build this railroad, but it will be financed by Mr. Amster and other stockholders of the Shannon company. The new road should not only save money for the Shannon company, but it should also help to open up the Metcalf district to other companies now owning claims there; it would also afford an immediate outlet for the mines of the Detroit Copper Co. in that district, which are now being actively developed, as a junction could be made with the Morenci Southern, a Phelps-Dodge property, thus saving the necessity of carrying ore to Guthrie and transferring it to narrow-gauge cars for Morenci.

The owners of the Stevens group of mines in the Metcalf district have bonded their claims to an English syndicate, which purposes to develop this promising property.——A rotary drill has been put in operation by the Hot Springs Oil Co. at their prospect well south of Safford. The casing will be pulled out and the drill started, the hole being rimmed so that a 10-in. casing can be put down. The rotary has a capacity of 1,000 ft. per month.

Salt Lake, Utah.

News From Bingham.—Labor Troubles Settled.—Garfield Smelter Satisfactory.—Fuel Shortage.—Strike in the New Haven.—Fire at Fish Springs.—Lower Mammoth Connections.—Bingham Con. to Control Grand Central.—Dividends.

A strike of much importance to the future of the Bingham-New Haven mine has been reported officially. Ore similar in character to that found in the great Highland Boy mine of the Utah Con. has been encountered in the lower adit at a distance of 870 ft. The vein has been cross-cut for 128 ft. The upper portion of the mine has been productive of considerable lead-silver ore in the past. The directors of the company are considering the building of a smelter; at present the ore is shipped to the Salt Lake valley smelters for treatment.

The hoisting plant and shaft of the Utah mine at Fish Springs was destroyed by fire recently. It is believed that the fire originated from a lighted candle left in the shaft by a careless miner. The incident happened between the change of shifts. The regular monthly dividends will be disbursed, notwithstanding the mishap.——Connections have been made with the main shaft recently let down to the 1,700-ft. level of the Lower Mammoth mine in the Tintic district, exposing commercial ore for a distance of over 125 ft. The vein has been cross-cut, showing a width of between 15 and 30 ft. Two electric hoists will be installed, and regular ore shipments will be made. A site for the smelter to be erected in the Tintic mining district by the Tintic Smelting Co. has been selected near the town of Silver City. C. W. Nibley of Salt Lake is president. There is some talk of a consolidation being effected between the Swansea and South Swansea mines.

The management of the New England Gold & Copper Co., operating at Bingham, and controlled by Massachusetts parties, has effected a settlement of labor difficulties by granting employees an advance of 25 cents per day in wages.——The foundation for the new mill of the Markham Gulch Milling Co., at Bingham, is ready; it is expected that the plant will be completed early in the spring.——It is practically a certainty that the low-grade ores of the Ohio copper mine, which is now controlled by F. Augustus Heinze and Bingham Consolidated interests, will be concentrated at a point near the Dalton & Lark mine, and plans are being laid accordingly. It is the intention to extend the Mascot adit from the Dalton & Lark mine through the mountain to the Ohio orebodies. Heinze officials are of the opinion that no other Bingham company will be able to mine and treat ores more cheaply than the Bingham Con. and Ohio companies when they will have completed the development and equipment of those mines.

The management of the Garfield smelter of the American Smelting & Refining Co. has denied the report that

Utah.

some constructional and metallurgical defects have been encountered. In fact, the manager declares that the plant has behaved entirely satisfactory; that the only reason it has not been operated at its full capacity is due to the fuel famine, which has affected all the smelting companies operating in Utah. Two reverberatories and one blast-furnace are in operation at the present time. As soon as the fuel shortage is relieved the plant will be brought up to its full capacity. By the time the new concentrating mills of the Utah Copper and Boston Con. companies are ready to turn out concentrate, the Garfield smelter will be ready to receive it. The first unit of the Utah Copper is expected to be completed in May and the Boston Con. in July.

It is reported that Bingham Consolidated interests have secured an option on the control of the Grand Central Mining Co., also in the Tintic district. With the Eagle & Blue Bell, the Bingham Con. would then have mines that could supply silicious ores for many years to come.

So far this month, seven Utah mines have declared dividends, the total aggregating $1,123,000, as follows: Utah Consolidated, $900,000; Daly-Judge, $42,500; Beck Tunnel Consolidated, $40,000; Grand Central, $15,000; Victoria, $10,000; Utah, $3,000. The Silver King Mining Co., operating at Park City, has suspended payments temporarily owing to the fact that the company's funds will be drawn upon heavily to pay for the Magnolia-St. Louis property recently purchased.

Mining Summary.

ARIZONA.

GRAHAM COUNTY.

The Calumet & Globe Co. was recently organized at Calumet, Mich., to work four claims on Lower Pinto creek. The property was purchased from D. D. Sullivan and T. S. Collins. The directors are John Bertin, James Fisher, E. A. Peterman, and T. Carlon, of Calumet; Ed. Lieblein, of Hancock, and the two vendors, both of Globe. The company is capitalized at $300,000, in $5 shares.—— Sulphide ore has been cut in the Globe Consolidated on the 460-ft. level. The vein is three feet wide, and assays 5% copper. This company will build a road from its Gem claim to the foot of Buffalo hill, to connect with the Arizona Commercial railroad.—— In the Gray mine of the Old Dominion, rich ore has recently been encountered in the cross-cut from the 760 level, which has tapped the Nevada vein. About 40 tons of ore is being mined daily from this vein and shipped to the Old Dominion smelter.—— Low-grade ore, assaying about 4% copper, has been encountered in the second tunnel of the Pinto Creek Mining Company.

PINAL COUNTY.

(Special Correspondence).—The Central Mining & Development Co. has been organized to work eight claims in the Saddle Mtn. district, with S. H. Snider as president and S. D. Gardom, superintendent. The first discovery of rich gold ore in this group was made about three months ago on the Two Queens mine. The strike gave assays running into the thousands from picked samples, and a vein was disclosed from 4 to 12 in. wide for a length of 300 ft. Later development has given equally encouraging results. The first strike was sufficiently rich to make it advisable for a watch to be placed upon the high-grade ore to guard against theft. There are four parallel veins running the length of the property, each with numerous spurs. Thirty-four prospect openings have been made, all disclosing pay-ore. The silver content runs from 14 to 190 oz. per ton, and copper from 5 to 10%. Two tunnel-sites have been located, the ore to be delivered by a gravity cable to a mill, which will be built in the near future. The richest of the ore has been sacked until the company's reduction plant is in operation.

Phœnix, Dec. 22.

(Special Correspondence).—At a meeting of the directors of the Lake Superior & Arizona Copper Co., held at Calumet recently, it was decided to build the 28 miles of railroad necessary to connect the mine at Superior with the main line of the Santa Fe, Prescott & Phœnix Railroad, at Florence, and to erect a smelter of 250 tons daily capacity. The method of financing the company has not been determined upon, but it is estimated that about $500,000 will be required by the two enterprises. The new railroad will pass through an extensive gold and copper belt. There are about 300 miners in Superior. The town is well supplied with water, and the company contemplates the erection of an electric power and lighting plant. The company owns several claims here. A good strike has been made on the claim owned by J. I. Coleman and L. U. Riggins, situated near Troy. After sinking an incline shaft to a depth of 140 ft., an adit was started to tap the vein at a good depth below the bottom of the inclined shaft. This adit is now in for a distance of 200 ft., and at the breast a 4-ft. vein is exposed. This vein lies in a contact between quartzite and schist, and stands almost perpendicular.——At the Arizona-Hercules Copper Co.'s property at the west end of this mineral belt, diamond-drill exploration work is being done. Mr. W. P. Dunham, the principal owner in the company, is at the mine to superintend operations. This work is preliminary to active development. The Arizona-Hercules is situated near the Ray and Silver King mines, in which work is to be resumed during the month, the properties having recently changed hands. The new owners propose to unwater the Silver King, utilizing the old pumping plant, which is still in good order. They expect to find good copper ore below the third level.

Phœnix, Jan. 12.

YAVAPAI COUNTY.

The Bunker Hill mine in the Big Bug district, near Prescott, is increasing its force as fast as the men can be worked to advantage. The adit is being advanced toward the large bodies of gold and silver ore, prospected by shafts ahead. The main lode of the Bunker Hill mine follows the apex of the mountain for over a mile, showing a width of from 50 to 100 ft. in places, being joined and crossed by numerous veins that will be tapped at depth by the deep adit.

YUMA COUNTY.

The Pittsburg-Harqua Hala Co. took a working bond on the San Marcos group of claims in the Salome district, and has just made a first payment of $6,000 to the owners, John Martin of Harrisburg and Dr. Ancil Martin of Phœnix. The property is situated about 12 miles from the Harqua Hala mine. The San Marcos is a gold proposition upon which considerable money has been spent in development work. The deepest shaft is down 350 ft., while two others have reached a depth of nearly 200 ft. A second deal consummated by the Martin brothers in this district was the leasing of the Harqua Hala mine to Michigan parties, who were given a 99-year lease. The mill is now completed and ready to receive ore; 20 stamps will begin dropping as soon as fuel oil can be secured, a large tonnage of ore having accumulated in the bins.

News has been received from Salome of a rich strike on the Griffin property, located in the Harcuvar Mtn., under development by the Ironwood & Arizona Development Co., composed of the same group of capitalists owning the Harqua Hala mines. The details of the strike are meagre, but it is said that a large body of copper ore was uncovered in one of the shafts, the extent of which has not yet been determined by drifts or cross-cuts. The property has been under development by the Griffin brothers for several years. The mines are situated seven miles northwest of the town of Salome, in the foothills of the Harcuvar range.

CALIFORNIA.

CALAVERAS COUNTY.

Wm. F. Jensen and W. H. Hersh, of Chicago, Walter E. Patton, of Pittsburg, Pa., and Levi Johnson, of Osage City, Kansas, spent a few days in San Francisco on their return from a visit to the Hamby mine, near Mokelumne hill. This property has been equipped and is operated by the Viking G. M. Co. of Chicago, and its president, G. E. Engstrom, has been looking after the equipment. This includes a modern 20-stamp mill and Frue concentrators, operated by electricity, a 65-ft. gallows frame, a three-compartment shaft, with a steam-hoist raising ore from the 200-ft. level and automatically dumping it directly onto the grizzly and into the mill-bin. The mill started operation the last of October and is said to have made a creditable showing for the time it has run. The present stopes are said to be in a lode 19 ft. wide, and from all reports they have a typical low-grade free-milling Mother Lode proposition. About 30 men are employed, housed, and boarded at the mine. It is understood that the gentlemen mentioned above were here to consider the advisability of taking up the remaining indebtedness on the property, greatly increasing the mill capacity and doing a lot of underground development work in the near future.

ELDORADO COUNTY.

(Special Correspondence).—The Alpine mine has cut a good body of ore in the drift on the 300-ft. level, which is thought to be a new shoot.——Clifford Cheek has some ore showing in the Golden State, which was at one time a producer.——Nels Locke has a good prospect near the old Spanish dry diggings on the Georgetown road.——Little is being done in the copper belt east of Georgetown, but it is expected that the district will show up well with development.

Placerville, Jan. 9.

(Special Correspondence).—The River Hill Co. is preparing to sink its incline shaft from the 1,300 to the 1,500 level. This is the only deep mine at work on the Mother Lode, north of the Union, and it has been producing for some years. There is a drainage adit at the 735-ft. level. A 20-stamp mill is situated near the shaft, and an air-

compressor is in operation at the mouth of the adit. George Clark is the superintendent.——The Sherman mine has reached a depth of 500 ft., and has a good showing of ore. A small stamp-mill is running, producing a concentrate worth $200 per ton, besides yielding good returns from the plates. Tom Clark is manager. Several promising prospects lie near the Sherman.——The water company ran the old Excelsior mine for some years as a quartz mine, but it is now producing gold-bearing gravel, which was cut by extending the old adit 2,000 ft. Enough gravel has been exposed to keep the 10-stamp mill running for two years. The gravel is strongly cemented. The Gray channel has yielded some samples running from 50c. to $5 per pan. At the portal of the long adit an air-blast furnishes a good supply of air to the face 3,000 ft. away, through a five-inch pipe. The Blue channel has also been cut. This channel has been worked for several miles and has produced several millions of dollars.——The Live Oak Co., operating drift mines 2½ miles above Placerville, is working eight men, and running from 50 to 60 cars per day of cemented gravel through a Ure mill, which is similar to a Krogh mill. This output has been maintained for 20 months.——Bert Carpenter has reached the gravel in the old Blue channel, on his property, about two miles above Placerville. He is working the ground through an incline shaft.——The mining industry is prosperous around Placerville. Some good copper ore has been mined near Eldorado, and a good showing of copper is reported near Fairplay.

San Jose, Jan. 12.

NEVADA COUNTY.

There are no prospects of an immediate settlement of the strike at Grass Valley. The miners still insist on a straight eight-hour schedule, and the operators demand that the men go back to work under the old schedule, pending the consideration of their demand. They promise to return an answer within 24 hours after the men return to work. The miners' union holds meetings frequently, and state that they desire a settlement, but that they believe the operators had sufficient time to respond to their demands, before the strike was called. The effect of the continued idleness of the men is that miners are leaving the camp at the rate of about 20 per day. Arizona and southern Nevada are the destinations of the majority of the men. Several of the pumpmen have been temporarily granted an eight-hour day. Even an early settlement of the strike would leave the mines short-handed, as there was a scarcity of miners before the strike and every day the supply is decreasing.—— The New York-Grass Valley mine, locally known as the Perrin mine, has undergone an entire change of management, Chester B. Allen succeeding F. H. Johnston as manager of the property. The mill will not be started until a new hoist is erected.

(Special Correspondence).—The Yuba Mining Co., operating the Yuba mine three miles east of Washington, has secured a bond on the Blue Jay about eight miles east of Washington and adjacent to the Grey Eagle.——The contour of the country in that vicinity is such that a property can be explored by adits.——At the Baltic mine, eight miles northeast of Washington, a tunnel 1,400 ft. in length is being run to open the old Crown Point shoot, out of which many thousands of dollars were taken in early days. This property joins the Star and Ethel mines.——At the Red Cross mine, near Omega, preparations are being made to install a new hoist. As soon as the hoist is in place, sinking will begin. This property is equipped with a 20-stamp mill. ——At Camptonville, 25 miles northerly from Nevada City, there is great activity in mining.——The Consolidated Willows Mining Co. at Weeds Point has installed a $3,000 compressor. They are running a tunnel to tap the Horse Valley hydraulic mine, which is considered the best in the country.——The Joubert mine at the head of Willow Creek is now running full blast.——Jahon Meek will superintend the opening of the Brandy City mine; $40,000 will be expended to get water upon the property.——At the Trent Copper mine they are making good headway with the shaft. As this is the first attempt to develop any of the copper lodes in the district, the results are awaited with much interest.

Nevada City, Jan. 15

SHASTA COUNTY.

(Special Correspondence).—Grading on the smelter site at Heroult is now completed and the erection of the transformers for the electric furnace is being hurried forward. Bricks are being prepared for the charcoal kilns, and contracts have been let for cutting cordwood. This can be obtained from the adjoining hills for the present, and as the demand increases, a supply of logs can be floated down the Pitt river. Iron ore is being hauled for the trial run, on the completion of which an adequate means of transportation will be installed. The main orebodies are about one mile from the smelter site and 800 ft. above it. The new railroad under construction from Kennett to Bully hill will pass through the smelter yard.——The Mammoth Copper Co. is actively exploiting silicious fluxing ores by the construction of a railroad to the Quartz hill district, and the examination of several properties on the west side of the Sacramento river. A railroad is also to be built to transport ore from the Mammoth mine to the smelter at Kennett in place of the aerial tramway, which has proved costly and unreliable. The length of this tramway is about three miles. The grading for the trolley road to connect the Hornet mine with the Iron Mountain railroad is completed, and track is already laid on the railroad spur. The tunnel on the Iron Mountain railroad caved last week, but traffic was resumed after a steam-shovel and grading crew had worked a few hours.

Redding, Jan. 15.

The Bonanza King Co. expects to start its 40-stamp mill at once. The plant is complete, and the electric power station in order, after the expenditure of about $150,000.—— A recent strike is reported from Harrison Gulch. Samples from the outcrop assayed well.——The Midas mine is doing but little work at present. Good ore has been struck on the 700 level, but the mill is not running.——Many claims are being located in the Shasta copper belt, the recorder having recently received 135 notices of filing in one day.

TUOLUMNE COUNTY.

(Special Correspondence).—Good reports still come from the Blackhawk mine, situated two miles west of Soulsbyville. High-grade sulphide ore containing some free gold is found there. The shaft is 200 ft. deep, and from it drifts are being run on the vein.——The Goldwin Co. last week sold its 10-stamp mill to J. B. Menardi, of Reno, Nevada. The company does not intend to abandon the mine, and work will be soon resumed at the property. Several orebodies have been opened up, and the face of the adit where the last work was done is in ore of good quality. The vein at this point is about four feet wide.——The Dondero gravel mine at Yankee Hill, near Columbia, has been bonded to San Francisco capitalists, who are represented here by A. F. Dollin and J. Sherman of that city. The company proposes to install modern machinery and carry on operations on a large scale. ——It is reported that Lyon, Baum, and McFarland have sold a one-fourth interest in the Yorktown mine, situated on the Kline ranch, near Stent, for $20,000. The Yorktown is attracting attention owing to the unusually rich strike recently made near the surface. Each day's work has helped to verify the belief that this mine has a promising future. ——Thirty stamps are pounding on ore at the Harvard and ten more will soon be let down. Sixty men are employed. ——Twenty tons of ore from the Cosmopolite mine were milled recently, and the result is said to have been good.

Tuolumne, Jan. 8.

(Special Correspondence). — Los Angeles people have bonded the Garfield mine and will erect a 10-stamp mill on the property. A rich strike was recently made in the Garfield, and some high-grade ore is ready for milling.——The Mountain Mining Co., which is operating the Mary mine, situated north of Tuolumne, will begin work at the Prudhomme, in the same vicinity, shortly. Development work has been going on at the Mary mine for months, and it is one of the most promising of the new mining properties on the East Belt. W. A. Monroe is superintendent.—— The United Mines Co., which owns the Grizzly, Lady Washington, New Albany, and Dead Horse mines, is increasing its crew for development work. The machinery for the 100-stamp mill has nearly all been delivered, but owing to the unfavorable weather the erection of the mill has been

delayed. The ditch and flume, several miles long, have been completed.—— A new shaft is being sunk at the Parallel mine, situated near Soulsbyville, the old one having caved in since the mine was abandoned many years ago. The new shaft shows a vein of good ore 12 in. wide.—— At the Patterson, the winze in the south drift has been cleaned out and enlarged to a depth of 30 ft., and the work is still in progress. It is the intention to run a raise to the surface and sink to a depth of 400 ft., making a three-compartment shaft. The pipe-line will soon be completed and the hoist will be operated by water-power.

Tuolumne, Jan. 14.

COLORADO.

DOLORES COUNTY.

Rico's shipments for 1906 were about 6,000 tons, much of which was concentrate, with an average value of $135 per ton. The United Rico Co. led the production with 112 cars, the Wellington following with 81 cars, the Pro Patria 16, Swansea 10, Swickhimer two, Silver Swan two, and Gold Anchor, Bancroft, and McGill & O'Keefe each one car, totaling 227 cars.——The United Rico Co. elected D. H. Moffat chairman of the board of directors for the ensuing year, and A. B. Roeder general manager. The general offices of the company have been moved from Denver to Rico.

SAN JUAN COUNTY.

Work is being pushed during the winter months with gratifying results at the Bullion King mine, at the head of Porphyry gulch, immediately west of the Silver Ledge. The group embraces 17 claims and a millsite, seven of the claims being patented. The principal veins so far opened up are known as the Lake View, Oliver Twist, Bullion King, and Francis P., and the present workings are so directed as to tend toward the ultimate development of these main veins by one system of operation. These veins are strong and can be traced on the surface for miles, extending over the ridge and well down into San Miguel county. They vary from 10 to 50 ft. in width. The quartz is impregnated with copper and lead sulphides, carrying both gold and silver, and giving an average return of $10 per ton, and concentrating at the ratio of 5 to 7 into one. Arrangements have just been completed with the Animas Power & Water Co. to furnish power for the electric drills that are in use at the mine. The present force will be increased as soon as this connection can be made, and a mill built to handle the product of the mine. H. N. Timolat is manager, with A. J. Aurand as superintendent.——In Prospect basin, just over the crest of the divide, are situated the properties of the Iron Hat Copper-Gold Co. Development has shown up large and well-defined veins, the ore being mainly copper, carrying gold and silver. The breast of the adit is now nearing 350 ft. and several carloads have been shipped. On the opposite slope of Red Mountain, the Guston, Yankee Girl, Robinson, and Congress are situated—mines which have produced over $12,000,000 in the past. Arrangements have been perfected for keeping the roads open and free of snow all winter, so that work will be prosecuted on these properties with vigor, irrespective of weather.

IDAHO.

BLAINE COUNTY.

The Idaho Consolidated Co. has started work again on its property near Hailey. The shaft is down 70 ft., and electric drills are ordered, with which the shaft is to be sunk to the 1,000-ft. level. This company has purchased the Minnie Moore mine, and now has about 20 claims. I. E. Rockwell is the general manager, Sam Allen is the superintendent, and J. J. Donovan the chief engineer.——There has been a revival of mining in the Wood river district during the past year, especially at Galena camp and the Little Smoky region.

NEZ PERCE COUNTY.

(Special Correspondence).—The American Placer Mining Co., the stock in which is owned principally by J. M. Porter, of Spokane, has between 200 and 300 acres of workable placer ground seven miles from Pierce City, on which operations will be resumed next March. Last season the property was put in good condition for operation. A hydraulic elevator of the Ruble pattern was installed, and for the short time it was used it proved satisfactory. The Ruble elevator combines the grizzly, elevator, and undercurrent. A No. 2 giant, with 4-in. nozzle, drives the gravel to the elevator, and a second giant of the same size drives it through. While being elevated the finer sand and gravel, which carries the gold, is screened from the boulders, the valuable portion passing to an apartment having a tight, smooth, inclined floor, down which it is washed to the sluice-boxes and riffles. By actual test, 26 yards per hour were handled. Boulders 32 by 18 by 16 in. were elevated 22 ft. with a 4-in. nozzle, under a head of a little over 100 ft. Mr. Porter states that any boulders the field giant can drive to the elevator can be put through. This elevator is on rollers and can be readily moved.

Spokane, Jan. 10.

OWYHEE COUNTY.

Work on the north drift on No. 2 level of the Potosi mine at Silver City has been suspended, as the north drift on the Knickerbocker vein on the same level runs parallel to it and will explore the same ground. The south drift on No. 2 level is going ahead without any notable change in the character of the vein. Notice of shipment of power-drills and compressor has been received from Denver.——At the Banner a raise is being run from the cross-cut tunnel to the upper drift on the Webster vein. The vein has widened out, from a stringer in the tunnel to three feet in the raise. The completion of this will aid the ventilation and make it possible to start work on the cross-cut tunnel, which is now in 1,100 ft., and near the Banner ledge.

NEVADA.

ESMERALDA COUNTY.

The Goldfield strike has been settled, the miners having voted to accept the proposition made to them by the mine owners. The total vote cast by the miners' union was 1,847, and the number in favor of ending the strike was 1,293, 554 voting to reject the proposals of the committee. The proposition accepted is a $5 day for miners and skilled help, and $4.50 for laborers. A lively session on the Stock Exchange followed the announcement of the result of the balloting, and there is great rejoicing in the district.

LINCOLN COUNTY.

(Special Correspondence).—J. M. Albright has recently returned from the new copper strike 25 miles up the Colorado river from the mouth of El Dorado Cañon. Assays across five feet of the surface of the ledge gave an average value of 16% copper and $5 in gold. He secured these locations through an Indian guide. The only way to reach that section is by boat up the Colorado river from the mouth of El Dorado Cañon. After leaving the river everything must be taken in on packs, and the country is exceptionally rough. In spite of this the district is already filling with prospectors and when the weather moderates a camp will be established on the river and some regular means of communication installed between the new copper district and El Dorado Cañon.——Operators on the flat about four miles west of Searchlight have struck some rich ore in the shaft; samples assayed in Searchlight gave returns of $216 per ton.——An ore-shoot has been uncovered in the 200-ft. level of the Wyoming Searchlight Co.'s property, three miles west of the town. Mr. Carlston is manager of the mine. The apex of a good ore-shoot has been cut. The main shaft of the property is down 300 ft., and, as soon as a station is cut, a drift will be driven under the new strike.——G. W. Lloyd purchased during the past week the Esther group and also the Golden Calf in the northern part of the district. These properties adjoin the Florence group to the west, and have a good surface showing.——Fourth of July Mountain, four miles east of Searchlight, has the latest strike. In a tunnel on the Stanley Forbes a vein was cut which has a streak of ore about a foot wide that shows free gold.——The Searchlight Consolidated Co. is actively at work. The house for the superintendent has been completed and a 25-h.p. hoist ordered. The new shaft is down 40 ft. and the timbering nearly completed. As soon as the necessary accommodations can be arranged for the men, the company will put on another shift and sink the shaft to the water-level. The control of

this property has recently been sold to Philadelphia capitalists.——A contract has been let to sink 100 ft. on the Zodiac group west of the Quartette. This property has been acquired by A. M. Squires, of Los Angeles.——Development work is going on around the Wyoming Searchlight Co. A lot of surface prospecting is being done on the Big Eight group. The Golden Rod, which adjoins it on the north, has just completed a 50-ft. shaft, and a contract has been let to continue the same to the water-level.

Searchlight, Jan. 11.

NEW MEXICO.

SANTA FE COUNTY.

(Special Correspondence.)—Richard S. McCaffery, general manager for Lewisohn Bros., New York, owners of the Santa Fe Gold & Copper Co., expects to blow in the 200-ton smelter at Santa Fe, within a few days. This plant, which has been idle for some time, has been put in shape for treating ore from the mines of this company.

San Pedro, Jan 11.

OREGON.

BAKER COUNTY.

(Special Correspondence).—The plant of the Oregon Smelting & Refining Co., of Sumpter, operates only periodically, as it has a capacity of 150 tons per day, and the district does not supply a sufficient tonnage to keep the plant in continuous operation. R. B. Green is superintendent. The smelter has a 38 by 144-in. matting furnace that turns out a matte usually carrying 10 oz. gold and 60 oz. silver per ton, and 15 to 40% copper. It handles the high-grade ore and concentrate of the district, the bulk of which are dry ores, making it necessary to ship from Idaho the copper ore required in producing the matte. The ores from Cable Cove, however, are iron sulphides, and the mines at Quartzburg, including the Standard, Copperopolis, and Dixie Meadows, will in the future be able to supply a good tonnage of copper-iron sulphides. The steady shippers of the district comprise the North Pole and Columbia, both situated near Bourne. The Mountain View, Eureka & Excelsior, Bonanza, Elkhorn, California, Imperial, Buckeye, and others have made frequent shipments.

The E. & E., belonging to Johnathan Bourne, of Portland, is doing development work and making tests and experiments to solve its milling problem. The main shaft is 700 ft. deep, with drifts 500 ft. north and south from the shaft on the 700-ft. level. On the 500 level drifts have been run 1,500 ft. on the vein in opposite directions from the shaft. A similar amount of work is shown on the 400-ft. level. It is stated that the best ore found in the mine has recently been cut on the 700-ft. level. F. W. Bradley, of San Francisco, is consulting engineer for this property, with E. P. Kennedy in direct charge.

The Imperial, at Cable Cove, in charge of R. H. Benedict and B. O. Kempfer, is developed by 4,000 ft. of adits and cross-cuts. Its mill is equipped with jaw crushers, Huntington mills, and tables of the Wilfley, Overstrom, and Standard make. One or two sets of rolls will be added next spring.

The Buckeye is situated on Little Cracker creek, in the vicinity of Bourne, and is owned principally by Jas. B. Slpe, of Pittsburg, and T. S. Kennerly, of Sumpter, the latter being the manager. The development is in the nature of adits on the vein. The main vein is on a contact of quartzite and slate, the width being about 50 ft. between walls. Another vein, parallel to the principal vein, is within a porphyry dike that cuts through the slate. The ores comprise copper-iron sulphides, bearing gold and silver, much of the gold being free. Good buildings have been erected and development is in progress.

Recent heavy snows in the Blue Mtn. serve to improve the haulage, as sleds are now in general use, and on such roads as can be kept open the sleighing will be good for the next two or three months, and this will be the most favorable time for hauling ore and concentrate.

The Sovereign Consolidated Copper Co. was incorporated last month to develop a copper lode in the vicinity of Sparta, 35 miles northeast of Baker City. The directors of the new company comprise James A. Howard, John Arthur, K. O. McEwen, W. J. Patterson, and John Rand, all of Baker City. The first three named operated several years ago in the Sumpter district. The lode is silicious, and cuts through a greenstone country. On the surface is a cap of gossan, from which the copper has been partially leached out, a re-deposition of the copper appearing at greater depth. Pits and shafts on the property show copper ore running from 2 to 10% for the depth of 40 ft. Cross-cuts to the lode from a lower point furnish evidence that the sulphides begin at 100 ft. down. The lode varies in width from 100 to 220 ft. The property is to be developed vigorously this year, and those in control believe that by doing so they will soon be in position to supply an ore that will smelt profitably itself and mix advantageously with the silicious ores of the Sumpter district.

Within the last few days $10,000 in free gold was taken from the Emmett vein of the Virtue Mines Development Co., near Baker City. This amount of money was taken from less than a ton of quartz, which came from a depth of 25 feet.

Sumpter, Jan. 3.

SOUTH DAKOTA.

LAWRENCE COUNTY.

Anticipating the walk-out of the miners and millmen who voted to remain away from work if the eight-hour day was not granted, the seven companies affected by the demand have closed their properties. Both sides are determined in their stand, and no negotiations are under way. The properties concerned are: The Golden Reward, Mogul, Imperial, Reliance, Wasp No. 2, the Lundberg, Dorr & Wilson, the Portland, and Clinton. It requires about two days to clean up all the ore in the mills, before shutting down, and the operators met a committee from the union and asked to be allowed to retain a sufficient force of men for this purpose for two days longer, but the union refused to grant the request. Before closing down all the horses used underground were hoisted out, and 60 head have gone to the country for pasturage. The fires under the boilers have been drawn, and all pumping has ceased, as the demands of the union included pumpmen, topmen and engineers. At the Golden Reward, where the water has proved a costly item, the pumps were pulled out, and all shafts will be allowed to fill up.

BRITISH COLUMBIA.

(Special Correspondence).—The Inland Empire M. & M. Co. has been incorporated by Alfred Bachtold and associates, of Walla Walla, Washington, to develop and operate a property 10 miles from Nelson. Sufficient work has been done to show a good body of iron sulphide ore, which runs well in gold and silver. Plans are being made for a concentrating plant.

Spokane, Jan. 12.

The Consolidated M. & S. Co. has purchased the Enterprise claim. This company now owns 4,500 ft. along the Centre Star-Le Roi lode, which runs through the Enterprise, Idaho, and Centre Star claims. The Consolidated Co. received 2,115 tons last week at the Trail smelter.——The lessees of the Cariboo property at Camp McKinley are unwatering the mine. Three pumps are at work and the water is below the 200-ft. level.——The ore shipments for the week ending Jan. 5 were: Boundary, 3,562 tons; Rossland, 2,692; and Slocan-Kootenay, 1,486 tons. Smelter receipts: Granby, 1,908 tons; B. C. Copper, 6,900; Dominion Co., 2,558; Trail, 3,115; Nelson, 245, and Marysville, 600 tons.——The mines of Prince of Wales Island are shipping steadily to the Coast smelters. Mt. Andrews, owned by the Britannia Syndicate; Karta Bay, under lease to the Alaska Copper Co.; and the Jumbo mine of the Alaska Industrial Co., are all shipping ore.——The principal productive mines in the Kootenay camps are: The Silver Cup and the Sunshine mines from the Lardeau district (Trout Lake and Ferguson camps); the Paradise, Nettie M., and Athalmar mines in northeast Kootenay; and the Arlington and Ymir mines, near Slocan City.——The St. Eugene in East Kootenay is a large producer of silver-lead ores. This property is now owned by the Consolidated M. & S. Co. of Canada. At this mine 84,066 tons of ore were milled during the first half of last year, producing 14,000 tons of concentrate, which was shipped to the smelter, with 1,489 tons of crude ore.

Personal.

R. G. HANFORD has gone to New York.

LIONEL LINDSAY has gone to El Oro, Mexico.

F. L. BOSQUI is at the University Club, Denver.

W. M. BREWER has returned to Victoria, British Columbia.

EUGENE A. H. TAYS is visiting San Francisco from Mexico.

ARTHUR L. PEARSE is on his way from Salt Lake City to London.

JOHN A. REID has been on a visit to San Francisco from Stockton.

T. J. JONES, of the Mountain Copper Co., is on a vacation in the East.

C. W. PURINGTON is at Boston; he will proceed to London shortly.

E. A. WALL has returned to Salt Lake City from a short visit to Chicago.

ERNEST H. SIMONDS now has his office at Room 230, 787 Market St., San Francisco.

BEN S. REVETT is spending a few days at Breckenridge, before proceeding to New York.

N. W. HARPER has been appointed manager of the Golden Pole mine, in Western Australia.

W. J. LORING, who now resides at Melbourne, is visiting Western Australia, on a tour of inspection.

R. H. BURROWS has returned to Guanajuato from six months' professional work in Sinaloa, Mexico.

W. H. KNOWLES has returned to Denver from the investigation of mining property at Goldfield, Nevada.

G. E. KING, formerly superintendent of the St. Eugene mine and mill at Moyie, B. C., is now at Spokane.

J. L. PARKER, lately manager for the Brown-Alaska Co., has opened an office as consulting engineer at Seattle.

GODFREY DOVETON, of Denver, is at the Esperanza mine, El Oro, Mexico. He will return to Denver early in March.

WM. M. STEPHENSON has been appointed smelter superintendent for the Weimer Copper Co. of Idaho, with headquarters at Salt Lake City.

JESSE SCOBEY has resigned as manager for the Pride of the West Co., on the sale of the property to George Westinghouse. He is now inspecting mines in Jalisco, Mexico.

ROBERT PEELE has withdrawn from the firm of Olcott, Corning & Peele, on account of increasing work at Columbia University. The business of the firm will be continued under the name of OLCOTT & CORNING.

HOWARD P. SAUNDERS has opened an office at 319 Dooly Block, Salt Lake City, where he will conduct a general consulting and engineering business. He has been appointed consulting engineer for the Tintic Smelting Co., and for two other smelting companies.

NORMAN CARMICHAEL, superintendent of the Arizona Copper Co.'s mines at Morenci, has been appointed assistant general manager for the Company and second vice-president of the Arizona & New Mexico Railroad, with headquarters at Clifton, Arizona.

Obituary.

One of the best known and most loved men in the engineering field passed away Tuesday, January 1, in the sudden death at St. Mary's hospital in San Francisco, of VINCENT H. MARTYN, after a week's illness with pneumonia. Mr. Martyn was but 32 years of age, but had won a high place in the estimation of engineering men and others in allied interests. He was Western advertising representative of *The Engineering & Mining Journal* and brought to the duties of his position an aggressiveness and faithfullness that won him admiration, and a genial nature and a jovial disposition that gave him hosts of friends. To those with whom he thus came into contact the news of his demise will be a sorrowful shock. Interment was at Oakwoods, Chicago, on January 9.

Books Received.

ENGLISH WEIGHTS AND THEIR EQUIVALENT IN KILOGRAMMES is a little pocket-book of 90 pages, compiled for the use of merchants and shipping agents. It was prepared by F. W. A. Logan, and is for sale by the MINING AND SCIENTIFIC PRESS for 50 cents. Pounds avoirdupois, the British complicated subdivisions, and kilos are given side by side. To those who are operating in Mexico this little brochure ought to be of service.

GOLD MINING MACHINERY by W. H. Tinney. This is a practical handbook for the use of mine managers and engineers, it deals with the selection, arrangement, and installation of machinery. The book contains 300 octavo pages, well illustrated. It is written by a mining engineer, who formerly was in charge of mines in India and West Africa. It is a useful volume. Published by D. Van Nostrand Co. and for sale by the MINING AND SCIENTIFIC PRESS at $5.

THE ENGINEERS SKETCH-BOOK by Thos. W. Barber is published by Spon & Chamberlain. It is a book of 355 pages and gives 2,987 sketches illustrating details of mechanical movements, devices, appliances, and contrivances employed in the design and construction of machinery for every purpose. The aim is to provide side by side suggestive sketches of the various methods in use for accomplishing any particular mechanical movement or work, in a form easily referred to, and devoid of needless detail and elaboration. A sketch, properly executed, is—to a practical man—worth a folio of description; and it is to such that these pages are addressed. For sale by the MINING AND SCIENTIFIC PRESS for $4.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

BAROMETRIC readings rise or fall approximately one inch for each 900 ft. of depression or elevation.

Cobalt was formerly used almost solely to color glass, enamel, and porcelain, as it produces the purest of the fast blues. Lately it has been ascertained that it is valuable in the manufacture of storage batteries.

IN most cases fusion is attended by an increase in volume; to which there is the prominent exception of ice; also bismuth, antimony, brass, iron. Metals like these are best for casting, as they give sharp impressions. For this reason bismuth and antimony are used in type metal.

AT very high voltages there is an important leakage of energy between the conductors of a circuit, and this loss varies inversely with the distance between these conductors. Thus it happens that inductance makes it desirable to bring the parallel wires of a circuit close together, while the leakage of energy from wire to wire makes it desirable to carry them further apart.

MANY alloys soften gradually, the most fusible constituent melting first. Others have a fairly definite melting point, usually lower than that of their constituents. For example, Wood's fusible metal, four parts bismuth, two lead, one cadmium, one tin, melts at 60°C. Steel and cast iron, containing carbon, melt at a much lower temperature than cast iron. Alloys are considered to be solutions of solids in solids.

THE smelterman often receives his ores, which are valuable products, and stores them carelessly or at least inconveniently, for handling and charging to the furnace; while, at the same time, he takes great pains as to the disposal of the slag (a waste product) as cheaply and conveniently as possible. Why be so careful in the latter case with that which is worthless, while the valuable material runs the risk of loss?

A CONVENIENT FORMULA for the calculation of true meridian is the following:

$$\text{Cos A} = \frac{\text{Sin d}}{\text{Cos L} \,.\, \text{cos h}} - \text{tan L} \,.\, \text{tan h}.$$

where A = Azimuth of sun from south, L = latitude, h = altitude — refraction, and d = declination (+). This is far simpler than the cumbersome formulæ usually found in many of the standard surveying textbooks, and is now being used a good deal.

In regard to the enquiry concerning screens: A rotary screen (trommel) or 'impact' screen will separate coarse and fine sands. Try a cone separator (hydraulic classifier). This can be adjusted to produce almost any reasonable result that may be desired. The quotation concerning extraction is not clear. It may refer to the treatment of Homestake ore, where 50 to 60% is saved by amalgamation. The settling cones are employed to effect a partial (only) separation of sand and slime, which are treated later in separate plants.

AN effective method of agitating pulp containing 40 to 70% sulphides is by means of a horizontally disposed 'propeller' or screen. This is secured to a vertical shaft running in bearings and driven at the upper end by belt or gears. The pulp must not be allowed to become so deep as to submerge the 'propeller,' or it may cake and hold the latter so firmly as to make excavation with shovel necessary. In the event of stoppage, for either a short or long time, the pulp settles, but it may quickly be stirred up by revolving the screen; this creates such a strong downward current, that the material is quickly taken up and held in suspension in the rapidly whirling solution of cyanide or whatever the liquid may be.

WHEN ore contains a large percentage of sulphides, and the gold is saved by amalgamation, it is necessary that the outside plates be given a heavier grade than when treating free-milling ore. It is useless to quote an arbitrary grade, but 2.5 in. per ft. would probably be about right. The plates should be so arranged as to change the grade to suit varying conditions. A larger amount of water will be required than with ore containing a relatively small percentage of sulphides. The fineness of crushing, character of sulphides, and their kind also, are important factors, due to difference of specific gravity and the cleavage of the several kinds of sulphides. A shaking plate will usually give better results than a stationary one, on heavy sulphide ore.

IT IS quite possible to splice rubber belts successfully. The mode of procedure is to strip each ply of each end of the belt about 18 in., then one ply of one end is laid on the corresponding ply of the other end and cement is applied, which is allowed to soak into the belt for three or four hours. The same treatment is given the next plies and then the belt is vulcanized in the press. If the belt is to be the same length as formerly, a new piece of belt must be spliced in. Rivets are not necessary. To secure a good piece of work, the belt should be sent to some manufacturer of rubber belting, of which there are two or three in San Francisco. If the belt is an old one it would be better to lace it, unless it is being used on a dynamo or other machine running at a very high speed.

THE USE OF OIL IN THE BLAST-FURNACE.—T. Holloway has used oil in a small experimental furnace and also in a 10-ton furnace where refractory zinc-lead ores are treated, for a period of upward of five years. The oil was used to assist the smelting in a temporary way, and to remove crusts or accretions by smelting them out. His arrangement consists in fitting a small pipe with a regulating valve from an overhead oil-tank to the entrance of each tuyere opening, so that the oil, as it drops across the tuyere, is caught and atomized by the blast (10 oz. or more), volatilized by the heat of the furnace, and burnt as gas. The oil was only used as necessary in regulated flow to heat up the furnace at the tuyere region and to smelt out crusts which might have formed. It gave extra heat at a moment's notice to the smelting zone and the cost and amount used was small.

THE pollution of air in mines is sometimes due partly to the emanation of gases from the surrounding rocks, but principally from the following artificial causes: (1) Respiration of persons and animals, (2) combustion of the candles and lamps, (3) absorption of the oxygen by pyrites and other minerals, (4) putrefaction of timber, (5) explosion of powder, (6) dust from boring, etc. Of these the decay of timber underground is one of the most important, and it should be urged that the practice of leaving the useless decaying timber to infect the new pieces put in, sometimes making a level a hotbed of putrescent matter, is both offensive to the senses, and injurious to the men. One of the recommendations of the Ventilation of Mines Board in Victoria (Australia) was that all the bark should be removed from the timber before it was sent underground.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Black Sand.

The Editor:

Sir—I have noted with much interest Mr. Maxwell's letter in your issue of November 10, referring to this subject, and having personal as well as business interests at stake, I am equally as anxious as Mr. Maxwell to obtain ideas and solve the problem.

Unfortunately for the interest of abstract science, many other workers, like myself, are no doubt engineers employed by large firms, who cannot, in justice to themselves or their employees, reveal all the knowledge that they acquire. There are, however, a number of points of general interest open to discussion by all parties, and I take pleasure in calling Mr. Maxwell's attention to some of them, and trust that this may also be the means of raising a general discussion in the columns of your journal.

There is no new discovery about 'black sands.' They are to be found disseminated throughout the sand and gravel—both ancient and modern—of practically all river, lake, and sea-beach deposits. The sand consists of numerous particles of different minerals having a high specific gravity, and of such a nature that they cannot be readily decomposed by the action of weather or water. The various minerals are merely associated together by virtue of the fact that they are all of high specific gravity, and also, that owing to their durable structure, Nature has had the opportunity of concentrating them in the river channels from a vast area of country from which they were originally eroded, and the nature of the minerals composing the grains will therefore largely depend upon the geological features of this area. The grains are of all sizes, from a maximum of about ¼ in. diam. down to material that will pass through a 200-mesh screen or even finer.

The whole question is simply one of ordinary placer mining, with some definite system worked out for saving a larger percentage of fine gold and also of saving all of the other by-products that have hitherto been allowed to run to waste, and of doing this on a strictly commercial basis, without undue capital expenditure and at such low cost of operation that a sufficient profit will result to repay capital, interest, and a good surplus besides, before the deposit is exhausted.

Wild statements have been made regarding the value of black sands, and samples have been submitted which assayed $1,000 per ton, but it must be remembered that these samples consisted of a few pounds *actual weight* containing a few dollars *actual value*, that had been concentrated down from possibly many hundred cubic yards of gravel, and that before one ton could be obtained, probably 4,000 to 5,000 tons of gravel had to be washed down, so that the real value of the original deposit in place possibly did not exceed 20 cents per ton. The first thing to be done, therefore, is to base all reports on the value per original ton or cubic yard of gravel in place, from which the black sand concentrate has been obtained.

When dealing with the mining of an alluvial deposit for the extraction of black sand and its and associated minerals as a commercial proposition, I would suggest the following line of procedure:

First, a survey should be made to show the topography of the surrounding country, and of the surface area; the length, breadth, and depth of the deposit, especially with relation to the drainage. Data should be collected regarding the maximum, minimum, and average flow of all streams and rivers in the neighborhood. In river deposits, the possible flood line is of great importance. Possible hydro-electric power sites in the neighborhood should also be noted, as there are many modern methods applicable, that were not within reach of the early placer miners, where electric power can be obtained conveniently for pumping, elevating, and conveying, and for driving the necessary machinery for any plant that may be installed.

Second, the ground should be thoroughly tested either by drilling or by shafts; if the seepage is not excessive, the latter is preferable. In case of an elevator proposition, the proportion of fine to coarse gravel must be carefully noted as follows:

The proportion by volume per cubic yard of all gravel below two inches, from 2 to 5 in. and from 5 to 12 in. Gravel over 12 in. must be considered as too large either for practical dredging or for hydraulic elevating.

If conditions permit, the whole of the gravel extracted from the shafts should be washed, and the coarse gravel stacked on one side. This may be conveniently done by means of a washing platform discharging by a short sluice into two or more pairs of rockers, which may alternately be cleaned up at short intervals. No riffles should be put in the sluice, nor quicksilver used. The clean-up of the rocker riffles must be passed through a 10-mesh screen, the undersize going directly to a settling vat for further test treatment and the oversize being roughly picked over and thrown to waste. Any coarse nuggets or gold that may be caught on the rocker grizzlies or on the washing platform, should be kept separate and their individual weights and measurements recorded.

That which is saved in the riffles of the rocker may be considered as material that could be saved by ordinary sluice-box methods and that could certainly be saved by sizing and concentrating on the tables. The tailing from the rockers must also be weighed and passed through a 10-mesh screen. The oversize should be roughly picked over and then thrown to waste, and the undersize 'panned down' by panning back and forth between two miner's pans. If skill and care are exercised, practically all of the black sand that has escaped the rockers can be saved by this method. All of the concentrate caught by this means, will have to be tested as mentioned below.

The gravels of different mines vary so greatly, as do also the proportion of the different associated minerals and the size of the grains, that it is more than probable that each particular plant will have to be designed with regard to the local conditions. I think, however, it will be generally conceded, that all gold and platinum grains above ¼ in. diam. are comparatively easy to save. The real question is how to save the fine, and especially how to separate as well as save the associated by-products, without destroying one to save the other. The following additional tests are therefore necessary, and will aid in throwing some light on a possible solution of this problem.

The material saved from the settling vat of the rockers, and from the pan concentrate, should be carefully dried in sheet-iron trays over a roughly constructed furnace. For small tests, the miner's gold pan may be used for this purpose. Care should be taken to make certain that the settling vats are thoroughly clean and also that the trays are carefully dusted after the product has been dried, as otherwise some of the fine gold is liable to be lost. The dried product should now be weighed in bulk and a record made of its actual weight in pounds and of its proportionate weight per cubic yard of gravel from which the concentrate was extracted. For small hand tests, it is most convenient to give the weight in grams and for the large tests in pounds, though if the facilities exist, it is far best to use the metric system right through. Unfortunately most miners do not understand the metric sys-

tem, and a report to be intelligible to them, must be given in cents per cubic yard, and the weights in pounds.

The dry product should now be passed through a series of ordinary laboratory sieves from 10 down to 100 mesh or even finer. Each oversize will be carefully separated and weighed in bulk, the magnetizable product will be removed and weighed and the residue can then be conveniently treated by the old-time method of blowing, care being taken to blow the tailing on a large sheet of paper, so that it can be collected for further treatment. The gold particles remaining in the small blower must then be weighed on a button balance and placed in a small vial properly labeled for future reference. An assay sample should be taken from the original pan concentrate and also from the magnetizable product and the residue after the gold grains have been removed, and assays made and recorded. This process may be carried on for the oversize of all the different screens and the final undersize, which passes the finest screen used. The results of these tests may then be tabulated.

As the result of these tests, it will now be possible to form some idea as to where the values exist, that is, so far as the gold is concerned, but it will be found to be exceedingly difficult to remove the gold from the platinum, except by resorting to the usual refinery methods. The residue remaining after removing the magnetizable product, will consist of other by-products, some of which may have a commercial value, together with a certain amount of fine gold, and just here is where the great field for research is open; for at the present moment, I do not know any process by which these different products may be separated and put into marketable form.

Care must also be exercised in making a magnetic separation of the magnetizable particles, for if too strong a magnet is used and swept hurriedly through a large mass of sand, the clusters of iron grains will almost always pick up and hold in suspension a certain number of gold particles. For laboratory purposes, I have found it most convenient to use an ordinary 5 or 6-in. horseshoe magnet and to cover the poles with a fine cambric bag. I then spread out the sand to the thickness of 1/16 in. on a piece of paper; and gently pass the covered magnet back and forth over the surface, and the magnetizable grains will cluster on the outside of the bag. The covered magnet with its adhering particles is then placed in a glass bowl and the magnet withdrawn from the bag and the latter shaken. This operation should be repeated until all the magnetizable product has been separated from the sample. The product collected should again be spread out on a piece of cardboard and gone over a second time with the magnet; this time, however, the bag must be drawn tightly over the poles of the magnet, and the latter must be tapped gently while picking up the grains, so that any non-magnetizable gold or platinum particle will be freed from the clusters and fall back on the cardboard by virtue of its specific gravity. The use of a bag as described above will be found to facilitate the operation, and is much quicker than placing the bare poles of the magnet against the black sand.

The gold that has been separated should be carefully examined under a glass, and notes made regarding its surface appearance. It will also be a good plan to make an amalgamation test and find out by weighing what proportion of the gold will or will not readily amalgamate.

As a result of these tests, we now have the following data:

1.—The weight of fine products resulting per cubic yard of gravel that will have to be treated by concentration, and we can now therefore estimate upon the necessary talbe area per cubic yard of gravel to be washed.

2.—The weight of black sand concentrated per cu. yd. and the approximate gross value per ton of concentrate, and also per cubic yard of gravel.

3.—The proportion by weight of separation that can be made by magnetic methods.

4.—The values, if any, that are in direct association with the iron grains and would be lost by this method. Gold and platinum assays should be made.

5.—The values that remain in the non-magnetic residue subsequent to wind separation of the clean gold, and that with our present knowledge can only be saved by smelting.

6.—The value of the clean gold that has been caught by the three processes.

7.—The proportion of gold that will amalgamate, and if the non-amalgamating gold is coarse or fine.

7.—The quantity of residue containing the by-products that need further treatment.

In the foregoing, I have merely outlined some of the most important tests, though numerous others will no doubt be made before a final solution of the problem can be arrived at. We may, however, now commence to formulate some definite arrangement for a plant to treat the black sand and to indicate the nature of the problems most likely to be encountered. Broadly speaking, all of the coarse material of a placer is valueless and therefore the sooner it is dumped and gotten rid of, the better. All coarse gold above ¼-in. size is easy to catch, and an arrangement of a few riffles in a short line of sluices will take care of that feature. Hence the first and most important step is to size the material say to ¼ in. and reject the coarse after passing through a sluice. It will be equally necessary to get rid of the excessive quantity of clay and fine product, which might impede the successful operation of further concentration.

As dump is an important consideration in many placer mines, it will be necessary to design a plant with as little loss of head room as possible, and I would suggest the following arrangement: At the discharge end of a sluice, where the material is received from mining operations, a grizzly should be placed, having a sufficient area to pass all of the fine material and practically all of the water. It should be placed at such an angle that the coarse material will roll off to dump. The grizzly should be provided with taper bars and spaced about 7/16 in. All of the fine material will pass by a large sluice to a distributing and hydraulic classifier, which will get rid of the excess water and very light sand and clay held in suspension.

As a certain amount of float gold might be carried away to the reject, I would suggest that this be passed through some form of amalgamating device, the Pierce amalgamator being a good machine for this purpose, and as the light gold has probably a clean surface, it will be fairly easy to amalgamate. It will, however, be advisable to make a number of tests by means of settling vats, to find out whether the value of the gold and by-products saved will be worth the capital outlay necessary to save them.

The heavy sand from the hydraulic classifiers will pass to some form of classifying sieves, designed to handle a large bulk at a minimum of capital and current expenditure. These should size from 5/16 to say ¼ in., and must be of simple and durable structure, or the placer miner will never bother with them.

To size all of the material from a placer mine, to reduce the product to be treated to a minimum bulk, economically and without loss, and to deliver it in a form suitable for further concentration and treatment, is a matter that offers a broad field for intelligent design and invention. The quantity and proportion of this sized

product to the original gravel will vary according to the nature of the gravel being mined, and judging from my own experience, it will be least in modern river channels and greatest in deep, ancient deposits, and may vary from 20 to 60% of the original gravel in place.

Some form of concentration must now be adopted to treat the fine material, and although cocoa matting tables with expanded metal riffles have been used fairly successfully for the purpose, they are to be condemned because they are not continuous in operation, and all forms of non-continuous concentration are bad, owing to the fact that the surfaces choke and the values commence to slide over and are lost. This can be mitigated to a certain extent by frequent clean-ups, but this entails too great an outlay for current expenses, and quickly reduces profits when treating such a low-grade product as the sand of a placer mine.

The Pinder concentrator has been proved by actual tests to be one of the best machines on the market for this purpose. Its capacity is about 40 tons per day, equivalent to handling the product from 60 to 100 cu. yd. of gravel. Furthermore, it is capable of delivering three grades of concentrate and tailing. Any form of concentrator, however, could be adopted, according to the ideas of the mine owner, and the results of actual tests will soon prove which is the best machine.

Whatever form of machine concentration is used, whether all the material is passed to the tables or whether another hydraulic classifier is used and the fine is passed to belt machines and the coarse to tables, the resulting concentrate will require still further treatment if a clean separation of the gold, platinum, and other by-products is to be made. My own experiments would indicate the following procedure to be possible: First, dry all the concentrate at a high temperature; in some cases it might be necessary to roast; this is a matter for experiment and research, and the most suitable form of dryer a matter for invention. The amount of resultant concentrate to be handled by this method will be from ¾ to 2 tons per 500 cu. yd. of gravel in place, so that a mine handling 10,000 yd. per day would require a dryer, etc., of a capacity not exceeding 40 tons per day.

The dried product may first be treated by magnetic separation to remove the magnetizable iron grains. Here is another big field for research, observation, and invention, as nearly all of the magnetic separators on the market at present, from various causes, one of which I have already indicated, rob too much gold and platinum. After the magnetizable product has been removed, the product remaining, which is now much reduced in bulk, will require further treatment. At this stage it will probably pay the practical placer miner to ship his product to the smelter, as any further process will doubtless require the services of a skilled metallurgist.

The following suggestion, however, may be of service: Treat with diluted nitric acid; wash, amalgamate (without grinding) to remove the free gold; wash the residue through a fine steel-wire sieve. If platinum is present, this can be dissolved by acids, using about 15 times its weight of aqua regia and precipitate by sal ammoniac. The precipitate of platin-ammonium chloride can be dried and treated by the usual refining methods. Any base metals will probably already have been removed by the nitric acid and amalgamation treatment.

JOHN M. NICOL.

San Francisco, January 5.

THERE are some people who always know which is the north; and others who, if asked suddenly, do not know their left hand from their right; and others, again, who say—or shout—that all men are created equal.

Standardization of Weights and Measures.

The Special Committee appointed by the council of the Institution of Mining and Metallurgy, London, submit the following recommendations:

1. That the word 'ton' shall represent a weight of 2,000 lb. avoirdupois, that the terms 'cwt.' (hundredweight) and 'qr.' (quarter) be abolished and that fractions of a ton be expressed either in pounds or in decimals of a ton.

2. That the 'miner's inch' be understood to mean a flow of 1.5 cu. ft. water per minute.

3. That the word 'gallon' be understood to mean the Imperial gallon of 10 pounds.

4. That all the temperatures be expressed in degrees Centigrade.

5. That gold and silver ore-values be expressed in terms of fine gold and silver and not as 'bullion.'

6. That gold contents be expressed in sterling values as well as in weights.

They also suggest that the following questions be appended to any memorandum that may be issued to the members of the Institution embodying the above definitions:

a. Do you consider the general adoption of the Metric system of weights and measures to be feasible, or would this in your opinion lead to undue dislocation?

b. Have you any suggestion to make as to weights and measures other than those already dealt with which require exact definition?

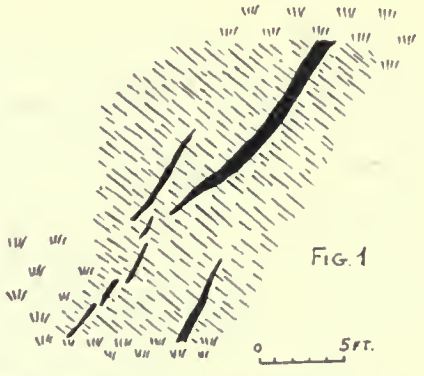
The question of the adoption of Metric standards has engaged the attention of the Committee, as the present movement in that direction in other banches of industry rendered it in their opinion inadvisable to ignore it entirely. The feeling of the Committee, however, is that, while the question should be brought to the attention of the members, it would at present be quite inexpedient to advocate the general adoption of the Metric system. On the other hand an attempt to decimalize existing weights and measures is considered to be a step in the right direction, and as tending to bring about a simplification that would go far to obviate any desire to adopt Metric standards, and this has been kept in view in the foregoing recommendations.

HELMHOLTZ was fond of saying, in proof of the imperfections of the human eye, that he would unhesitatingly reject any piece of work sent to him by an instrument-maker which should prove to be equally full of defects. It is needless to accumulate illustrations of a fact which is familiar to all scientific workers, and which the wisdom of the ages has vainly tried to combat in the aphorism that "seeing is believing." To give only one instance of the untrustworthiness of the human eye, it is still debated whether the so-called canals which the telescope seems to reveal on the surface of Mars are not an optical delusion, due to the inveterate tendency of the eye to arrange separate and unconnected markings into a linear pattern. Any one who has watched a really good conjurer is well aware that seeing is not always believing; we see him quite distinctly take a coin out of his left eye and convert a playing-card into a white-rabbit; but all the same we do not believe that he does it. Yet it is almost entirely through the medium of this imperfect and deceptive instrument that we are obliged to prosecute those researches into the nature of things which, under the generic name of science, have done so much to change the conditions of life, and the outlook of mankind upon both the material and the spiritual universe. Fortunately, we are able to check the messages which the eye sends to the brain by the indications of other senses, as well as to supplement its native weakness by instrumental aids.

Dikes.

Written for the MINING AND SCIENTIFIC PRESS
By JAMES F. KEMP.

The accumulated observations of many geologists have taught us that eruptive rocks occur in the following forms: Dikes, necks, stocks, surface flows, intruded sheets, laccoliths, bysmaliths, conoliths, and batholiths. Some of these names are merely introduced here to excite the curiosity, or (it may be) the alarm, of readers of the PRESS, but the others evince their face-value on sight. Of them all, the one most often concerned with mining is the dike and it is the one which, in many respects,



Very small dikes, near Schroon lake, New York. The country rock is gneiss. Report N. Y. State Geologist, 1895, p. 600.

presents the most interesting features. The larger forms chiefly manifest themselves as so much wall-rock which extends far and wide. For example, the close association of a porphyry dike with a vein in the desert region of southern Nevada and California is its surest claim to the respect and considerate attention of the prospector.

A dike is a relatively long and narrow body of igneous

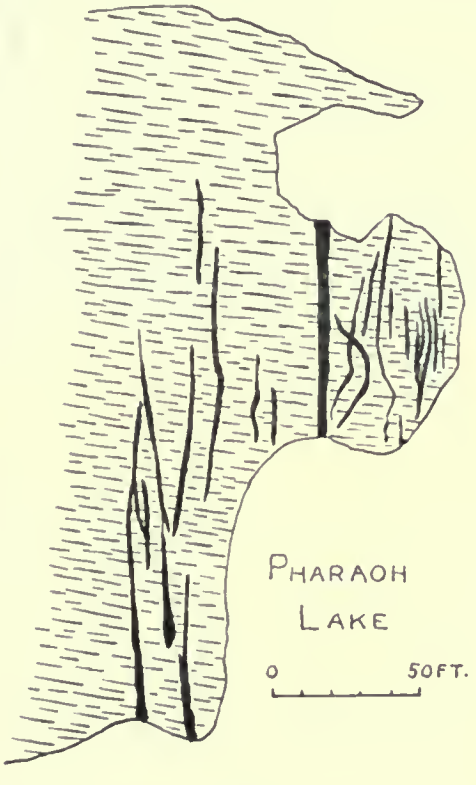


Fig. 2.

Small dikes on the shore of Pharoah lake, southern Adirondacks. Report N. Y. State Geologist, 1895, p. 599.

rock, which has been forced, while yet molten, into a fissure in older rocks. In typical cases dikes are approximately vertical, and in sedimentary rocks they cut across the stratification. It is necessary to mention these features, in order to distinguish them from intruded sheets, which are parallel with the bedding and which are, in typical cases, approximately horizontal. If, however, a steeply-dipping or vertical sedimentary series is penetrated parallel with the stratification by long and narrow bodies of eruptive rock, the distinction becomes less pronounced. Sheets, however, do not cross the bedding, unless for short distances they jump from plane to plane, only to resume their original course. But it is evident, on reflection, that intruded sheets in steeply-dipping sediments present transition forms to dikes.

Dikes, as exposed, vary from the fraction of an inch in width and a few feet in length, to hundreds of yards in width and miles in length, the main point being that

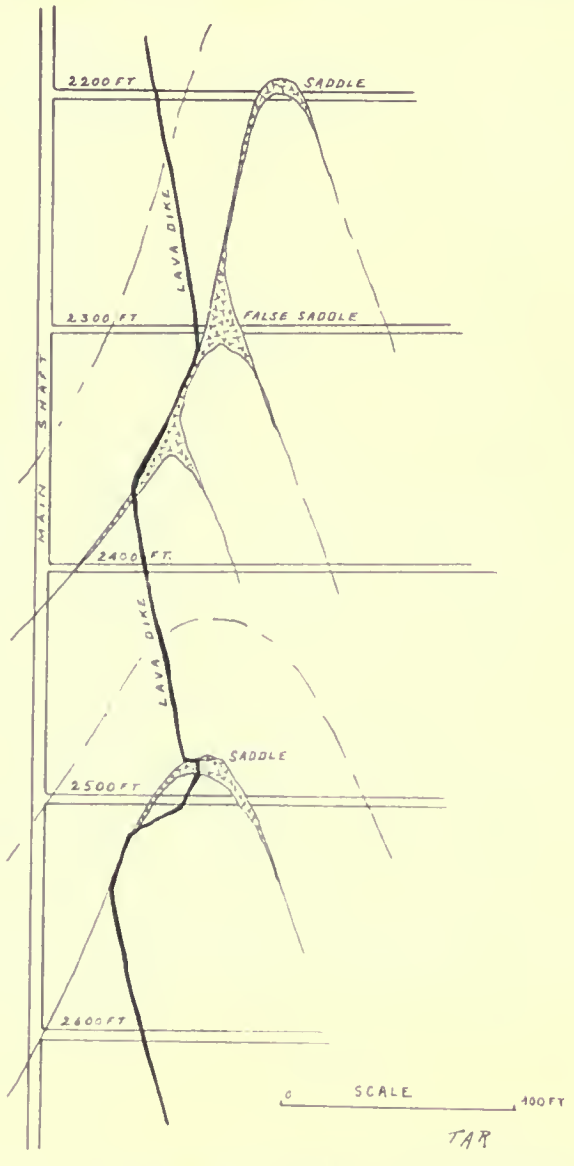

Fig. 3. Nine-inch Dike in the 180 Mine at Bendigo, Australia.

the width is small as compared with the length. When the length becomes relatively small and the width relatively large, dikes pass into stocks and necks, which thus constitute limiting forms. The small size is one of the most remarkable features. In the eruptive and metamorphic areas of the Adirondacks, little basaltic stringers are sometimes seen, scarcely half an inch wide, and no more than a foot or two in length, yet always in groups and making the observer conclude that the molten rock has searched out every nook and crevice in the walls, as would so much water under pressure.

The extraordinary persistence of these narrow bodies without great change in width is very striking. Many examples may be seen along the coast of Maine, New Hampshire and Massachusetts, where, for several hun-

dred yards, a dike will be less than a foot in cross-section. The same persistence holds good in depth. In the 180 mine, at Bendigo, in Victoria, Australia, where the saddle-reef is the characteristic goldbearing formation of the region, a basaltic dike has been followed to a depth of 2,600 ft., without varying much from its width of nine inches, as first discovered at the surface[1].

At the other extreme, however, very large dikes have been recorded. The late Carvill Lewis[2] traced one of diabase in southeastern Pennsylvania, for 90 miles. In following dikes over such an extended area the observer cannot always secure actual outcrops, but must connect scattered exposures, which are ranged, however, along the same line. He must assume the presence of the eruptive beneath the soil, the forest, and the loose surface deposits. He should always endeavor to check the inference by lines of boulders in unglaciated regions. In glaciated regions, of course, boulders have no local significance.

Dikes rarely occur singly; it is the rule to find them in parallel series, but large individuals almost always send branches into the wall-rock. This relation may be of great practical importance, as is illustrated in the Gogebic iron range of Michigan. The iron ore deposits are due to the troughs, which are made by northerly dipping dikes with southerly dipping quartzites, on which rest cherty iron carbonates. Both quartzites and dikes being impervious rocks, the iron ore which has been leached out of the cherty carbonates has come to rest in the troughs and has been precipitated. The parallel and branching dikes have brought about repetitions of the troughs and have thus multiplied the number of ore-bodies. Ore having been penetrated or exhausted in one trough, another may be found by following down on the quartzite.

When platted on a map, the parallelism of scattered and poorly exposed individuals over wide areas may sometimes be brought out in a marked manner, as has been proved to be the case in the Adirondacks. They may then be shown to follow systems of joints or faults, and—conversely—emphasis is to be placed on the importance and deep-seated nature of the joints or faults themselves. In the Adirondack case, basaltic dikes, which were noted in exposures miles apart, and among which no relationship was at the time suspected, were found to follow one marked series of structural breaks.

Dikes are at times wonderfully numerous, and afford one of the most striking of geological phenomena. The coast of Massachusetts, New Hampshire, and Maine, is thickly seamed with them. A. C. Lane[3] has recorded upward of 500, nearly all diabase, at the shore resort of Nahant, a few miles north of Boston. The entire area is little more than a square mile, and the dikes constitute from 3 to 6% of the total surface. N. S. Shaler and R. S. Tarr,[4] have mentioned the great numbers at Cape Ann, and have speculated on the compression which their intrusion must have produced in the country rock.

Dikes sometimes radiate from an eruptive centre. For them, when in this position, L. V. Pirsson[5] has suggested the name 'radial' dikes. The Little Belt (Montana) folio of the United States Geological Survey, shows some remarkable cases. The radial dikes in this case are basic or low in silica, while the eruptives of the central mass are relatively rich; hence the dikes are also spoken of, as complementary to the other eruptives; the two together making a mass of average composition.

In a few observed cases two dikes have successively entered the same fissure so that a composite dike has been afforded.[6] And again instances are known in which the same dike has split up into numerous thin masses as it penetrated the shattered rock. A. C. Lawson has described a case at the mouth of White Gravel river, on the northwest coast of Lake Superior, in which over fifty thin sheets of granite and diabase alternate, no one of them over 6½ in. across. The diabase is the younger and the dike has been called a 'multiple' dike by Lawson.[7] Zirkel[8] has mentioned a dike of such varying composition across its face as to be called a 'mixed' dike.

The mass of a dike is sometimes found to be richly charged with fragments of the wall-rock through which it has come. When these are collected and compared, they indicate the underlying formations. Thus a dike of trachyte at Nash's Point, on Lake Champlain, near Burlington, Vermont, contains (as inclusions) fragments of Trenton limestone, Cambrian sandstone and Archæan anorthosite, the wall-rock being Utica slate. From the known geological section it is inferred that the anorthosite came from not less than 1,000 ft. in depth.[9] The presence of abundant inclusions of this character indicates that the portion under observation is the advanced guard of the eruptive, as it was forced into the fissure. When the fissure was first produced there would naturally be much splintering of the wall-rock, but as the advancing portion of the dike passed on, it would carry with it the loose materials and finally embrace them in this upper portion when it came to rest. Dikes which have been eroded to any notable extent apparently do not contain these inclusions.

The enormous pressure under which these narrow bodies of eruptive rock must have been forced into fissures in order to split apart the wall-rocks has attracted the attention of some observers. N. S. Shaler[10] has suggested that when a dike penetrates rock which is well provided with water, the heat of the dike probably vaporizes the water as fast as encountered, and thus produces explosive steam which opens up the way. Whether this appeals to us or not, there is no escape from the conclusion that the hydrostatic pressure back of these entering wedges of molten material is enormous.

When the molten rock comes to rest in a fissure, especially in its upper portions, it speedily congeals and crystallizes. Almost always the portions along the contact and the narrow off-shoots show evidence of having quickly chilled. They are glassy or extremely dense. As, however, the central portions of even narrow bodies are approached, the crystals become larger and porphyritic or even certain varieties of granitoid texture may be attained. In large dikes in which the structure is granitoid, we find the minerals, almost all possessing their own crystal boundaries, and affording a texture fairly characteristic of this form of eruptive. Since the coarseness increases regularly from the edge to the centre, the size of the component mineral bears a definite relation to the original temperature, the conductivity of heat, and the temperature of the walls. Both A. C. Lane and later A. J. Queneau[11] have developed formulas whence, from measurements of the size of the minerals, the distances from the edge may be calculated and likewise the temperature of the molten dike at the time of entrance. Mr. Queneau endeavored to develop a method whereby, when a miner was penetrating a dike or sheet of barren rock, measurements of the size of the crystals, of necessity with the microscope, would give an idea of the distance yet to be traversed to reach the farther wall.

Dikes have frequently been shown to be more basic or

lower in silica at the edges, and more acidic or higher in silica at the centre. During crystallization the metallic bases seem, by some obscure process, to move toward the coldest portion, either by molecular transfer or flow, or else by convection currents. The change is somewhat analogous to the varying values in a solidified pig of base bullion from top to bottom, or from outside to inside, and to variations well recognized in chilled pots of copper-nickel-iron mattes. In a dike, the contrasts may be several per cent in silica. The changes have a bearing on the supposed igneous production of certain ores, and may at least make some parts, the outside for instance, more favorable for replacement processes than the inside. Sometimes when a large mass of eruptive rock has been partially congealed, it appears to have been cracked by the contractions from cooling, so that material, still molten below, has exuded into the fissures and has afforded dikes called 'extravasated' by W. O. Crosby. Dikes themselves may break up, from contractional strains on cooling, into basaltic columns whose long axes are perpendicular to the walls. The columns may be left in relief by the erosion of the wall-rock, so as to appear like masonry, or even like cord-wood, or again the dike may be removed leaving a narrow gorge, with an apparent stairway at the back. The coast of northern New England, above referred to, has many cases of the latter type. Dikes left in relief rather favor the more arid regions, and remarkable cases occur around the Ortiz mountains of New Mexico, and on the Spanish Peaks of Colorado.

The relative age of dikes is occasionally indicated by their intersections, the younger cutting the older. An exceptionally well exposed and interesting case is afforded by Lighthouse Point, near Marquette on Lake Superior. The country rock is a schist, produced by the metamorphism of a volcanic tuff. It has been cut by five successive intrusions of dikes. The oldest dike is cut by the other four, and so on down to the latest, which itself cuts all the rest. See Fig. 5.

Although dikes are themselves relatively small masses of eruptive rock, they indicate large reservoirs in depth, because it is inconceivable that they can have been produced in any other way, than as smaller offshoots of much larger bodies. They are found in regions remote from large masses of igneous rock, so far as surface exposures go, and amid geological surroundings where they would be least anticipated. For instance, at Syracuse, N. Y., and south of it, in the almost undisturbed Paleozoic strata, a goodly number has been discovered. Again in southwestern Pennsylvania, cutting as high as the Pittsburg coal seam, one is known, and in eastern Kentucky, several others, likewise in the coal measures. Isolated dikes, like these, are almost always very basic rocks, and usually peridotites. They make us wonder if it is safe to infer the underground absence of igneous phenomena in any quarter.

Fig. . Upstanding Dikes on the Flanks of Spanish Peaks, Colorado.

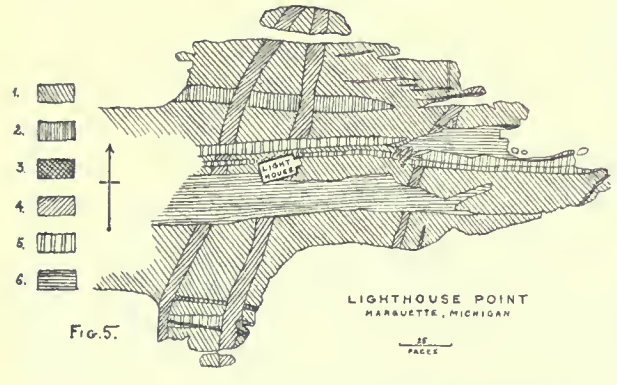
By Courtesy of U. S. Geological Survey.

Dikes sometimes exercise an important influence upon the local fertility of soils. In the wash of the well-known nephelite-syenite dike, a rock rich in potash, near Beemerville, N. J., the land is very productive. From Norway, however, we draw the most striking instance. As described by Dr. Kolderup, of Bergen, there is, near the village of Soggendahl, a great dike of dialase, extending several miles across a country whose rock is anorthosite, or almost exclusively labradorite feldspar. Where the

dike has contributed to the soil it is extremely fertile, and both crops and stock flourish. Back in the hills, on the contrary, the soil is far less fertile and the land is solely used for grazing. The anorthosite lacks phosphorus because of its small amount of apatite, and the cattle show the effects by weak bones and teeth. The farms and villages all follow the course of the diabase.

Dikes have also proved exceedingly serviceable sources of paving materials and in regions of soft country rocks they are quarried extensively for macadam. Basaltic dikes generally yield a road-metal with a good bond. Under metamorphism basic dikes yield belts of hornblende-schist which follow the old course of the intrusive with great fidelity.

In mining districts, dikes occasion particular interest. They have sometimes caused unnecessary alarm on the part of miners. Thus many years ago a basaltic dike, about 20 ft. thick, was encountered in mining the zinc ore at Franklin Furnace, N. J. It happened to cut the orebody, just where the latter pitched down beneath a cap of limestone, so that it was not apparent that the ore continued beyond the dike, and for awhile it was supposed that the eruptive had cut it off. The dike was hard and tough, resistant to the hand-drilling of the day,



Intersecting dikes at Lighthouse Point, near Marquette, Mich. The order of age is: 1, hornblende schist; 2, crushed felsite; 3, microgranite; 4, uralite diabase, altered; 5, uralite diabase; 6, quartz diabase. Geological Survey of Michigan, Vol. VI., p. 230.

but, when finally penetrated, the best ore of the mine up to that time, lay just beyond it. A similar experience for awhile caused some alarm 25 years ago in the Forest of Dean magnetite mine, southwest of West Point, N. Y. A basaltic dike cut the ore off, but in the end it proved but a few feet thick. In the magnetite mines of the Adirondacks, narrow trap dikes are met in almost all the slopes and very often occupy small faults along which the ore is thrown a few feet.

The presence of dikes in association with ore deposits, other than iron, is suggestive of the influence of eruptive processes upon the formation of ore. If it is appreciated that even a small dike is proof of the existence of a large parent body of igneous rock, in depth, and of a line of weakness leading down to it; and if the dike has entered just before the formation of the ore, the inference is inevitable that expiring igneous phenomena are connected with the deposition. Many such cases could be cited from Western mining regions. Thus at Douglas Island, Alaska, G. F. Becker noted a narrow basaltic dike in association with the ore. The introduction of the auriferous pyrite was supposed by him to have occurred simultaneously with the entrance of the dike or soon after. At Cripple Creek, Colo., the telluride ores are closely associated with phonolite and rare basaltic dikes, all appearing to be the closing products of the local volcano. In fact it is very exceptional in the West to find a camp where dikes or some related form of eruptive rock are not in close association with the ores.

Pegmatites constitute a connecting link between ordinary intrusive dikes and veins. They seem to have been formed by aqueo-igneous processes, so that one is often puzzled whether to call them dikes or veins. They shade off into quartz veins by imperceptible gradations and have much in common with the latter.

A very peculiar form of rock which is not igneous, but which has been described under the name dike, is the so-called 'sandstone dike,' first brought to general attention by J. S. Diller from observations in California. Long and relatively narrow masses of sandstone have in a few instances been discovered in fissures, which cut sharply across the stratification of sedimentary rocks. It is believed that they have been introduced as mud, in connection with earthquakes, and having been once poured into a fissure as an emulsion, they have then consolidated into firm rock. Although unfortunately called 'dikes,' they are nevertheless in no sense igneous. In the use of the words dike and vein, we should be equally careful to restrict the former to igneous intrusions, the latter to deposits from solution.

AMERICAN COPPER.—As recently as 1888, says '*The Copper Handbook*,' by Horace J. Stevens, the value of copper produced by the mines of the United States was only $33,833,954, and for 1904, only two years ago, was but $105,629,845, the year 1904 being the second in the history of the country in which the value of the copper output exceeded one hundred million dollars, yet, at the present moment, the copper mines of the United States are producing copper to the value of two hundred millions of dollars yearly, and the Lake Superior copper mines alone are making copper worth $150,000 for every day in the year, or at the rate of more than one million dollars weekly. So great has been the growth of the industry, and so rapid the increase in price of the metal, that the production of three counties of the single State of Michigan is as great in value as the entire copper production of the United States as recently as 1897—only nine years ago—and double the value of the entire copper output of the United States in a year as comparatively recent as 1889.

Figuring copper at an average price, throughout the globe, of 20½ cents per pound, which is a trifle below the average quotations, the mines of the world are making copper at the rate of exactly a million dollars per day, for every day in the year, including Sundays and holidays.

Compared with copper, the value of the gold and silver production in the United States is as a minor fraction, great as is the output of the precious metals, and rapid as has been the increase in production of the money metals by the mines of America. Another fact of deep interest is found in the surprisingly large percentage of the gold and silver output of the country that comes, as a by-product, from the copper mines. The vast and rapidly increasing value of the copper output of the United States, which makes more than half of the copper produced in the world, is a most significant development.

THERE is good reason to suppose that the first principles of microscopy were known in very early times. Layard dug up a convex lens of rock-crystal among the ruins of Nineveh, and it is practically certain that the exquisite gems of the ancient world could not have been cut in their minute detail without some such aid.

THE inclination and ability to view a question from the historical standpoint is of the same importance in the education of the scientific investigator as is the inclination and ability to do careful and conscientious experimental work.

Tredinnick's Process for Desilverizing Lead.

Written for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

The Pattinson process is based upon the fact that when lead containing silver (base bullion) is melted in a large kettle and is afterward suffered to cool to a temperature near its melting point, small crystals begin to form in the molten metal which, as they are produced, sink to the bottom, and, on being removed, are found to contain about half the silver of the original lead, the rest having been retained by the still liquid metal. If the crystals are removed to an adjoining kettle, melted, and the process repeated, crystals of lower grade are again obtained, and thus by using a series of kettles for the successive separations we finally obtain a market-lead almost silver-free. On the other hand, the still fluid alloy of the original pot treated in successive kettles on the opposite side may be gradually enriched up to 500 oz. silver per ton. This enriched product may then be treated by the Parkes process for a rich lead of 5 to 10% silver and the rich lead cupelled to obtain silver bars or ingots.

The Luce & Rozan improvement on this process consists in the use of high-pressure steam, whereby the lead is effectually stirred and the contained impurities oxidized. At the same time, water is sprinkled on the surface of the charge, quickly cooling the mass to the critical temperature for the formation of crystals. Moderately soft base bullion, up to one per cent in copper and antimony, can be refined by this method without preliminary softening; indeed the presence of those metals is rather an advantage, since they prevent undue drossing of the lead.

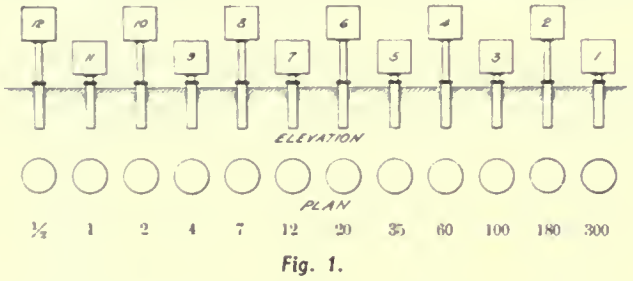


Fig. 1.

An improvement invented by Stephen Tredinnick consists in abolishing the melting pots and the steam cranes required to raise the base bullion (one-third liquid to add to the two-thirds crystals). In place of this, he uses a train or series of twelve crystallizing kettles of 50 tons capacity each. Each crystallizer is supported by a hydraulic ram, by which it can be raised at will, thereby enabling the lead to be run from kettle to kettle of the series as required.

Fig. 1 shows in plan and elevation the arrangements of the crystallizers, in which the kettles contain lead of the grade in ounces written directly under them in the plan. Beginning the operation, we will assume No. 2, 4, 6, 8, 10, and 12 to be full, ready to be crystallized and to be operated upon. The intervening crystallizers, 1, 3, 5, 7, 9, and 11 will be empty and already lowered to receive their respective charges. The one-third liquid from the crystallizer at the right and the two-thirds crystals from the adjoining kettle on the left complete the new charges. The one-third liquid from kettle No. 1 is discharged either directly to the zincing kettle or into molds for further treatment by the Parkes process. The two-thirds crystals in 12 are melted and discharged to be molded into market-lead. The odd-numbered kettles are now raised, treated by blowing through high-pressure steam and cooling with water to bring the lead to the temperature of crystallization. The even-numbered pots are then lowered in their turn to repeat the first maneuver.

Fig. 2 is a sectional elevation of one of the kettles with its hydraulic ram. The 50-ton kettle is shown surrounded by a brick-lined casing, within which circulates and burns the fuel gas, by which the kettle is heated. A steam pipe sliding through a gland gives a flexible connection to the high-pressure steam-supply, and this steam can be introduced beneath a baffle-plate, which distributes its flow evenly throughout the lead. The cover has a central opening for the escape of the fumes and hinged covers by which access may be had to the sides of the kettle for removing a crust formed

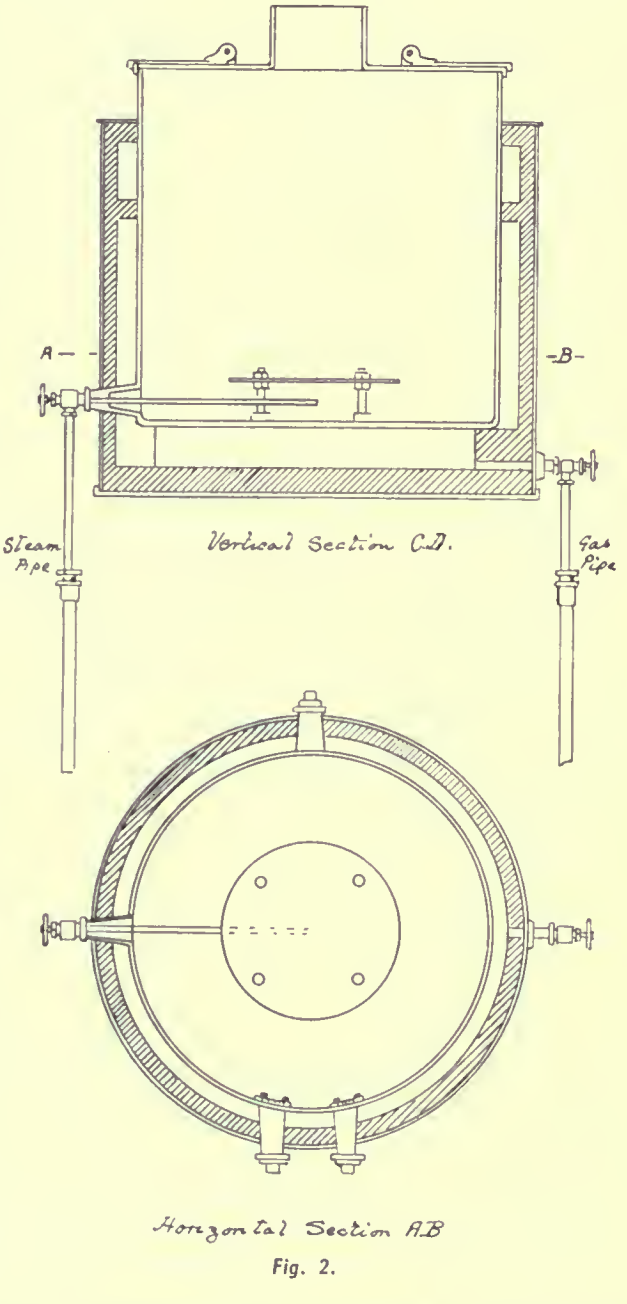

Fig. 2.

during the steam-poling. The outlet at the left has a strainer on the inside to prevent escape of the crystals, while at the right the crystals having been melted flow away freely.

The cost of a single operation may be thus given:

Fuel gas—10,000 cu. ft. at 5c. per 1,000	$0.50
Labor for one operation (for 12 operations, 3 men @ $3 $9)	0.75
Superintendence for one operation ($6 per day for 36 operations)	0.17
Steam for crystallizing	0.05
Tools and repairs	0.10
General expense	0.20
Total	$1.77

The stock of lead needed for the series is 300 tons. Low-grade bullion can be treated more easily and cheaply even than that of high grade. Thus Missouri lead, con-

taining one or two ounces per ton, could be treated at a profit. The lower the grade the fewer the operations necessary to arrive at the No. 12, so the cost of refining will be proportionally cheaper.

Thirty-three tons of 300-oz. base bullion can be desilverized in 12 operations, so we have $\frac{1.77 \times 12}{33} = 64c.$ per ton. The above is calculated upon the basis of receiving the fresh lead in a molten condition from a storage pot where it has been melted. To the 64c. must be added the cost of molding the market-lead. The desilverizing of the final 500-oz. product must also be added.

Pattisonizing is the most satisfactory method of treating lead containing bismuth, which is not removed in the Parkes process. On account of the low temperature at which the process is carried on, there is a gain in silver of from two to four per cent. In treating reasonably clean base bullion containing no more than one per cent of antimony, these metals are no drawback to refining, so that the total of dross produced is even less than that made in the Parkes process.

Mr. Tredinnick operated the Luce & Rozan process for upward of ten years at Eureka, Nevada, and his improvement is the result of extended experience.

Mr. Tredinnick himself says: "The number of operations necessary to enrich and impoverish the bullion is the same with the different methods, namely, concentrating a portion to 500 oz. silver and impoverishing the larger portion to one-fourth of an ounce of silver per ton. With the original Pattinson method, using kettles with 10 to 15 tons capacity, they performed from three to four operations per 12 hours. With the Luce & Rozan method and employing the largest kettle, we performed five operations per 12 hours. The time required to crystalize and run off the liquid was 20 minutes; we then had to wait nearly two hours for the melting of one-third liquid of a previous series of the following grade to add to the two-third crystals to re-fill the kettle to be operated again. With my improvement, using a kettle of 50 tons capacity and allowing 40 minutes to perform an operation, we can complete 12 operations per eight hours.

We aim to keep the bullion at as low a temperature as possible all through the several operations of the series. The bullion is just hot enough to skim clean; when skimmed the steam enters at the bottom of the kettle and two jets of water play on the surface of the bullion. It takes about 20 minutes to do the work, that is, to get two-thirds of the contents of the kettle into a crystalline state and run the one-third liquid into the adjoining kettle on the left. The workman shuts off part of the steam and water two or three times during the operation, while he cuts down the lead that has splashed around the upper part of the kettle. When the one-third liquid is run off, the valves are closed; the crystals are then melted and moved into the adjoining kettle on the right, to be mixed with the liquid from the next higher number kettle.

The liquid is run off in one direction of the series and the crystals in the opposite—the liquid toward the No. 1 kettle and the crystal toward the No. 12.

With high-grade bullion, say, from 200 to 300 oz. silver per ton, two crews of three men are required to operate the series. With low grade, say, lead containing from half an ounce to 20 oz., only one crew of three men will be required."

It would appear that little has been done of recent years in attempting to treat low grade bullion or the large output of Missouri lead containing a few ounces of silver, and that large profits await those who would undertake to treat such material, as well as such scrap-lead as contains silver.

Production of Chlorine From Salt.

It may be of interest to millmen who use chlorine in the extraction of gold to know that during this year the West Virginia Pulp & Paper Co., has been using the Hargreaves-Bird electrolytic cell at their Piedmont works in West Virginia under license from the General Electrolytic Parent Co., Ltd., of Middlewich, England, which is the owner of the American patents. The West Virginia company adopted this process after testing other methods and is now enlarging its plant. The Hargreaves-Bird cell is 5 ft. high and 10 ft. long, it has one set of anodes made out of gas carbon and two sets of metallic cathodes; the cathodes are separated from the anode by diaphragms that permit the sodium to pass to the cathode but do not allow the chlorine or the brine to pass through. The particulars given below of the work done in the month of May, 1906, at Piedmont with 16 cells, will enable engineers to work out the cost of production of chlorine at their own mines.

Amperes	2,600.00
Volts	56.92
Volts per cell	3.56
Electric horse-power used in cell room	198.50
Total electric horse-power used by plant	270.00
Steam used boiler horse-power	24.70
Current efficiency	90.00
Na_2CO_3 (soda ash) produced in 31 days	120,900 lb.
Chlorine gas produced in 31 days	81,511 "
Limestone used to produce CO_2	217,758 "
Coke used to produce CO_2	31,000 "

Each cell produces chlorine equivalent to 469 lb. of 35% bleach per 24 hours, also 243.7 lb. carbonate of soda. The cost of each cell, including royalty in England, is about $1,000. Repairs on a Hargreaves-Bird plant amount to about $1.25 per ton of bleach produced. The advantages of chlorine gas without lime (as in bleaching powder) for gold extraction are obvious.

THERE are some differences to be noticed in the various sciences. In the natural sciences the current periodicals contain a complete record of the direct progress of research. In comparatively few instances are new facts and thoughts first confided to the pages of a book. When the investigator wishes to study the literature of any subject he usually confines his search exclusively to these periodicals, and uses books only when he hopes to find in them more or less of the required information already compiled. In the science of medicine the method of procedure is in general quite similar, although the results of original researches are not infrequently published in book or pamphlet form. The other sciences may be arranged in a series in which this preference for the journals becomes less and less marked, until in the case of philosophy the other extreme is reached where the book has the upper hand. There appears to me, however, to be a noticeable movement toward the first mentioned state of affairs. This change is above all things being brought about by the fact that at the present time it is becoming more and more necessary for each scientist, on account of the active competition in his field, to publish his results as quickly as possible in order to obtain credit for them. This result is most easily obtained by means of a short magazine article. This also explains the extraordinary volume of the scientific literature of the present day; for in addition to heavy gold particles, from which later will be made valuable coins and beautiful ornaments to add to the intellectual wealth of mankind, it also contains unproductive material in great quantities, which will be swept away by the current of time, while the grains of gold remain.

A STATEMENT of the value of the various industries in Alaska shows that the fisheries lead all others, the production from 1878 to 1905 aggregating $96,000,000.

An Adaptation of the Stadia to Small Scale, Reconnoissance Surveys.

Written for the MINING AND SCIENTIFIC PRESS
By R. H. CHAPMAN.

During the progress of reconnoissance surveys recently undertaken by the writer, it became desirable to meander certain streams in order that they be mapped accurately enough to tie them to the corners of United States Land Surveys, and to locate houses along the valleys. The region was open, rolling prairie, entirely devoid of timber, of comparatively low relief except in such portions

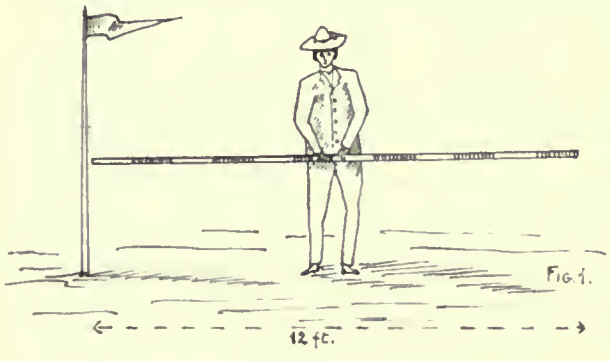

Fig. 1.

as were marked by the feature of cañons cut through a plateau, which was represented by remnant mesas rising in places about 300 ft. above the stream.

The usual method of wheel traverse would have been adequate for the horizontal factor, but to obtain elevations the aneroid ordinarily used in such work was eliminated on account of a high daily range, from one-tenth to three-tenths of an inch, and by irregular and abrupt changes due to local thunderstorm conditions and heavy winds. At the scale used, one inch to four miles, a fortieth of an inch equalled one-tenth of a mile, or 528 ft., and as platting to one-eightieth of an inch, 264 ft. was as close as could be accomplished, extreme accuracy was not necessary. The rod used was of the 12-ft. jointed variety, painted red and white in alternate foot-lengths. The telescope of the instrument was of the form ordinarily in use by the Geological Survey, which is so arranged as to turn 180° in the barrel carrying the trunnions, in order that adjustment for errors in colimation may be made without removing it from the Ys, and it has stadia wires in the ratio of 1 to 100. In using the instrument in the usual way, the limiting sight-length was 2,400 ft., using half the stadia-wire interval, and this was too short to be economically available, since the possible mileage per day was not warranted for the scale of work. The rodman worked on horseback and therefore a much longer rod was impracticable. He was supplied with a flagged range-pole, with a long slender iron spike in one end. Upon reaching a rod point, the range-pole was placed vertically and so maintained by the long spike thrust deep into the ground, and the rod was held horizontally with one end against the range-pole. The telescope of the instrument w turned 90° in the longitudinal axis, the stadia wir becoming vertical, and in sighting the rod one wire was placed so as to co-incide with the vertically placed range-pole. If the half-interval wire cut beyond the end of the rod (if the distance to be measured was more than 2,400 ft.) the rodman was signaled and measuring the rod-length on the ground, he held the rod *one length* further from the range-pole. (See Fig. 1 and 2).

This was repeated until the half-interval wire cut the rod, when by means of having counted the number of times that the rod was moved and adding that part of it included on the range-pole side of the wire, the distance was obtained and recorded.

Elevations were measured by vertical angles in the usual way, as the rod was horizontal and held at about the height of the instrument, and the horizontal wire was placed on the rod, the corrections for H. I. and slope, were elimiuated.

In this way many miles of line could be run in a day without appreciable error, and reasonable checks in height made. The longest sight so far made is 7,800 ft. and the best day's run about 12.5 miles, with an elevation check within 10 ft. This is as close as necessary, the contour interval being 50 ft. With practice and by doing away with the necessity of each day returning many miles to camp, there is no reason why the stadia party, instrument man and rodman, should not make 20 miles a day in such open country as that in which the method originated.

Great accuracy is not claimed for this method, but for reconnoissance work it is all that is desirable.

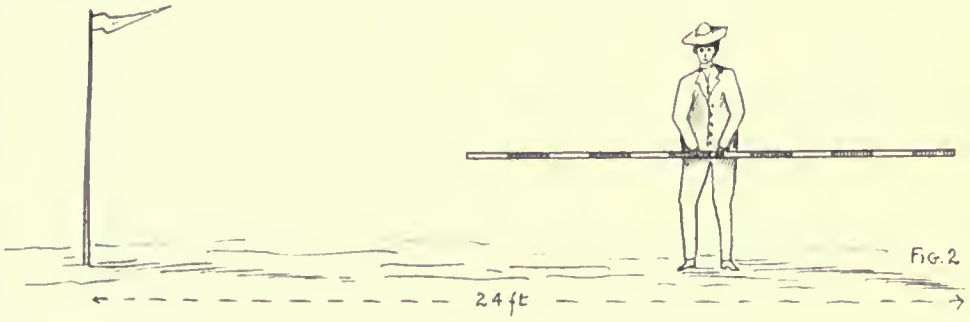

Fig. 2.

MECHANICAL APPLIANCES must have been adopted at a very early period, otherwise the huge blocks of granite quarried at Assouan, many of them varying from 18 to 60 tons weight, could not have been transferred and erected at the Pyramids, etc. To what extent these appliances were based upon actual scientific knowledge it is difficult to say, but, in any case, engineering may reasonably lay claim to being one of the learned professions from about 400 B. C., when Archytas, the reputed inventor of the screw, who died about 391 B. C., and Eudoxus, who died 352 B. C., both of whom were geometricians and philosophers, turned their thoughts to mechanics; but Plato inveighed against them with great indignation as corrupting and debasing the excellence of geometry, and making it descend from the intellectual to the practical; so that for some time applied mechanics were despised by the philosophers, and considered as simply a branch of the military art. The ancient philosophers esteemed it an essential part of learning to conceal their knowledge from the uninitiated, as they considered its dignity was lessened; and even went so far as to regard the introduction of mechanical subjects into the region of philosophy as a degradation of a noble profession.

WHEN capitalists are numerous and capital is abundant, work is plentiful and wages are high. Capital and labor are Siamese twins which can only be separated by killing them both.

An Electric Storm.

The accompauying illustration of an extraordinary lightning flash and thunder-cloud, we owe to Mr. A A. Forbes, who took the origiual photograph at 9 P. M. on July 25, 1906, at Bishop, Inyo county, California. It is an impressive display of atmospheric electricity and suggests destructive power. We are not informed that anyone was injured on the occasiou of this wonderful manifestation of energy.

It is 167 years since Benjamin Franklin identified the lightning flash with the electricity developed by a frictional machine. He used his celebrated kites to study the electrification of the air, the kite being provided with a sharp-pointed wire to "draw the electric fire from" the thunder-clouds. In later experiments with more refined methods, McAdie and Henry "obtained potentials as high as 3,000 to 4,000 volts, just before the lightning." Some of the latest experiments were made on the top of the Mills building in San Francisco, the roof of which was (before the earthquake-fire) covered with bitumen, so as to be a good insulator*.

From 700 to 800 lives are lost each year by lightning stroke, say, 1 person in 100,000. Such fatalities are more numerous in the Eastern States, for thunder-storms occur with frequency over all the area east of the one hundredth meridian; west of that meridian, except in the Rocky Mountain region, the frequency of lightning stroke diminishes, reaching a practical zero along the immediate Pacific coast. The region most subject to them is that of the middle Atlantic States.

One of the best explanations of lightning is that of Mr. Alfred J. Henry, professor of meteorology, as given in Bulletin No. 256 of the U. S. Weather Bureau. He says:

"We may, perhaps, better understand the phenomenon of a lightning flash by noting the similarity between it and the discharge of a Leyden jar. The Leyden jar, it may be remembered, consists of a glass jar, coated both inside and out with tin foil for about four-fifths of its height. The mouth is closed by a cork, through which passes a metallic rod, terminating above in a knob and connected below with the inner coating, usually by a chain depending from it. The two coatings of the jar obviously serve as collecting and condensing surfaces and form, in connection with the glass jar, what is known in electrical terminology as a condenser. The capacity of a conductor may be enormously increased by bringing near it another conductor connected with the earth. This process is called 'condensation of electricity.' If the inner coating of a Leyden jar be connected with an electrical machine and the outer with the earth, the former will acquire a positive and the latter a negative charge. If now a metallic rod be brought near the two surfaces of the jar, a spark is obtained whose power depends on the potential of the iuner coating and on its electrical capacity.

"If the jar has not been charged beyond its capacity, it will retain its charge, under favorable conditions, for many days. If, on the other hand, the inner coating has been too highly charged, partial discharges, invisible except as a phosphorescent glow in the dark, will occur from the inner to the outer coating until equilibrium is restored. Again, if a jar be subjected to a sudden rush of electricity it will overflow, that is to say, sparks will pass along the glass from the inner coating up over the lip of the jar and down the other side to the outer coating. Thus, we have seen that the overcharge of a jar may be dissipated by weak, partial discharges and also by a true spark discharge of some violence. The analogy between these two forms of discharge and what occurs in nature may be better conceived when we consider the layer of clouds as one coating of the jar and the surface of the earth as the other, while the air between takes the place of the glass of the jar. The glass of the jar, or in fact any insulating substance between two charged surfaces, is called the dielectric, and it is this dielectric of non-conducting air between the clouds and the earth that we live.

"In ordiuary fine weather the upper regions of the atmosphere are at a different potential from the earth, but the difference in potential or pressure, if we may use the last term, is not great enough to produce a discharge. The sparking distance is too great, and, as in the case of the Leyden jar, no discharge will take place so long as the electrical tension remains unchanged.

"It is well known that certain conditions of temperature, atmospheric pressure, and moisture favor the development of thunderstorms. Under such conditions the potential difference between the cloud on one hand and the surface of the earth on the other is increased, not gradually and for some time in advance of the thunderstorm, but rather suddenly, and more often locally than simultaneously over a large extent of territory. The cloud serves as a condenser of enormous extent, as compared with those used in laboratory experiments, but, nevertheless, the amount of charged surface presented to the earth may not, in the case of summer thunderstorms, exceed a few square miles. We have then, following out the analogy between a Leyden jar and a flash of lightning, a few square miles of cloud as one coating of the jar, an equal area of land as the other, with the air between subject to stress or tension. As in the case of the overcharged Leyden jar, the tension may be relieved by invisible or silent discharges from the top of every rock, building, tree, wire or other metallic object within the strained field, as well as from the under-surface of the cloud. Discharges of this character may and do take place through the human body, especially on high mountain summits, where the discharge at times is so marked as to cause apprehension for one's safety.

"Up to a certain point the air is able to resist the stress in it due to the electrification of the cloud mass. Whenever the stress passes a certain limit, which may be called the breaking point, the air gives way; literally it is cracked from cloud to earth like a piece of glass as the bolt descends. While human foresight is able to say approximately when a flash will occur, it can not say where the air will give way first. The zone of danger is in general co-equal with the area of the storm cloud, although it sometimes spreads out some distance in front of the storm cloud. Almost any upright object in this area is a better conductor than the air in which it stands. The wonder is therefore not that so many persons and objects are struck, but that so many escape.

"The ability of an electric current to break down a core of non-conducting air, depends upon its electro-motive force. A current of 10,000 volts will jump across a space of about half an inch of common air, and hence it has been concluded that a flash of lightning that extends from cloud to earth must have an electro-motive force of many millions of volts. Since many thunderstorm clouds are at least a mile above the earth, we must continue to marvel at the source of the tremendous energy involved in a single thunderstorm.

"The underlying causes of the electrical manifestations in a thunderstorm have not been clearly defined. It is known, of course, that the normal electric field of fair weather becomes disturbed concomitantly with certain other changes in the meteorological conditions, but no such relation as that of cause and effect has as yet been discovered. It is also well known that certain conditions of heat, wind, and moisture are present in the formation

*Lightning and the Electricity of the Air' by Alexander G. McAdie and Alfred J. Henry. Bulletin No. 197, U. S. Weather Bureau.

of thunderstorms, and it is, therefore, suspected that motion of some sort, whether mechanical, as of the wind, causing friction between the air particles, or molecular, as when water vapor is condensed into a liquid, is in some way the antecedent of the disturbed condition of the normal electric field. That there is some connection between the condensation of aqueous vapor and the electrical state of the atmosphere seems quite probable, but just what the relation is does not yet appear. The writer has observed the transformation of a plain cumulus cloud into a thunderstorm on more than one occasion. Rain almost invariably began before there was any other display of lightning whatever. The first manifestations of the latter were usually in the form of light thread-like discharges within the cloud, without audible thunder. As the rain increased and the wind freshened, the electrical discharges became more marked. These observations, though quite fragmentary, evidently indicate that the electrical tension of the air is increased by precipitation."

An Electric Storm at Bishop, California.

CALIFORNIA produces 200 to 250 oz. platinum each year, slightly more than half of it coming from the dredges at Oroville and Folsom.

The Volumetric Estimation of Antimony.

Written for the MINING AND SCIENTIFIC PRESS
By JAMES DARROCH.

All of the gravimetric methods of estimating antimony are tedious and many of them are unreliable, while the dry assay, although fairly expeditious, is notoriously inaccurate. When sodium thiosulphate solution is used for titration (as is generally the case) the iodide method cannot be relied upon, since the 'hypo' is decomposed, with the separation of sulphur, by the strongly acid solution that must be employed.

The method described herewith gives excellent results with all ores and alloys containing antimony, and it is much more accurate than any of the gravimetric methods, while it possesses the further advantage of being almost as speedy as the dry assay. This process is similar to the iodide method, the principal exception being that a standard solution of stannous chloride is substituted for the thiosulphate solution commonly employed in the titration. The means of getting the antimony into solution also differs from those usually adopted, hydrochloric acid (with the addition of tartaric acid) being much superior to hydrochloric acid plus nitric acid or potassium chlorate for this purpose, as not only is it more certain and expeditious than the latter, but it is also suitable for any ore of antimony, the presence of tartaric acid ensuring the complete solution of all compounds, whether sulphide, oxide, or oxychloride. Tartaric acid does not interfere, however, with the subsequent precipitation by sulphuretted hydrogen.

The determination of antimony by the iodide method is based upon the estimation of the iodine liberated when potassium iodide is added to a solution of antimonic chloride. It is essential for success that all of the antimony shall be present as antimonic chloride ($SbCl_5$), while free chlorine must be completely absent from the solution, which must be kept strongly acid.

The assay is conducted as follows: From 0.5 to 2 grams of the finely crushed ore, which should pass a 100-mesh screen, is dissolved in strong hydrochloric acid, with the addition of a few crystals of tartaric acid, heat being applied until no further action takes place. When the antimony is completely in solution, the assay is diluted to about 300 c.c. and a brisk current of sulphurretted hydrogen is passed through the liquor till it is thoroughly saturated. After the antimony has all been precipitated, the sulphide and insoluble residue are filtered off and washed two or three times with water containing sulphuretted hydrogen. The filtrate, which contains the iron, etc. present in the ore, may be discarded. The filtering and washing should be done as quickly as possible since the antimony sulphide is liable to decompose and again go into solution on exposure to the air.

The bottom is now knocked out of the filter, and the precipitate washed into a flask. About 100 c.c. strong hydrochloric acid, with the addition of a sufficient quantity of potassium chlorate to completely convert the antimonious chloride to antimonic chloride, is added to the assay, which is then boiled until the sulphide has dissolved. After free chlorine has been entirely eliminated the assay is allowed to cool, and when cold about 5 grams of potassium iodide is added to it. Iodine is liberated by the antimonic chloride in accordance with the reaction:

$$SbCl_5 + 2KI = SbCl_3 + 2KCl + I_2.$$

The assay will now assume a brown color, due to the iodine liberated, but should contain no precipitate, as antimonious chloride ($SbCl_3$) is soluble in strongly acid solutions. The solution is then immediately titrated with a standard solution of stannous chloride, and, during titration, the assay must be thoroughly shaken. The color is gradually discharged as the stannous chloride is run in, and when it has become pale a few cubic centimetres of freshly prepared starch solution are added, and the assay is well shaken. A deep blue color is at once produced, and the titration is continued until this is discharged. The end reaction is very sharp, even sharper than in the iodic method of determining copper, and, consequently, the titration should be done cautiously as this stage is approached. When the reaction is complete the assay should be quite clear except for the insoluble residue. The blue color generally reappears on standing a minute, but this is due to secondary decomposition, and may be disregarded; it is discharged by the addition of a single drop of the stannous chloride solution. The stannous chloride reacts with free iodine in the presence of hydrochloric acid thus:

$$SnCl_2 + I_2 + 2HCl = SuCl_4 + 2HI.$$

The volume of the standard solution of stannous chloride required for titration multiplied by the standard of same equals the weight of antimony in the sample taken for assay. Therefore the percentage of antimony present is found by the following calculation:

$$\frac{\text{Standard} \times \text{the c.c. stannous chloride solution required} \times 100}{\text{Weight of ore taken for assay.}} = \text{per cent of antimony.}$$

Since copper and arsenic also liberate iodine, and as bismuth iodide exactly resembles free iodine in color and would therefore interfere colorimetrically with the titration, these metals, if present, must be removed from the solution. The copper and bismuth may be separated by washing the combined sulphides on the filter with a solution of sodium sulphide, in which antimony sulphide is soluble (it is re-precipitated on acidifying with hydrochloric acid); the arsenic by boiling the sulphides of arsenic and antimony with strong hydrochloric acid, which does not dissolve arsenic trisulphide. Tin does not interfere, as, under the conditions, it would be present in the stannic condition only.

The solutions required for the assay are:

1. Standard solution of stannous chloride; this is prepared by dissolving 10 grams of stannous chloride in hydrochloric acid and diluting to a litre. This solution should be kept under paraffin as it oxidizes very readily.

2. Standard solution of antimonic chloride for standardizing; this is used to standardize the stannous chloride solution, and it is prepared by dissolving 0.2 gram of pure antimony in strong hydrochloric acid and potassium chlorate. This must be done in the cold, as the metal is almost insoluble in hot hydrochloric acid and potassium chlorate. When the antimony has dissolved, the solution is boiled till free chlorine has been driven off, allowed to cool, potassium iodide added, and titrated with stannous chloride in the same way as described for the assay. The antimony equivalent of the stannous chloride solution is found by the calculation: 0.2 gram antimony divided by the c. c. stannous chloride solution required for titration is equal to the amount of antimony (in grams) represented by each c. c. of the standard stannous chloride solution.

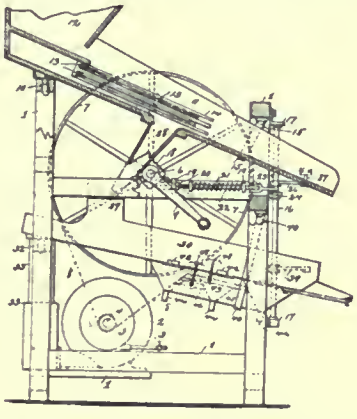
3. Starch solution; this is prepared as for the iodide method for copper. The solution must be fresh and entirely free from floating particles.

THE Bay Counties Power Co. is bringing down their electric lines from Colgate to Oakland across the Carquinez straits by the longest span in the world. The two steel supporting towers are 4,227 ft. apart, and carry four wires of $\frac{7}{8}$ in. stranded steel cable, three of them being used for current transmission, while the fourth is kept for a spare. The pull on each cable at its anchorage is about 12 tons, and necessitated the design of special insulators to withstand this strain and give insulation at the same time.

MINING AND METALLURGICAL PATENTS.

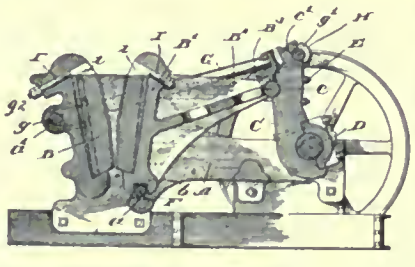
Specially Reported for the MINING AND SCIENTIFIC PRESS.

APPARATUS FOR SEPARATING METALS FROM ORES.—No. 839,329; William Snee, West Elizabeth, Pa., assignor to John A. Snee, West Elizabeth, Pennsylvania.



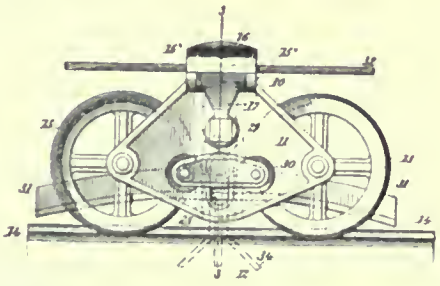
In a separating apparatus such as described, the chute 30, having an oscillating lateral movement, transverse openings formed in the bottom of said chute, slide-valves operating to regulate the area of said openings, in combination with an air-blast directed over and at right angles with the openings, as and for the purpose described.

CRUSHING-MACHINE.—No. 839,103; Morton G. Bunnell, Chicago, Ill., assignor to Western Wheeled Scraper Co., Aurora, Illinois.



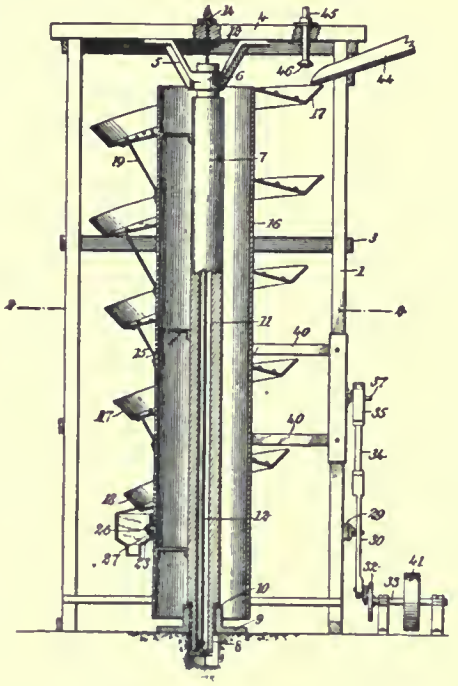
A jaw-crusher comprising a bed or body, a hopper formed in part by a movable jaw, a supporting-roll interposed between the bed or frame and the body of the said jaw, a pitman for actuating said jaw and connected with the latter at a point practically or substantially on a level with top of the jaw, and thereby above or substantially above the lines of resistance, and a swinging yoke having one end tied to the pitman and the other end tied to said bed or frame, said yoke thereby adapted to sustain both tensile and endwise compressive strains during the operation of the crusher, and a roll, yoke, and pitman combining to give the jaw a combined oscillatory and bodily forward-and-back movement, the said roll constituting an antifriction supporting bearing upon and about which the movable jaw is tilted or oscillated by the said pit man.

CLUTCH FOR AERIAL ROPEWAYS.—No. 840,109; Giulio Ceretti, Milan, Italy.



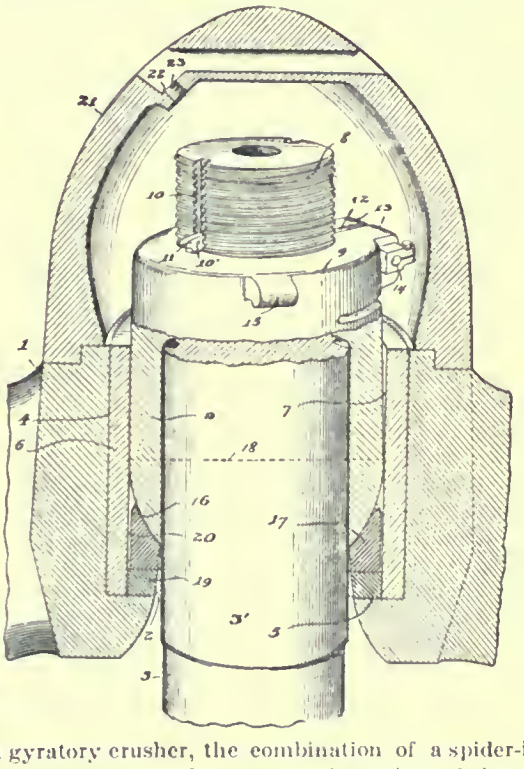
The combination with a rail or other support, of a coupling comprising a carrier-truck, adapted to ride thereon, clutch mechanism on said carrier-truck comprising a fixed jaw, and a movable jaw adapted to engage a traveling cable, a reciprocating link connected to said movable jaw, and a vertically movable member, adapted to sustain the load conveyed, co-operating with said reciprocating link to actuate said movable jaw, substantially as specified.

ORE-SEPARATOR.—No. 840,354; Matthew R. Lyle, Oakland, California.



A separator having a chute diminishing in sectional area toward one extremity thereof, and means for agitating said chute, said chute presenting an overhanging edge throughout the length thereof, whereby the waste material is constantly ejected from said separator as it progresses downwardly.

GYRATORY CRUSHER.—No. 839,891; Jay B. Rhodes, Chicago, Ill., assignor to Austin Manufacturing Company, Chicago, Ill., a corporation of Illinois.



In a gyratory crusher, the combination of a spider-head bored to accommodate the upper end portion of the main gyratory shaft, a supporting ledge or shoulder upon the interior of said spider-head, a main gyratory shaft, a wearing-sleeve mounted upon the upper end portion of said main shaft, and extending both above and below the centre of gyration of said shaft, the lower end of said sleeve being formed with a convex upper surface projected from a centre substantially coincident with the centre of gyration and supported by the said ledge or shoulder of the spider-head.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

It is without doubt the rule that the rights of a subsisting senior locator of mineral land are paramount to those of the owner of a junior location, so far as the latter conflicts with such prior location. It is equally plain that the power conferred by the United States statute, to re-locate a forfeited mining claim, does not place the locator in privity of title with the owner of the prior or forfeited location. In a conflict between locators the Court put the question and decided the principle thus: "The question then is, where there was a conflict of boundaries between a senior and junior location, and the senior location had been forfeited, has the person who made the re-location of such forfeited claim the right, in adverse proceedings, to assail the title of the junior locator in respect to the conflict area which had previously existed between that location and the abandoned claim? To say that the re-locator had such right involves, necessarily, deciding that as to the area in conflict between the junior and senior locators, the junior could acquire no present or eventful right whatever, and that on the abandonment or forfeiture of the senior claim, the area in conflict became, without qualification, a part of the public domain." After quoting Section 2,326 of the Revised Statutes of the United States, the Court added: "This section plainly recognizes that one who, pursuant to other provisions of the revised statutes, has initiated a right to a mining claim, has recorded his location notice, and performed the other acts made necessary to entitle to a patent, and who makes application for the patent, publishing the statutory notice, will be entitled to a patent for the land embraced in the location notice, unless adverse rights are set up in the mode provided in the section. Thus clearly providing that if there be a senior locator possessed of paramount rights in the mineral lands for which a patent is sought, he may abandon such rights and cause them in effect to inure to the benefit of the applicant for a patent by failure to adverse or after adversing, by failure to prosecute such adverse." The conclusion of the Court was that the area conflict between the two locators did not upon the forfeiture of the senior locator become unoccupied mineral lands in such manner as to enable a re-locator of such forfeited location to adverse successfully the application for a patent by the junior locator.

Lavagnino *v.* Uhlig, 25 Sup. Ct. 716.

It is essential that at the date of a location the ground located should be a part of the public domain. And it has been decided that an amended re-location made after the land had reverted to the public domain could not cure any defect in the original location from the fact that the land was not then subject to entry, where the rights of other persons had intervened. Thus it was said that one end of a lode-mining claim, which was separated from the rest of the claim by a patented placer claim, did not revert to and become a part of the public domain and as such subject it to re-location, until the claimant elected to retain and patent the north end of the claim, although such election was not made within the 60 days given for that purpose by the Land Department in refusing a patent for the entire claim for the reason that it was divided by the placer claim, but was deferred until after the unsuccessful termination in the Land Department of a contest with the placer claimant, begun after the decision refusing the patent. And it was further decided that the election to retain the north end of such lode-mining claim took effect instantly as an abandonment of the south end although the entry as to such tract had not then been formally canceled.

Brown *v.* Gurney, 26 Sup. Ct. 509.

The rule is established by the courts generally that the interest in a mining claim, prior to the payment of any money for the granting of a patent for the land, is nothing more than a right to the exclusive possession of the land based on conditions subsequent, a failure to fulfill which forfeits the locator's interest in the land.

Helena Gold &c. Co. *v.* Baggaley, (Mont.) 87 Pac. 455.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The mineral sent by A. H. F., of Dillon, Mont., is massive brown Garnet.

The brownish gray octahedrons from the Silver Top mine are Cerargyrite, or Hornsilver.

The mineral from Copperopolis, Cal., marked H. W. R., is commonly called Mountain Leather, a variety of the amphibole asbestos.

The yellow crystals from the Metalline mining district, Stevens county, Wash., marked J. H. H., are Wulfenite, the molybdate of lead.

Specimens from J. C. H., of Auburn, Cal., are No. 1, altered Gneiss; No. 2, Quartz; No. 3, Schist; No. 4, lignitic Coal; No. 5, Calc tufa.

The scaly material sent by J. B. G., of Dragoon, Ariz., is Mica and not molybdenite. The latter is darker lead-gray and metallic, resembling graphite.

The specimens from Villa Grove, Colo., marked F. S. C., are: No. 1 and 2, Quartzite containing pyrite crystals; No. 3 and 4, Chalcopyrite with some zinc-blende.

The stout prismatic crystals from the Desert Queen mine, of Tonopah, are Stephanite and the flat tubular ores are probably Polybasite. Stephanite and polybasite are difficult to distinguish apart.

THE MANAGEMENT of the North Star mines, at Grass Valley, in Nevada county, California, announced, on Christmas day, its intention to grant the eight-hour day to its employees. Mr. A. D. Foote, the manager, said: "On the first of the month the company has agreed to give the men the eight-hour working day. The men will start to get ready to go down at 6:45 in the morning and be ready for work at 7:15. They will work till 12, take half an hour for luncheon and then work until 3:45, when they will start to come on top. The night shift will all be down at 4:15, work till 9 and then take half an hour off for luncheon. It will quit work at 12:45. After the last man is out, a separate blasting force will attend to this part of the work and save you from eating a lot of powder smoke and dust. This, I think, will make things easier for you, add considerably to your lives, and at the same time enable us to mine as cheaply as now."

THE FOUNDATION CO., of New York, is engaged in sinking a shaft at the Syracuse, a Pickands-Mather company. The method used is entirely new on the Mesabi range, and is similar to that adopted in sinking caissons for buildings in the large cities. The work of concreting the walls of the old shaft at the Syracuse down as far as the water-level has been completed. A roof of concrete is now being constructed across the shaft at the water-level. Through this roof is set a section of air-tight circular steel shafting through which compressed air is admitted to the workings below the roof and through which the workmen will descend and ascend to and from their work. The steel shafting will be built in sections to the top of the shaft and capped with the section that contains the trap-doors through which the men enter and leave the shaft.

Geological Exploration in Alaska.

During the past season, the United States Geological Survey had numerous parties at work in Alaska. Their investigations covered a wide area, including the Glacier Bay region and Chichagof Island in southeastern Alaska, the Yakutat Bay region, the Controller Bay region, the Sushitna Basin, the Fairbanks and Kantishna placer districts in the Yukon-Tanana region, the valleys of the Yukon and the Porcupine and Seward Peninsula.

In the latter part of June, Mr. Alfred H. Brooks, chief of the Division of Mineral Resources of Alaska, joined Mr. E. M. Kindle at Eagle on the Yukon and remained with him three weeks, studying the stratigraphy of the section exposed along the Yukon River between Eagle and Circle. At Circle they separated, Mr. Kindle continuing down the river to the Porcupine and Mr. Brooks going overland to Fairbanks. This journey of about 200 miles, made on foot and alone, was accomplished in about two weeks. Subsistence and lodging were obtained at the different road-houses, as Alaskan taverns are called, or when these were lacking, at the prospectors' cabins and camps.

During the course of the journey a hasty survey of the Birch Creek placers was made. These placers, which have been continuous producers, are still being exploited. As they lie between 30 and 50 miles from navigable waters on the Yukon, the cost of all supplies in the district is enormous. Wages are from $6 to $7 per day, with board, which is counted as worth $3 per day. Winter freight rates are from 6 to 8 cents per pound, while the cost of summer transportation from Circle to the diggings is from 25 to 30 cents per pound. With such excessive costs, it stands to reason that only the richest placers can be exploited. In spite of these adverse conditions, the Birch Creek district has produced from $200,000 to $300,000 worth of gold annually for a number of years. Could the cost of operating be reduced, many creeks might be worked which are now untouched. Plans have been formulated for the use of dredges in this district and a large group of claims have been secured on Eagle creek, which are to be worked by dredging methods. The unfrozen condition of the gravels on this creek is favorable to dredging methods. Other placers of the district are also under investigation by capitalists, with a view of determining the possibility of their exploitation by dredges.

Mr. Brooks reached Fairbanks in the latter part of July. This district, the largest placer gold producer in the Yukon Basin, suffered seriously because of a drought which lasted until the end of July. Nevertheless, its output in 1906 probably exceeded that of 1905, which was about $6,000,000.

At Fairbanks Mr. Brooks joined a party under charge of Mr. J. L. McPherson, engineer of the Alaska Road Commission. The party of five men and seven horses made its way westward from Fairbanks for the purpose of exploring a route for a trail to Nome. At present, winter communication between Fairbanks and Nome is by Tanana and Yukon rivers, but it is proposed to establish a more direct route which will probably shorten the distance 200 miles. This party reached the Yukon at the Rapids about the first of September. While en route Mr. Brooks was able to visit some of the more important placer-bearing creeks of the Rampart district. This district, too, suffers from lack of means of communication, but a road, now being built south from Rampart, and another, completed to Glenn creek from the Tanana, will do much toward cheapening the cost of mining operations.

Mr. Brooks reached Nome early in September, and there joined Messrs. F. H. Moffit and P. S. Smith, of the Survey, who were engaged in mapping in detail the areal geology of the Nome and Grand Central quadrangles. The geology of this field is exceedingly intricate, and very much time has been given to the collection of data in regard to the occurrence of gold in the placers. Mr. Brooks found that Nome had been exceedingly prosperous during 1906, in spite of the long drought which so reduced the stream flows in many parts of the Seward Peninsula as to almost prevent any mining on the creeks. Fortunately, the discovery of rich placers along an ancient beach lying about five miles inland, and running parallel to the present shore line, led to great activity, and, therefore, in spite of the adverse season, the gold output of the Peninsula in 1906 was over $7,000,000, and nearly $2,000,000 more than in 1905.

The value of geological investigation to the mining interests is well illustrated by the discovery of these ancient beach-placers. As early as 1899 and during the first gold excitement at Nome, the geologists of the Survey published a statement predicting the discovery of ancient shore lines and presented evidence that these would probably be found to carry commercial placers. These statements were borne out by later investigations, and it remained only for the miners to bring the final proof that the theories were correct.

Later, Mr. Brooks joined Mr. F. F. Henshaw, who, under the general supervision of Mr. John C. Hoyt, was engaged in studying the water resources of the Nome region. It is every year becoming more and more evident that the chief problem to the Nome placer miner is how to obtain an adequate supply of water. Stream gauging is, therefore, of the greatest possible value to the mining interests.

The latter half of September was devoted by Mr. Brooks to a reconnaissance of the more important placers of the Kugerok district. This placer field, which lies in the central part of the Seward Peninsula, has been exploited ever since 1900. Lack of capital has, however, up to the last two years, prevented the proper development of the placers, especially as the district has been very inaccessible. Recently, however, a railway has been built from Nome to Lane's Landing, at the southern margin of the district, and ditch building has been going on with feverish activity. About 40 miles of ditch have been completed, and other projects are under way. While some of these enterprises are hardly to be commended, yet there can be no doubt that mining operations will now increase with great rapidity.

ARTICLES ALLOWED IN INTERIOR ALASKA MAIL.—Articles allowed in the winter mail carried overland and intended for interior Alaska and Yukon points are letters, post cards, singly-wrapped newspapers, and periodicals from the office of the publication addressed to public libraries, newspaper publishers, and to individual subscribers, transient newspapers, and third class matter of all kinds, excepting books, trade catalogues, circulars, and patterns and samples of merchandise.

A letter is defined for post-office purposes as "any article of correspondence prepaid at letter rates and contained in an envelope, however large, which might be presumably used for enclosing a letter, and such documents as are from time to time sent under the same cover as letters." The articles excluded are periodicals sent to dealers for purposes of trade, in bulk or otherwise, sample copies, catalogues, books, circulars, samples of merchandise, and fourth class matter.

CAPITAL is result. Labor is effort. Capital is a product of previous effort, while labor is present effort.

A Powder Test.

The accompanying illustrations serve, to a certain extent, to show what a trifle over one pound of Aspco, the new safety explosive, will accomplish. In the upper photograph it will be seen that a drill-hole has been made in a boulder approximately 12 ft. in diameter, and in which but five

Tamping the Hole.

eight-inch sticks or cartridges of $\frac{7}{8}$ in. diam. have been loaded. It was intended to use nine or ten cartridges, but, as the bottom one became choked or blocked, it was possible only to insert five, which weighed slightly over one pound. There was some doubt as to the results on account of this

Result of the Blast.

light charge, but a glance at the lower photograph (after the explosion) demonstrates the wonderful energy and disruptive force of this new powder. The demonstration at which these photographs were taken was given at Los Gatos, Cal., on September 12, 1906, in the presence of a number of mining experts, and was satisfactory in every way. We are informed that this new explosive is guaranteed to meet all claims made by the manufacturers, The American Safety Powder Co., whose works are situated at San Jose, Cal. The sales manager of Aspco is George W. Myers, P. O. Box 135, Berkeley, California.

The Pelton Water Wheel Company.

The first modern machine-shop to be erected in San Francisco since the fire of last April, is that of the Pelton Water-Wheel Co., which is in the block bounded by Harrison, Alabama, and 19th St. This is now in complete running order. Although the company was completely burned out in its former establishment on Main St., it was fortunate in having, prior to the disaster, planned and contracted for its new works, and although the plant was erected under the emergency condiditions immediately following the fire, it is not a collection of temporary structures by any means, but of most substantial construction throughout. The design and equipment is the result of careful study, and for its capacity represents one of the best plants in the country today, being intended as the permanent home of this enterprising concern.

The main machine shop is 124 ft. 6. in. wide by 180 ft. long, and is devoted exclusively to machine-work on water-wheels and hydraulic accessories. The building consists of two bays, each 62 ft. 3 in. wide and 40 ft. high to the bottom of the roof-trusses. The columns of the main row consist of a 16 by 16 in., with a 12-in. timber on each side—spaced 20 ft. centres, each supporting one end of the roof-trusses. The 12 by 12 on each side of the 16 by 16 in. timbers are bolted through and form a double row of crane-track supports for one side of each bay. The crane-tracks of the main bay are placed 34 ft. above the floor, and the crane has the entire run of 180 ft., reaching within three feet of each side wall and five feet of each end wall, thus covering a floor area of about 10,000 sq. ft., and reaching all of the motor-driven tables. The second machine bay is equipped with a crane-track 20 ft. above the floor and running the entire length of the building. The main crane-track is on 24-in. I-beams and the secondary crane on 15-in. I-beams—all supported on the above mentioned 12 by 12 posts with 20 ft. centres. The second bay is arranged with the crane lower than in the main bay, admitting of a second floor being placed over the crane, thus affording space for the pattern shop, drafting room, and office. Separated from the main building by a 20-ft. driveway is a two-story pattern annex 62 ft. 3 in. wide by 75 ft. long, being an exact continuation of the second bay of the main shop, so that the main building may be continued to a depth of 275 ft. when desired. This building is fitted with an elevator for the convenient handling of large patterns to the second story. In the pattern annex there is a hydraulic laboratory of particular interest, now being fitted up with a special apparatus for the investigation of bucket and nozzle curvatures, provision being made for the constant gravity and pump pressures, prony brakes, chronographs, mercury gauges, electrical recording apparatus, etc. In this building is also placed, temporarily, a special bucket-milling apparatus for machining with mathematical accuracy, buckets for the Pelton water-wheels.

Commercial Paragraphs.

THE MINNEAPOLIS STEEL & MACHINERY CO. has recently opened an office at 1300 W. 11th St., Kansas City, Mo., under the management of Louis Bendit, for the sale of their Munzel gas engine and suction gas producer.

HENRY R. TOWNE, president of the Yale & Towne Mfg. Co., Stamford, Conn., at a meeting of its superintendents and foremen held recently, made announcement of an increase of wages and piece rates of its 3,000 employees, making a grand total of $120,000. This action is voluntary on the part of the company and is intended to recognize the industrial conditions now prevailing.

THE POWER & MINING MACHINERY CO., of Cudahy (a suburb of Milwaukee), Wis., in conjunction with The Snow Steam Pump Works of Buffalo, N. Y., has opened a new sales office at 719 White Bdg., Buffalo, where will be handled the several types of gas-generating apparatus, such as the Loomis-Pettibone system, suction and pressure gas plants, built by the Power & Mining Machinery Co., and the Snow gas engines, built by The Snow Steam Pump Works.

Editorial.

A GOOD DEAL of twaddle is being written about Mr. Simon Guggenheim, the new senator from Colorado. His resignation as a member of the executive committee of the American Smelting & Refining Company has no meaning, for he retains his financial interest in the company and as regards the management it is well known that Mr. Daniel Guggenheim is the dominating spirit at 71 Broadway. The new senator is an able business man and one of a large family of enterprising citizens, but his fitness as a legislator is a wholly unknown quantity. The method by which the election was secured indicates crude notions of civic duty, and it seems to us that in certain States, like Montana and Colorado, it would be better to put the senatorships up at auction; this would avoid the necessity for debauching the legislature and it would give the State another source of revenue.

THE dump at Stratton's Independence mine ought to go down in metallurgical history as a landmark, for it has been observed, tested, and tried by a succession of experts—Cassel, Hammond, Huntoon, Beatty, Doveton, Schroter, Merrill, and last, but far from least, Argall. A pile of 600,000 tons that will average $3.70 per ton represents a nice sum of money and if two-thirds of it can be turned into profit, as claimed, the famous old mine will add another $1,500,000 to the $5,000,000 that it has given to the shareholders. Just at present that famous dump promises to stimulate a battle of the processes, for vacuum-filters and filter-presses are pitted against each other, not to mention other modifications that may be thrown into the metallurgical show. Whatever the process, we hope the directors of the company may have the good fortune to get a maximum extraction at a minimum expenditure.

THE transfer of *The Argonaut* into the capable hands of Mr. Alfred Holman is an event in the journalism of the Pacific Coast that we are glad to record. Fifteen years ago Mr. Holman controlled the MINING AND SCIENTIFIC PRESS; more recently he has lived at Sacramento, where he edited and published *The Union* in such a manner as to enhance its value fourfold. Among Western periodicals *The Argonaut* won prominence long ago when edited by Frank Pixley, a clever eccentric who ended his journalistic career most ignominiously. Since then Mr. Jerome Hart has conducted the paper, without particular effect. Under the new direction it is likely to exercise an influence equal to its past reputation for trenchant literature, because Mr. Holman is a man of both character and ability; of the latter there is plenty on the papers of San Francisco, of the former there is precious little. That is why their attacks on municipal corruption are so ineffective and their descriptions of bestialities so copious.

Therefore we are glad to know that henceforth *The Argonaut* will give voice to the better thought of this community.

THE ARREST of Dr. R. C. Flower in Mexico recalls his successful swindling in New York a few years ago. He operated several mines in Chihuahua, all of which were absolute failures, and at the time when he became a fugitive from justice in 1903, he had just organized a Pan-American $15,000,000 corporation. His operations were stopped finally by suit brought by a widow, who had lost money in one of his ventures. There are many like him out of jail today, and the game he played is being worked enthusiastically by scores of similar swindlers all over the country.

IN REVIEWING the speculative spirit of 1906, we referred to the fact that Boston had escaped any spasm of excitement. This was only just true, for in the first week of 1907 there was a copper boom of a most lively character that gave the brokers of Boston the busiest time they have had for years. On January 4, 244,531 shares were sold on the Exchange, as compared to an average day of 50,000. Lawson's advertising campaign caused Trinity to be the basis for big dealings, 10,000 more shares being sold in ten days than there are shares in the company. All the big mines of Michigan, such as Calumet & Hecla, Oseeola, and Copper Range, scored a rapid rise and the disposition seemed to be to favor the properties so long familiar to the Boston public. A 25-cent price for copper explains much of the speculation, for the metal has appreciated so much as to ensure big profits to well-managed mines. The Lake Superior mines are among the best managed in the world and people who speculate in them are sure of a run for their money, but we hope that the Boston boom will keep within the limits of the safe and sane.

The Geological Survey.

The United States Geological Survey has recently received severe criticism in regard to its relations with educational institutions and State bureaus of geology. One of the first fruits of an aroused public opinion has been a prompt desire on the part of the Director, Mr. Charles D. Walcott, to meet the situation squarely. At his call, a conference of State Geologists has just been held at New York in connection with the annual meeting of the Geological Society. The difficulties of the situation are said to have been frankly discussed and methods were outlined for an exchange of plans and notes between the different surveys, State and National; it was also arranged to hold further conferences at regular intervals. The meeting made it clear that more personal contact is advisable between the officers of the Federal and the State Surveys, and it was impressed upon the Washington people that there is a real feeling of dissatisfaction that must be respected. A good understanding was reached, the need of strong State surveys was emphasized, and the co-operation of the chief of the Federal Survey was practically assured. This is news that it is a pleasure to chronicle.

The Survey seems destined for better days, it is shedding some of those departments that were devoted to wood, water, and arithmetic — appendages and encumbrances detrimental to progress. The Forestry work was turned over to the Agricultural Department by action of the Congress about eighteen months ago, and in July last year the Reclamation Service was severed from the Geological Survey, except that Mr. Walcott continued to act as director of both, by order of the Secretary of the Interior. It is no secret that Mr. Walcott really wants to be relieved of his responsibility as head of the Reclamation Service, and the latter will become a totally separate bureau at an early date. The division of Hydrography has had its name changed to Water Resources. It includes a broad study of an important subject, and the geological knowledge required of the men who conduct the investigation is held to bring it within the proper scope of the Geological Survey. It is a small affair as compared with the other activities of the Survey.

There remains the Statistical branch, which, in our opinion, is too prominent. To turn geologists of first-rate ability into amateur statisticians, and to label compilers of statistics as geologists, appears to us to be a blunder. Of course, a man familiar with the mining geology of California, for example, will collect mineral statistics and information concerning the distribution of the metals with more intelligence than a clerk or accountant, but it looks like waste of a rare kind of ability to set certain geologists, whom we need not name, to such a task. We hope the Survey will be able to subordinate this part of its work, so that the actual investigations of ore occurrence may not lose the services of some of the best men. The compilation of statistics is at the best an unscientific application of arithmetic, and we would like to see it kept in a subordinate position.

On the whole, as a friendly critic of the Survey, we take pleasure in acknowledging the tendency to shed the unessential, and to concentrate work on the main purpose for which it was organized by Clarence King. It is only fair to give the Director credit for great administrative ability and to recognize the fact that, for this reason, he has had thrust upon him, by the President and by the Congress, a multiplicity of duties, which have interfered with his work as a chief of geology. By reason of the usual ignorance of members of the Congress concerning the work of the Survey, it becomes necessary for the Director, and certain of his assistants, to make some sort of presentation of the facts relating to the conduct of their work. For this reason we hope that mining engineers and other professional men, most of whom are keenly interested in the welfare and continued usefulness of the Geological Survey, will take a little trouble to enlighten their representatives at Washington.

Since the above was written we have learned that Mr. Walcott has been chosen Secretary of the Smithsonian Institution, a post of much honor and importance in the scientific world. We await the name of his successor with keen interest, for the usefulness of the Geological Survey must depend largely upon the ability and policy of its chief.

By the Way.

In a recent issue of *The Evening Post*, of New York, there appeared the following discussion on the persistence of our present prosperity:

In the comprehensive review of the financial situation from a dozen great money markets of the world, the noteworthy fact was the unanimity with which assertion that prosperity is today unprecedented was coupled with a note of warning or misgiving. Various reasons, most of them vague enough, were assigned for this state of mind; in general, the dominant idea appeared to be that the trade activity incident to existing prosperity had reached such a pitch that neither capital or transportation could keep pace with it. One might trace, in these suggestions of doubt about the future, much the same feeling as inspired Secretary Shaw to advise prayers against any greater prosperity, or Mr. James J. Hill to declare that the railway situation of today threatens commercial paralysis. Both of these intimations were based on a state of things which nothing but extraordinary prosperity could have created.

The *Journal of Commerce* yesterday published the views of numerous economists and practical financiers on the question whether we are approaching a financial crisis. With prosperity admittedly at high notch, one might imagine such an inquiry to partake of the absurd; but the experts to whom it was put take it seriously enough, and do not agree in their answers. Professor Sumner of Yale asserts that in the economic outlook he "cannot see the slightest cause for apprehension." "In times of great prosperity," he proceeds, "speculation becomes over-confident and rash. I see no signs of any such error now." Professor Laughlin of Chicago University is not so sure. His comment is:

"In conclusion, there seems to be no immediate evidences of a crisis in the very near future. But no reform of our currency, no combination of large financial interests, will prevent the inevitable over-expansion in due course of time, which must finally be followed by liquidation. Even now the materials for overconfidence may be gathering. The speculation in real estate, which is usually the latest phenomenon of a high range of prices, is already more or less apparent."

Professor Clark of Columbia, remarking that if the familiar periodicity in panics is observed again, 1913 would be the year for the next one, concludes his review by predicting that "recklessness now—general infection with the virus of a speculative fever—will cause the crisis to arrive at its scheduled date and with all needed severity."

So much for the economic students; the practical men display similar variation of opinion, with, however, more unanimity in doubt as to the future. The most optimistic view expressed is that signs "point toward continuance of the prosperous times for at least another year." Mr. Stuyvesant Fish goes so far as to declare that "in point of time a great industrial crisis is due, and there are many indications of its being imminent"—among these indications being the dearness of money because of high prices, waste of capital, and decreased efficiency of labor; absorption in Wall Street speculation of an undue proportion of the country's capital, and growing distrust by the people of methods prevalent in the investment markets. Taken as a whole, the statements plainly show that all classes of the community are pervaded with the idea that a change of some sort, in the industrial and financial outlook, may not be very distant.

What is to be said of this? First, no doubt, that experienced men accept it as an axiom of trade that profits and volume of business never expand indefinitely, and that a check of some sort is apt to be sustained when it is manifest, as it is today, that the 'boom' has outstripped existing facilities of production, labor, transportation, and capital. To that extent, the judgment of practically all trained observers in the business world would doubtless be in unison. It is when the nature and severity of the possible reaction are considered that agreement ceases. 'Trade reaction' and 'industrial crisis' are by no means synonymous terms. We passed through an unmistakable trade reaction during the second half of 1903; the surest sign being that in the period monthly iron production was cut down one-half, in spite of which reduction unsold supplies increased nearly half a million tons. Yet this was scarcely a financial or economic crisis; nor could that term be fairly applied to the similar contraction of business during 1900. In neither episode was the great forward movement, characteristic of the first half of the 'cycle of prosperity,' seriously interrupted. Such a crashing-down of the credit structure as occurred in 1893, for instance, is a very different matter.

Reactions such as those of 1903 and 1900 will be frequently encountered; it is not at all improbable that the country has something of the sort not very far ahead. It would not be so easy to discern sure indications of a severe industrial crisis. More people than Mr. Fish have been made uneasy by the abnormal state of the past year's money market; and the assertion has been ventured, by both home and foreign bankers, that these phenomena, taken by themselves, closely resemble those which preceded the troubles of 1873 and 1890. But it may be alleged, on the other hand, that evidence of actual impairment or abuse of credit, as distinguished from mere overstrain on capital, was really the fundamental danger sign of those two years. It appeared as fully in commercial as in financial affairs; an entire community had not only been indulging in extravagance, but was involved in debt to an exceptional degree. It may be questioned whether the present situation provides a parallel; it certainly does not, so far as regards the absolute insecurity of the basis on which the 'boom' preceding each of those periods had at the end been exploited. For the rest, Professor Clark is probably wise in holding to the 'twenty-year interval' as a means of taking our present economic reckoning. If tradition is followed in this generation, we still have a half-a-dozen years to wait before the first-class crisis.

AMERICA is not yet a democratic country; it is moving along the road to democracy. Our fathers realized that they were entering on an experiment, and they were cautious. They adopted the political methods of the mother country modified to suit the new conditions. They dispensed with certain feudal inheritances, but they did not straightway establish a pure democracy. They did not trust the people to choose their President, but only to elect a body of wise men to choose one for them; nor to determine their national policies, but only to elect representatives to determine those policies for them. The nominations for the more important offices were made by their selected wise men; the votes which elected them were cast by a limited electorate.

Gradually the self-imposed shackles have been cast off. The suffrage has become approximately universal; the newly arrived immigrant had been given a share in the government after a very brief apprenticeship; the policies of the Nation are being determined by the people in public discussions, and the Congress is becoming a collection of committees to frame these policies in appropriate legislation. Debates are transferred from the floor of the Congress to the open forum and the press. The nominations are made by the people in popular conventions. Politically, the country is passing from a representative republic to a pure democracy.—*The Outlook.*

Special Correspondence.

Joplin, Missouri.

Output Increasing.—Mining in Sheet Ground.—Several New Strikes. —A Coal Discovery.—New Tract Opened for Prospecting.

The highest settling price reported paid for zinc ore last week was $50.50 per ton for one carload from the Golden Glow mine, a new one on the Underwriters Land Co.'s land at Webb City. In Joplin, several carloads sold at $50 per ton. The highest price reported paid for lead ore was $87 per ton for at least one bin in Webb City and also one in Joplin.

Shipments.	Zinc ore, Lb.	Lead ore, Lb.	Combined value, $
Past week	11,088,790	1,356,730	310,688
Up to date	22,259,370	2,981,230	632,850
Same period last year	21,091,540	2,309,840	578,425
Increase	1,167,830	671,390	51,425

This increase if maintained will mean an addition of at least $1,400,000 for the year.

A few years ago the mining of the sheet ground, now so extensively engaged in, was unheard of and when a mining company or the prospectors got down to the lime rock or very hard flint, it was thought they were at the end of mining that particular piece of ground and it was usually abandoned. With Eastern capital and mining men came the idea of going deeper and opening up the runs of ore that seem to underlie this entire mining district and the outlook for the year 1907 is that there will be more extensive sheet-ground mining than there has been in all the past five years together. It has been conceded by those acquainted with sheet-ground mining that the size of the profit is correspondingly large with the size of the mill, and a majority of the mills being erected on new prospects are from 300 to 500-ton plants. The sheet-ground development is being made very fast from Oronogo in a southeasterly direction through Webb City, Carterville, Prosperity, Porto Rico, Duenweg, Diamond, and on toward Granby. There are a few similar properties working in the west part of Joplin, having recently been opened up.

T. E. Allen, of Webb City, has made several good strikes of ore on the Quinby land, near Diamond, a 12-ft. run of zinc ore having been encountered in one drill-hole. L. A. Hatcher, of Webb City, reports a rich strike on his lease on the Lyon land, near Porto Rico. The run of ore was encountered at a depth of 165 ft. and continued down to 180 ft. Mr. Hatcher will begin at once to sink a shaft and develop the ground. Thos. Hill, one of the best known mining men in the Webb City district, reports a rich strike in a hole that he has just completed on an 80-acre tract, about a mile and a half west of Neck City. Mr. Hill struck the ore at about the 200-ft. level and it continued down to a depth of 262 ft. It is the first hole put down on the 80 acres.

Some Webb City parties have opened up a coal mine at a depth of 25 ft. on the Milton farm, near Alba. They have a 25-ft. vein, according to the showing of the drill. They are sinking a shaft for the purpose of finding out whether they have a coal mine or have just encountered a pocket, which is more than likely, as coal has been found in that locality for several years, but never in paying quantities.——The Ideal Mining Co., composed of T. F. Coyne and A. D. Hatten, of Webb City, and several New York capitalists, closed a deal yesterday for the 240-acre tract of land belonging to the Carter heirs. The land is situated just south of the west portion of Joplin. Several years ago, when ore was selling around the $20 mark, there was some mining done on the land and one mine, the Colorado, was a big producer, but of late years nothing has been done on the land. It will be thrown open for prospecting again. The deal was made through the Lyon Investment Co., and it is reported the consideration was $500,000.

Butte, Montana.

The Lewisohns Secure More Property.— Snowstorm Dividend is Passed.— East Butte Strikes Rich Vein.— A New Copper District.— Barnes-King Re-organized.— Copper and Gold Ores in the Cable Mines.— Butte & Superior Organized.

It is announced that the Lewisohns are about to organize a new company for the purpose of taking in several groups of mines and claims in the Butte district, including the mineral ground of the Great Northern Railway Co., which was incorporated under the name of the South Butte Mining Co. The Lewisohns recently secured an option on this ground and they have been exploring it. The same people are developing and exploring several properties in the district, and have options on half a dozen others. The proposed new company will be capitalized for $2,500,000.—— The Butte-Montana Co. has started to sink the shaft of the Alex Scott mine. It is 700 ft. deep and will be sunk to the 1,200-ft. mark. The company has copper ore at the 700, and expects to have a big mine at the 1,200. It is intended also to sink the shaft on the Annie. The latter claim is situated in the northwestern part of the Butte district, near the Goldsmith mine; it has a shaft 200 ft. deep, and at that depth some shoots of good ore have been opened.

Butte stockholders of the Snowstorm mine have received notice from W. D. Greenough that the January dividend has been passed, but that $45,000 will be distributed in February. "I had fully expected to start monthly dividends on the 10th of January, but owing to a number of circumstances over which I have no control I have been disappointed," says Mr. Greenough. "We have not received a carload of coal in five weeks, and this has caused a closing of the mill. In the last month we have been able to dispose of only the usual quantity of ore sent to the smelters. This is due, to some extent, to repairs on furnaces and the congested condition of traffic. The Snowstorm mine is developed to the point at which it should own its own concentrating and smelting plant. The condition of this particular district looks favorable for the erection of a smelter the coming summer. The mine is in shape to yield 2,000 tons of ore per day, and the company should provide for this output. Until some extensive arrangement is made to take care of the immense tonnage the mine is capable of yielding, the company will not be able to pay the dividends it should. Our ore is used almost exclusively for converter lining, and the different smelters that use it do not take any more of it than they require for this purpose. Hence we are likely to have our output curtailed at any time. We will pay a dividend of $45,000 in February, and if conditions are not too unfavorable we will be able to continue this dividend monthly."

The Butte-Milwaukee Co. has received the machinery for the new surface plant on the Colonel Sellers claim. Boilers, air-compressor, and engine have been delivered. The shaft is about 35 ft. deep and good progress will henceforth be made in sinking. Grading for the railroad spur to the shaft has been finished and the line will be completed in a few days.——The Davis-Daly Co. has ordered a new air-compressor for the Colorado mine. It will have a capacity of 25 drills. Sinking on the Colorado has been resumed. The shaft is 650 ft. deep. At the Smokehouse shaft, cross-cutting from the 500-ft. station will be started shortly.——In a west drift on a vein in the north cross-cut from No. 1 shaft of the East

Butte Co., a fine body of copper glance has been opened. The vein itself is about 12 ft. wide, and eight feet of it is high-grade ore, a foot of it being copper glance. The remainder of the vein is concentrating ore. The company is now regularly making shipments of ore independent of the many lessees working in the properties.

The Farrell Mining Co. has begun cross-cutting from the 200-ft. level of the Alliance shaft, and expects to cut the vein within a distance of 50 ft. —— The shaft of the Butte Copper Co., on the Trifle claim, has reached a depth of 500 ft., but 500 ft. more will be added to it before any extensive cross-cutting will be done. One vein that apexes in the Trifle ground has been cut by the shaft, and another, dipping from the Anselmo ground, is expected to be encountered soon. This vein was cross-cut and drifted on at the 500-ft. level, and was found full of ore.

A new copper district is being developed south of Butte in Beaverhead county, about 50 miles northeast of Dillon.

Montana.

The Park Copper Co., owned by Butte men, has been developing a property there for several months, and at a depth of 80 ft. cut a 12-ft. vein of good copper and silver ore. A number of prospectors and several companies are operating in the district and exploring the ground.—— The Barnes-King mines have been turned over to the new company, the Barnes-King Development Co., and a new lot of men are in charge. R. B. Lamb, of Berkeley, Cal., long connected with the Daly interests, is at the mines as consulting engineer for the new company, and W. K. Brule, an experienced gold mine operator, is in charge of the property as superintendent. N. A. Miles, formerly an instructor at Harvard, and son of General Miles, is geologist for the Barnes-King. It is the intention of the new company to double the output of the mines, increase the capacity of the mill, and spend about $400,000 in improvements and development.

The Butte & London Co. is cutting a station at the 800-ft. mark of its shaft on the Greendale. A large pump will be installed, and as soon as it is in position sinking will be resumed.—— The Cable Consolidated Mining Co., which was surprised several months ago when its diamond-drill penetrated a big copper vein while boring for gold deposits, has shipped several carloads of copper ore, which gave an average assay of 1% copper and good values in gold. In addition to mining copper, the company is operating a 20-stamp mill on its gold ore. The copper ore is shipped to the Washoe smelter at Anaconda. Some of the ore assayed as high as 11% copper.—— The shaft of the Colusa-Leonard Extension Co. penetrated bedrock at 220 ft. The bedrock is of greatly varying depth in that part of the district. The Colusa-Leonard found it at a depth of 225 ft., while in the Sinbad mine, 600 ft. north of the Colusa-Leonard, it was not found until the shaft had reached a depth of 417 ft. The Pittsburgh & Montana Co. struck it at 623 ft., its shaft being a short distance south of the Colusa-Leonard.

The Butte & Superior Copper Co. has completed its organization, and has elected A. B. Wolvin, of Duluth, president. Capt. Wolvin is a large shipowner, and has large iron mine interests in Michigan. He is also a director of the United States Steel Co. The Butte & Superior now owns the Blackrock, Niagara, Raymond, Constitution, Jersey Blue, and Four Johns mines, and the fractions known as the Silver Nob, and Duluth. In addition to these it has acquired fractional interests in several other claims, and is negotiating for others. The main working shaft being sunk on the Blackrock has reached a depth of 560 ft., and it will be put to the 800-ft. point before any cross-cutting is done. The company expects to get into the vein at that depth by the first of May, upon which date the stock is to be issued to subscribers.

London.

Retrospect of the Market.—Kaffirs Dull.—Copper Strong.—Cornish Tin Mines.—New Companies.—Scarcity of Labor.—Purchase of Interest in Dues.

The review of mining quotations during the past year reveals, in the case of Kaffirs, the finished work of the noisy demagogs and fussy doctrinaires who have dominated the political situation since the advent of the present Government to power. The "rascally" stockholders who put their money in South Africa have reaped chaff where they thought to gather in the golden grain. The crop has been abundant but it has fallen through their hands. The Rhodesian section has shared a similar fate, with the solitary exception of Tanganyikas, which about held its ground, owing to specially strong inside support. Speculators who turned to West Africans found little consolation, as in that department also influences, although of a different nature, found in climatic conditions and the delay in bringing the gold to market, had an almost equally depressing effect. Westralians have scarcely made a better showing, with the exception of a noteworthy improvement in Kalgurlis of £2⅞. Indian gold mining prices have also been marked by a drooping tendency, the decline in value of the Champion Reef mine in depth having created a feeling of doubt as to the permanence of the Kolar field. Some relief to the prevailing gloom has, however, come from the regions under the Southern Cross. Victorian and one or two other 'deep lead' shares have shown a welcome advance and all the Broken Hill mines have improved in market value with the sole exception of Block 10; while Waihi and Zeehan Montana are in the same favorable category. The most gratifying retrospect of the mining year is that furnished by copper shares, which have risen vigorously, with the solitary exception of Spassky. Rio Tintos have created a record by rising 23 during the twelve months. Cape Coppers are up 3¼, Tharsis 3, Anaconda 2¼, Cerro Mureano 1¼, and Namaqua has had a brilliant year. In American-managed mines, Esperanza, (Mexico), in spite of the continued high returns and the absence of any adverse reports from official sources, has not been able to maintain its value on the market, the price of the stock having fallen to about one-half of the big figure with which it started the year. Dolores, which sold for a short time up to £2¾, has declined on the reported delays in the completion of the mill, and in consequence of the variations in the engineers' statements as to the value of the ore reserves, coupled with the new issue of £66,000

capital. Camp Bird, after a period of enforced inactivity, has resumed milling with a profit at the mine for November of $142,000. Siberia as an attractive field—wide enough in all conscience—for the mining speculator, has enjoyed much energetic and eloquent advocacy during the year, and in a limited sense it has a certain vogue. The high expectations in the cases of recently floated gold mines in that region can hardly be considered as likely to materialize to the extent which would warrant the existing premiums on the amount of stock involved. The record price for tin—£215 in May last—has given an impulse to Cornish mining which it badly needed. Dolcoaths have doubled in price and East Pools have risen from £2¾ to £12¼. In a comprehensive review of the tin industry the Camborne correspondent of *The Financial News* gives the following interesting table:

Period.	Tons black tin.	Value.	Average price per ton.	Average price white tin.
1841- 0	89,120	£4,010,400	£45 0 0	£66 0 0
1851-60	96,572	6,592,639	66 15 6	114 10 0
1861-70	144,462	8,611,467	61 17 6	66 0 0
1871-80	145,112	7,963,489	56 0 0	108 5 3
1881-90	112,510	7,648,106	53 0 0	98 0 0

1906	6,006	630,067	111 0 8	— — —

The same correspondent remarks that those who are unfamiliar with the mining industry expected to see a much larger increase in the quantity of tin sold during 1906; but it is impossible to equip a Cornish mine, however rich, in the time that it takes to open up a new grocery business, hence the absence of the recently formed companies from the list of producers. The increase shown has been made by the old concerns. On the face of it, the increase of 210 tons would seem highly satisfactory; but it must be remembered that 27 ticketings took place in 1906, as against 26 in 1905. The quantities sold, in tons, by the mines in 1906 and 1905 respectively are: Dolcoath, 1,865 and 1,662; Carn Brea and Tincroft, 868 and 807; Grenville, 727 and 835½; Basset, 696 and 752; East Pool and Agar, 617 and 552; West Kitty, 371 and 296; Levant, 225½ and 267½, South Crofty, 169 and 292½; Clitters United, 157½ and 127; Botallack, 58½ and 40; Wheal Kitty, 47½ and 37½; Bunney Mines, 30 and 54¾; Commerce, 24¾ and 6¾.

Among the new companies registered during the year are the following:

	Capital.
Alfred Mines	£ 30,000 In £1 shares
Cornish Consolidated Tin Mines	100,000 " 1 "
Condurrow United Mines	30,000 " 10s. "
Duchy Development Association	20,000 " £1 "
Herberton Tin Syndicate	10,000 " 1 "
Wheal Vor	60,000 " 10s. "
Wheal Geevor	40,000 " £1 "
Cornish Tin Properties	20,000 " 1 "
Wheal Merth	10,000 " 1 "
South Crofty	50,000 " 1 "
Botallack Mines	150,000 " 1 "
Wheal Commerce	50,000 " 1 "
Wheal Kitty and Penhalls United	35,000 " 10s. "

It is reported that the labor problem in Cornwall this year has been the very antithesis of the general experience of this country, the difficulty being where to get the men for the work, and not where to get the work for the men. The number of miners who have returned from foreign fields has been smaller than the mine managers had hoped for, and the extra laborers have been drawn from other sources, including London and the Midlands. The close of the year has witnessed the consummation of negotiations, which had been going on for some time, for the purchase of the Tehidy Estate interest in West Cornish mine 'dues.' The time was, within living memory, when the Bassett family realized an income of £30,000 yearly from this source. Now the more modest sum of £10,000 to £12,000 is mentioned, although it is said that under the existing leases the mines could be required to pay nearly double that amount. The mines affected include the Dolcoath, which produces £200,000 of mineral per annum and is the deepest tin mine in the world. The others are the East Pool & Agar United, Carnbrea & Tincroft, South Crofty, and Basset Mines, as well as the tin streams that contain the tailing from the mines. The announcement of this deal, involving the removal of an ancient landmark, has apparently been too much for the nerves of local stockholders, as a general slump in prices on the Redruth Exchange is reported. The idea of having to make arrangements for 'dues' and leases with a Board of London financiers in place of the 'Lords' Agent, generally a local man, will require some little time to take root. It is said, however, that there are good grounds for believing that the syndicate, which has made this purchase by an outlay of probably some hundreds of thousands of pounds, will treat the present shareholders in the mines liberally; but at the same time the mining experts of the syndicate are so thoroughly conversant with the needs of the industry that they will probably be able to arrange for an increased and more economical output from the mines, which will enable the shareholders to pay full dues and at the same time to receive highly satisfactory dividends. As to the outlook for the new 'Lords,' it must depend on the energy and success of the developments in the old-established mines, as well as on the re-opening of old ones and the taking up of new mining 'setts' by the continuous introduction of capital into the county. In these operations the financiers in question will in all probability have a direct contributory interest from which the old 'Lords' held themselves aloof.

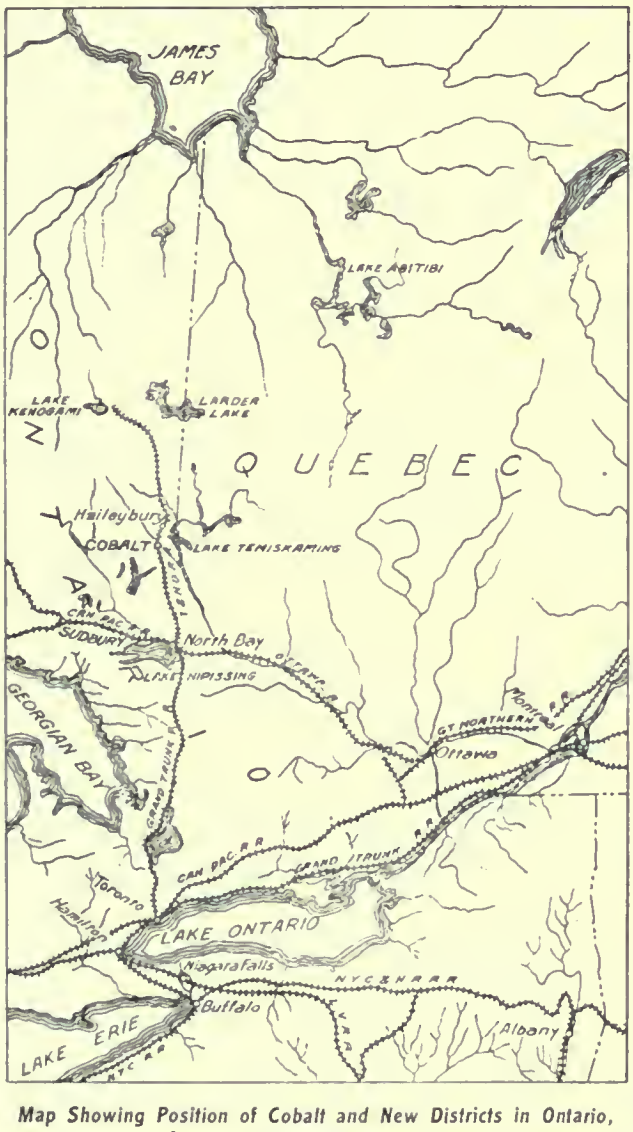
Toronto, Canada.

Canadian Mineral Output.—Mr. Low's Warning Concerning Cobalt.—Progress on the Yukon.—Railroad Extension.—News From the Cobalt Mines.—Activity at Manitou Lake.—Silver Near Port Arthur.

A summary report of the Canadian Geological Survey for 1906 has just been issued. It notes the great progress made in the mining industry during the year, and states while figures are not yet available, they will undoubtedly show a large increase over the output of 1905, which was close upon $70,000,000. Higher prices have helped to increase the value of the output and to stimulate development. Dealing with Cobalt, the director, Mr. A. P. Low, says that he spent three days in inspecting a number of the most promising mines and claims, and saw enough to pronounce upon the phenomenal richness of the numerous veins. The question of the depth to which silver will be found, however, is one upon which no opinion can or should be given with the data at present available. Granting only a moderate depth, there is ore in sight sufficient to produce millions, and only a portion of the deposits has as yet been uncovered. It might be wise, the report continues, for the investing public to consider the large capitalization and abnormal prices of stock of many of these properties, and the large production required to pay a fair profit. Attention is also called to the limited area covered by silver-bearing veins, and the natural impulse to consider properties situated in the vicinity of bonanza claims as being themselves of great value when the reverse is often the case. The reported discovery by Mr. Dowling of a large coal field, extending northward from Saskatchewan past the Brazeau river in proximity to the Grand Trunk Pacific Railway route, is officially confirmed.

Another report dealing mainly with the mining indus-

try recently presented to the Canadian Parliament, is that of W. B. McInnes, late commissioner to the Yukon territory, on the mining and general conditions of the territory. The report deals with the passing away of the more primitive methods of working, which have been largely discontinued during the past summer in favor of operations by large hydraulic plants and dredges. The old process of prospecting by shaft-sinking has been extensively superseded by steam-driven drills. Many of the owners of claims on the older creeks and hills suspended work by the more primitive methods, to await the installation of dredges or a large supply of water. The transition going on accounts for a temporary reduction in the gold output. On the Bonanza, Eldorado, and Hunker creeks, and their tributaries, lying north and west of the Indian river divide, the transition is almost complete,



Map Showing Position of Cobalt and New Districts in Ontario, Canada.

but placer methods, aided by some mechanical contrivances, still obtain on the Indian river side, including Dominion, Gold Run, Eureka, Sulphur, and Quartz creeks.

The Temiskaming & Northern Ontario railway commission has authorized inspections preliminary to surveys for branch lines to the Larder Lake district, and to Portage Bay, the western extension of the Cobalt area. The Larder Lake branch will run from Englehart and will be from 12 to 16 miles long. The Portage Bay branch will be run either from Cobalt or Gillies station and will be five or six miles long.

The Provincial Bureau of Mines has received a fine specimen of ore from the Jacobs mine, Cobalt. It is of dyscrasite, a combination of silver and antimony, and weighs about 10 lb.——Charles A. O'Connell, manager of the Green-Meehan mine, reports that the extraction of ore from No. 1 vein has been going on steadily since Oct. 24. There are two separate shoots in this vein. The south shoot is yielding high-grade ore for a length of 67 ft., the average width being seven inches. The ore of the north shoot, also high-grade, is 5½ in. wide, and is being worked for a length of 45 ft. All the ore is got out by the underhand stope or open-cut system.——A nugget of silver from a recent rich strike at the Temiskaming mine is on view in Toronto. It assays 16,038 oz. per ton, or 50% silver. It was taken from the 70-ft. level of a shaft that is being sunk on the vein. The vein is eight inches wide at this point. The Trethewey mine has now five cars of ore at the Ledoux smelter in New Jersey, F. C. Loring, consulting engineer, is assisting in the sampling and returns are eagerly awaited.——Work on the Big Pete mine, recently acquired by the Cobalt Central Mines Co., is being pushed under the direction of J. M. Elmer, who gained his experience in the Klondike. Ore from a depth of 40 ft. assayed 4,816 oz. silver per ton. An assay from the lower levels showed 1,100 oz. per ton.——The Gamey property north of the Buffalo and west of the Coniagas is to be actively developed. A 60-h.p. boiler and a four-drill compressor are to be installed and about 40 men employed. At the 50-ft. level driving will be done both ways, and the shaft continued. When the shaft is down 100 ft. a cross-cut will be run. Capt. Terrill is mine superintendent, and Albert C. Houghton, consulting engineer.——The Temiskaming & Northern Ontario railway commission has made arrangement for the issue of returns of shipments of Cobalt ores weekly, instead of monthly as at present.

There is a demand for gold-mining properties in the Manitou Lake area, northwestern Ontario. Development operations are being vigorously carried forward by R. B. Nickerson, the superintendent of the Laurentian mine, ore extraction being in the meantime partially suspended. At the Paymaster mine a cross-cut is being run at the 200-ft. level. The shaft was being put down to the 400-ft. level, but operations were temporarily suspended by flooding and additional pumping power is required before the work can be resumed.——Active production is going on at the West End silver mine in the Port Arthur district under the direction of Capt. Hansen. Frequent shipments of ore are made averaging about $15,000 per car.

Salt Lake, Utah.

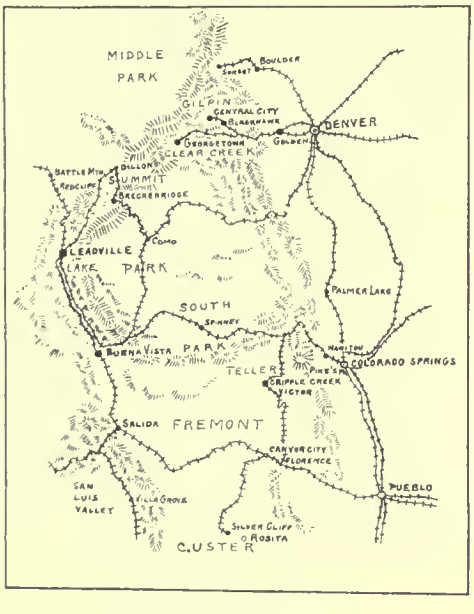
Scarcity of Fuel.— Consolidation at Bingham.— Choosing New Smelter Sites.— Hope of Adjusting Trouble.— The Coal-Land Frauds.— Indictments Found.

On account of the scarcity of fuel, mining operations in Beaver county are much handicapped at the present time. The mill and mine of the Newhouse corporation is closed temporarily; while the Frisco Contact Co. is unable to start its new machinery. The recent heavy snow-fall in that portion of the State has also interfered. —— The management of the Utah mine, at Fish Springs, has kept up the usual shipments, notwithstanding the recent burning of its hoisting plant. The timbers in the shaft were destroyed down to the 500-ft. level. Another shaft is being used for ore extraction. —— The management of the Indian Queen mine has reported the strike of an important body of lead-silver ore.

The Consolidated Mercur has been successful in getting enough fuel for the roasters at the mill, and production is back to about normal. —— The annual meeting of the shareholders of the Ingot Gold Mining Co. is scheduled for this week. It is likely that development work will be resumed. This company's property adjoins the Consolidated Mercur.

Steps have been taken to bring about a consolidation of the Bingham Central and Bingham Standard companies. At the annual meeting of the first named, Samuel Newhouse was named as president; D. C. Jackling, vice-president; W. M. Bradley, secretary; Charles W. Whitley, treasurer. This company has about $26,000 in its treasury, in addition to 106,000 shares of stock.—— It is believed that the project to extend the Mascot adit of the Dalton & Lark mine into the domains of the Ohio Copper Co., since the latter is now controlled by the same interests as the former, will be carried out; that a concentrator will be built near the mouth of the adit. The site of the Bingham Consolidated smelter has not been fully decided, but the impression prevails that it will be on the Josepa ranch, about 50 miles west of Salt Lake.—— W. G. Sharp, president of the United States Smelting, Refining & Mining Co., has been in Utah inspecting several sites for a smelter. This company and the American Smelting & Refining Co. are endeavoring to adjust matters with the farmers and the courts so that they may be permitted to retain their present smelters in operation indefinitely.

Ore shipments from Park City last week amounted to 1,688 tons, the shipping mines being: Daly-Judge, 671; Little Bell, 81; Ontario, 47; Silver King, 496; Daly-West, 393 tons.——The management of the Naildriver mine at Park City has decided to resume work.——The annual meeting of shareholders of the Lower Mammoth Mining Co. resulted in the election of A. C. Ellis, president; John Dern, vice-president, and August Reeves, secretary.——The management of the Colorado and Uncle Sam Consolidated mines reported good developments during the past week.



A Part of Colorado.

A copy of the articles of incorporation of the Markham Gulch Milling Co. has been filed with the Secretary of State. Walter C. Orem is the local manager. The company is now erecting a concentrating mill at Bingham; Boston capital is interested in the enterprise.

The Federal grand jury has brought indictments against C. M. Freed, Walter G. Filer, Don C. Robbins, and E. W. Senior, charging them with being implicated in the southern Utah coal-land frauds. A civil action has been brought against the estate of the late S. B. Milner to regain title to several thousand acres in Iron, Emery, and Carbon counties. The Federal judge, John A. Marshall, in a decree rendered a few days ago, holds that not only does the State have no right to dispose of lands known to contain coal, but, if title passes and it subsequently develops that coal actually underlies the land (although it was not known at the time that such was the case), it is not only voidable, but void. This ruling was made in sustaining demurrers of the defendants in the cases of the United States against the Utah Fuel and Pleasant Valley coal companies, the former to quiet title and the latter to annul certificates of lands by the Interior Department to the State of Utah for fraud, mistake of fact, and error of law in the proceedings ending the certification and because of the land being mineral and not a character intended to be granted by the Government to the State.

Cripple Creek, Colorado.

Successful Leasing.—Strike in the Findley.—Homestake Mills Leased. Another Cyanide Mill.—Change in Smelter Rates.

The north end of the Little Clara claim of the Work Co. is to be operated shortly by the Union Leasing Co. It is proposed to sink a shaft to cut the big ore-shoot being worked by Marsh, Hodges & Co. on the south end of the claim. Eleven air-drills of the buzzer type are being run on the latter lease. Good ventilation of the workings is obtained from a connection with the Callie shaft, and also from a No. 8 blower operated by a 15-h.p. electric motor, which is started up after blasting. Three shifts are running, as the production is being forced owing to the expiratiou of the lease next March, a renewal being uncertain. In the neighborhood of 75 tons per day is being shipped.

A strike of good ore is reported to have been made on the Findley mine on Bull hill. At a depth of 850 ft. on the tenth level a new vein has been encountered and from the assay-returns the ore should ship between two and three ounces. The Findley ore is to be treated at the Portland mill at Colorado City until such time as the Golden Cycle is in operation. This will be the first custom ore the Portland mill will have treated.——A five-year lease has recently been granted to the Phœnix Leasing Co. by A. W. Grant, receiver of the Cripple Creek Homestake Mining & Milling Co., on the Ironclad, Annex, and Pard claims, and the larger of the two Homestake mills. Mining operations will be started at once. It is expected that the mill will be overhauled and put in shape for the hauling of ore by March. The royalties range from 5 to 20%. About 12 months ago a similar lease was granted on the Magna Charta and Quartzite claims and the smaller mill, to the Ironclad Leasing Co. This mill has a capacity of 150 tons per day and has been operated very successfully during the last year.

It is stated that the big building of La Bella Electric Light & Power Co. at Goldfield will be converted into a cyanide mill. The engines and boilers are now being removed. The solid construction of the building, as well as its situation, will admirably fit it for the above purpose.——The Western Investment Co. has struck some good ore at a depth of 450 ft. on Work No. 4 adjacent to the Doctor-Jack Pot on Raven hill. The vein is 18 in. wide and some very high assays have been obtained; the ore is said to resemble that of the Mary McKinney.—— The charges of freight and treatment on ores of the district have been changed again by the trust. On and after January 5 the rates in force are one dollar per ton less than the old open rates, so that the camp now benefits only to the amount of about a dollar per ton over last year's open rates.

Sinking has been resumed in the Ophir shaft on Raven hill, from 700 to 800 ft.——The Victor, one of the earliest profitable mines in the district, is still productive. Lessees are getting good ore at 300 ft. There are large bodies of low-grade stuff in the old workings that are likely to be worked before long.

Mining Summary.

ALASKA.

The Silver Bow Basin railroad, promoted by the Alaska-Perseverance Mining Co., is to be built by the company, and not by contractors. The Juneau terminus will be at the city wharf. The road will be operated by electricity, narrow-gauge, with 35-lb. rails, and low rates are promised from Basin.——The Reynolds-Alaska Development Co. will install a complete electrical equipment on La Touche-Iron Mtn. mine on Prince William sound. The present equipment consists of a Pelton water wheel, two 50-kw. generators, an electric hoist and pump, and four Temple pneumatic electric drills.——Andrew Mitchell and George Francis have discovered a good quartz lode near McGinniss creek, about 15 miles from Juneau.——There is much activity on Hastings creek. Belleview brothers are working five men between Hastings and Saunders creeks, and many others are operating here and in Gross gulch.——The Conrad mines near Conrad City, in the Windy Arm country, have resumed work, a force of men being employed on the Venus, Vault, Montana, and Big Thing group of quartz claims.

The Gold Commissioner's department at Dawson has just laid down two important rules relative to the privilege extended under section 21 of the Yukon placer mining act recently put in force. One rule is that any one using two powers of attorney, as provided in the code, will not be permitted to record under the regulations, unless outfitted for an expedition of at least three months. The second rule is that no man, staking with powers of attorney, will be allowed the discovery claim unless there is gold discovered on the claim. When a man stakes a claim alone, he does not have to find gold. In respect to staking when there is no power of attorney held, the code simply says that a man locating the first claim on any stream, bench, or bar, may locate 1,500 ft. When staking with the power of attorney, a man is allowed to locate on any stream on which he makes a discovery.

ARIZONA.

COCHISE COUNTY.

The Arizona & Michigan Development Co., at Johnson, is still sinking its double-compartment shaft. The annual meeting of the stockholders of the company was recently held at Benson.

GRAHAM COUNTY.

George Dudley, the manager of the Standard mine at Metcalf, is working a full crew of men since the re-opening of the Coronado railroad. The tunnel is being driven at the rate of two feet per day to cut the Copper Centre vein.

MARICOPA COUNTY.

The Relief mine, northwest of Phoenix, is running its mill in 12-hour shifts, as the water supply is too small for a continuous run. Development work is at present confined to the 300-ft. level.

MOHAVE COUNTY.

The Lew-Claire Mining Co. is prospecting with a diamond-drill on its property on Bill Williams Fork. The drill cuts a 6-in. hole and takes out a 4-in. core. Lewis Dewitt is the superintendent.—— Brownsville is a new mining camp in the eastern part of Mohave county. The ore is copper and gold, and the Iowa Development Co. is working a force of 75 men.—— The Big Sandy Co. is operating four miles below Signal. A shaft is being sunk on the Suncloud claim.—— The Standard Co. has reached a depth of 300 ft. on its property southwest of Yucca, at the lower end of the Chemehuevis Mtn. The principal stockholders are Chicago people.—— A $60,000 bar of bullion was shipped from the Goldroad mill to the San Francisco mint, the result of the clean-up after a 15-day run.—— J. R. Garnier, of Los Angeles, has made the final payment on claims in the Cerbat region. Work has started on the St. Louis property under Lew Stirzel, the superintendent.—— The vein in the Banner mine, at Stockton Hill, has widened to four feet. The adit is in 1,800 ft. on the vein.

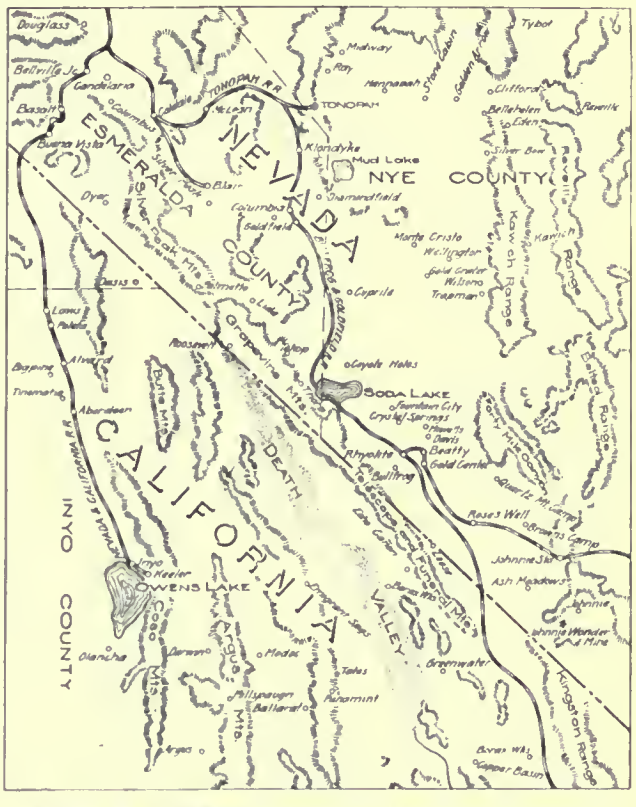
PINAL COUNTY.

The National Mining Co. has under bond the Bryan group of claims, near Kelvin, and the second payment on the purchase price was recently paid to J. K. McCarthy, of Kelvin, and Mrs. Alfred Kinney, of Globe.

CALIFORNIA.

AMADOR COUNTY.

The repairs in the shaft of the Zeila have been completed and the mill started. The chlorination works have been running continuously, as a large stock of concentrate had accumulated before the shut-down.——The Bunker Hill mill treated 2,646 tons of ore in 27 days during December, yielding $14,879 in gold bullion, and 42 tons of sulphurets worth $3,265, making a total of $18,144 for the month. The average yield per ton was nearly $7, and the net earnings $11,500. With the exception of the Argonaut, this is the heaviest



Map of the New Mining Districts of Nevada and California.

producer per stamp in the country.——The mill of the Central Eureka Co. was operated 21 days during December, running at about 60% of its full capacity. During that time it crushed 2,900 tons of ore, which yielded $10,330 in bullion, $2,086 in concentrate, $22 in slime—total, $12,438. The net profit for the month was $2,400. Some trouble between the miners and operators of this property has arisen, due to the poor condition of the hoist-signal apparatus, resulting in the closing of the property.——W. J. McGee has sold part of his interest in the South Eureka to Henry Mallock, who succeeded him as president of the company. The mill is running steadily.

CALAVERAS COUNTY.

The Swiss mine at Railroad Flat is keeping the 10-stamp mill supplied with ore. The upper tunnel is 400 ft. long, and the lower one, at the mill level, is 1,100 ft. long. The entire plant is operated by water-power. The vein is five feet wide at the bottom of the shaft, and averages $6 per ton. A. F. Merell is superintendent.

KERN COUNTY.

The Allie mine in Ivanpah valley has been purchased by Greening & Weinberg from William McFarlane, who located it in 1870.

MONO COUNTY.

The Masonic Mtn. Mining Co. has ordered a mill from San Francisco.——The Standard mine at Bodie has been closed on account of lack of water for power purposes.

NEVADA COUNTY.

The strike of the Grass Valley miners, which has been on since the first of January, has been settled. The miners

agreed to accept the proposition of the State Labor Commissioner, and returned to work on the eight-hour plan, pending the decision of a committee of owners and operators, as to what constitutes an eight-hour day. A unanimous vote was cast in the Union Hall, in favor of accepting the terms, and great rejoicing followed the settlement. The outcome of the conference between the representatives of the miners and operators was the adoption of the following schedule: Start work at 7 A. M., drop tools at 12, pick up tools at 12:30 and drop tools 3:30, the men to be hoisted as expeditiously as possible; night shift on same number of hours, as arranged by the superintendent. This schedule holds until 30 days' written notice of change is given by either side, which will assure ample time for the consideration of whatever issues may arise.——The Alleghany company will start their hydraulic mine at Balsam Flat, on the McNulty claim, as soon as the weather moderates and more water is available. The new pipe-line is finished and the monitor in place.

SHASTA COUNTY.

(Special Correspondence).—In spite of trying weather conditions, considerable activity in railroad construction continues. The Mammoth Copper Mining Co. is conspicuous for its several new undertakings. Eighty men are grading the railroad to connect the Quartz Hill mine with the Southern Pacific. The supply of silicious ores to furnish flux for the recently developed orebody of the Mammoth mine is apparently causing some anxiety, and this company is bonding several properties on the west side of the Sacramento. A contract has been let to haul 50 tons of ore per day from the Rattle Snake mine, situated five miles west of Redding, and the Bowery Belle mine, two miles west of Keswick, is being examined by them.——In the French Gulch district, rich ore has been found in the Washington and Gladstone mines. The latter is now beyond doubt one of the most important producers in this country, though it was sold a few years ago for the value of old machinery on the claim.——Near Centerville several promising prospects are being developed. At the Yankee John mine, a hoist is being installed and the shaft will be enlarged and sunk further. This is a district which has not received the attention which it deserves, because it is a low undulating country, and vein mining has been handicapped by the necessity of sinking shafts and handling considerable quantities of water.——A compressor has been put in at the Little Nellie mine at Iron Mountain. This property is owned by a Pittsburg company.——The Northern California Power Co., which supplies motive power to all the principal mines and smelters in the county, is making preparations to install a 12,000-h.p. electric plant at Battle creek, about 30 miles southeast of Redding. This will be the third large generating station belonging to this company. The Battle creek dam will take nearly a year to build and this work will give employment to over 200 men.

Redding, Jan. 22.

The Mammoth Copper Co. has voluntarily increased the wages of all its employees. About 700 men are affected. The increase will average about 8%, and it is stated by the company that it is the high price of copper that makes the raise possible, and that the increased scale will be in effect until the New York price of electrolytic copper drops below 18 cents per pound. An eight-hour day has been in force at the mine for some time. Fred Lyon is manager of the property, and A. S. Haskell is assistant manager.

SIERRA COUNTY.

The repairs on the 25-stamp mill of the Empire Co. at Gold Valley have been finished, and the entire plant is in good condition for a long run.

The Soda Springs quartz properties have been bonded by E. A. Work and Wm. Penman to Tonopah parties. Five claims are included, and a tunnel is to be driven to the vein.

SISKIYOU COUNTY.

A force of men is at work in the Blue Ledge copper mines in the Elliott and Joe creek sections, near the Oregon line. The new town of Hutton is a lively little camp, situated on Joe creek. The headwaters of Beaver creek are being prospected for copper. Work will soon start on Klamath and Scott river placer claims. All of the placer work is abandoned during the cold weather, and all the stamp-mills are closed down.

Work has been resumed at the Hardscrabble mine, and the Helena mine near Callahan will soon start operations. ——The Whiting Hill mine at Scott Bar will start work with L. E. Hicks in charge.

COLORADO.

The big Camp Bird mill is now running nicely and the Silver Lake mill is nearing completion. The latter will have a daily capacity of 450 tons. The non-operation of these two big mills made a large hole in the 1906 production of the southwestern part of the State.

The famous old Cashen copper mine in Paradox valley, about 12 miles east of La Sal mountains, and close to the Colorado-Utah line, has been sold to the Exploitation Co., of America. Edwin N. Hawkins, of Denver, has been appointed consulting engineer, and active development will be undertaken at once.

GILPIN COUNTY.

The Federal mine, in Russell gulch, adjoining the Old Town on the west, has been leased and bonded for $22,500 by Eastern parties, represented on the ground by W. E. Campbell. The shaft is down 400 ft.——The Bald Mtn. Co., owning a group of claims in Gilpin and Clear Creek counties, is composed of Illinois and Colorado people. L. D. Bloom is the manager. The shaft is down 150 ft. and tunnels are started.——At the Pittsburg mine of the Cashier Co. in the Russell district, work is being done on the sixth and seventh levels, and a cross-cut is being driven from the 300 level toward the Meeker shaft. The shaft is down 720 ft., and 20 men are employed under William Auger, the superintendent.——The main shaft at the Saratoga mine is down 1,000 ft., and is being pumped out, the water now standing below the 800 level.——The Faraday Co., in which Omaha people are interested, is asking for bids for sinking its Argo shaft, situated east of the Alva Adams mine in the Russell district. The shaft is down 160 ft. and the bids are for 100 ft. more. ——About 20 men are at work at the East Notaway mine, operated by the Town Topics Co. Ore is shipped regularly, and milling ore is going to the custom mills. Tom G. Martin is superintendent.——The Eureka mine in Prooser gulch is shipping ore steadily. John C. Jenkins is the owner.—— Wettstein & Co. are working the Fagan property, up Prosser gulch, under a lease from the Gurnell Mines Co.

GUNNISON COUNTY.

The Pitkin district contains several active properties. The Raymond tunnel is in over 2,000 ft. and the mill is making concentrates worth $60 per ton. The mill feed is derived from development work, no stoping being done.——The Gold Links tunnel, paralleling the Raymond, is in over 3,000 ft. and the company will have its mill in operation by the first of June.——The most recent strike in the Carter tunnel was a vein 35 ft. wide, carrying streaks of $10 ore, and the tunnel is still progressing toward the volunteer vein. ——The Grand Prize is shipping ore, and the Maid of Athens, Citizen, and Napoleon have all been steady producers.——The Blistered Horn mill near Tin Cup is turning out concentrates from ore derived from development in the long tunnel.——In the Bowerman district, the Abe Lincoln Co. will build a mill in the spring, and the Gold Ridge has been financed by New York parties and will start work.

SAN JUAN COUNTY.

The Edward Ruth Co. has resumed shipments from the Esmeralda mine, which was seriously damaged last year by a snow-slide.——The Bullion King Co. has opened up some good ore, carrying copper, lead, and zinc, in a 15-in. vein.——The Aspen mine, managed by J. O. Campbell, is getting ready for stoping, preparatory to sending ore to the Silver Lake mill, which will soon be completed.——The Detroit and Colorado properties, locally known as the Champion No. 2, is installing new machinery, a 75-h.p. motor having just been put in place, with work on the erection of the new compressor progressing rapidly. During December this company shipped 10 cars of ore to the smelter, and L. L. Haines, the manager, states that shipments at the rate of a car per day will be begun in February.

SUMMIT COUNTY.

(Special Correspondence).—Work is going on in the Jessie property with a full force of men in mine and mill, and a car of concentrates is shipped each week.——The Swastika Co. is a new corporation formed to operate properties in Summit and Park counties and is capitalized for $2,000,000. Elgin Mawhinney and Joseph H. Chandler of Chicago, Andrew W. Gillette of Denver and C. F. Haselton of Breckenridge, are the incorporators.——The Col. Sellers' property in Kokomo, has been sold by Joseph A. Lamping to Horace B. Hawkins for $12,000. This will be worked under the name of the Delaware Gold M. & M. Co.——The Mize Co. has secured possession of the Winifred, Ruth, Marie, Dorothy, and Magnet properties.——The Vidler Tunnel Co. has acquired the Wilcox tunnel and railroad properties. It is proposed to extend the Denver, Lakewood & Golden railroad over Lookout Mtn., and to traverse the Vidler tunnel, thus making connection with Montezuma and Rathbone. The line will then join the Denver & Rio Grande at Dillon.——The Wellington Mines Co. is shipping ore at the rate of 75 tons per day. Peter L. Cummings has been appointed superintendent for the company.——The French Creek Tunnel Co. is to resume work in the cross-cut drainage tunnel in Bald Mtn. Mark G. Stevens is manager.

Breckenridge, Jan. 17.

IDAHO.

IDAHO COUNTY.

(Special Correspondence).—Idaho county is active. The Goodenough group of claims on Bear creek in the Marshall lake district is the scene of excitement. Rich ore is being brought to the surface. One chunk weighing 75 lb. is shot through with gold, and is estimated to yield $2,000. Nothing like it has ever been known in Idaho county, and Grangeville mining men are starting for the district.——Wesley Everett, manager of the Leslie mine, has just returned from a visit to the Silver Criss mine on the summit at Lookout, near the Montana-Idaho divide. He made an inspection of the workings of the Silver Criss, the mine showing a vein 15 ft. wide. The vein was cut at a depth of 75 ft. from the surface and 200 ft. within the tunnel. This vein will intersect the north and south vein, which was opened by a shaft 150 ft. above. It was from this upper tunnel that some of the best grade ore in the district was taken last year.——R. B. Painter, of the Marshall Lake district, brings news of a strike of gold-bearing quartz in the Lake View claim, recently acquired by Mr. Painter, C. G. Kahn, Frank Baker, and John Morgan, of Spokane. A seven-foot orebody carrying gold was cut by the shaft at the 65-ft. level. The property has been shut down for the winter, but the owners will start work next spring. A copper strike is reported by James Taylor, part owner of the Bullion mine, who announces that six feet of concentrating ore has been encountered in the lower tunnel.——C. W. Hadley, one of the principal owners of the Washington Meteor mine, says that rich ore has been found in the five-mile tunnel, the lode being from 12 to 16 ft. wide. The company is installing a 40-stamp mill and it has other heavy machinery.——A 100-ton electro-cyanide plant has been ordered from a Portland firm for installation on the Clearwater group early next summer. This group is on the Clearwater river, about five miles from Elk City. It is owned jointly by George Esh and Mrs. H. Helbern, of Portland.——D. T. Loper and George Conner have sold a three-fourths interest in the Kimberly and Jewel claims, in the Marshall lake district, to E. B. Miller, of Los Angeles, for $25,000. Mr. Loper retains a fourth interest.——M. De Keyser, mining expert of Belgium, is in the Elk City district looking over the field with a view to establishing a custom mill. He represents French and English capitalists.

Spokane, Jan. 20.

LATAH COUNTY.

(Special Correspondence).—The Gold Bug copper mine on Jerome creek will be the first shipper in what is known as the Hoodoo and Gold Hill mining districts. Officers of the company announce that $15,000 worth of machinery has been purchased for immediate installation. Shipment of ore will begin as soon as the spur of the Washington, Idaho & Montana railway is completed up Jerome creek. The mine is probably the best developed property in the district. The shaft is down to the 300-ft. level, showing values in gold and copper of $60 per ton. Lellis F. Smith, of Colfax, is president of the company.

Spokane, Jan. 20.

SHOSHONE COUNTY.

(Special Correspondence).—Much development work is being done at Murray, on the north side of the Cœur d'Alene mining district, and it is believed that the output of silver and gold will be large this year, as nine mills, with 68 stamps and two galena concentrators, are being overhauled for operation, and a three-stamp mill is working. Other properties with mills are: The Golden Chest mine, Morris Haymon, of New York, president; The Golden Reward, 20 stamps; the King, the Yosemite, Daddy, and Mother Lode, 10 stamps each; the Lyon and the Buckeye, three stamps each. The Lyon mine was operated last winter by Silas Bunch and William Wylie under a lease and they took out $17,000 in three months. The Golden Reward has also produced rich ore, while the Pilot stands at the head of the list of producers. The Cornucopia, Gold Back, the Emma, the Eureka, and the Dew Drop are also promising properties. One pocket in the Emma netted its owners $30,000 eight years ago, but now the property is at a standstill.——The Pilot mine, where John Docktor, Louis Prager, and Frank Frohling made a sensational discovery a few months ago, now has a tunnel of 500 ft. and the paystreak is holding its own. Thirty tons of good ore are ready for shipment. The property was bonded some time ago by a Cœur d'Alene syndicate, headed by the Day brothers, but lapsed after the first payment was made.——The Bear Top concentrator is running. The Black Horse mine is also on a shipping basis. The controlling interest has been bonded for $100,000 to the Federal Co. The mine is a galena proposition and has a developed vein of four feet, some of which is shipping ore. No ore is being mined, however, as the owners are awaiting transportation facilities. The Monarch mill is idle and no ore is mined, all work being confined to driving a tunnel, of which 300 ft. remain to be done.——L. W. Stedman, manager of the Chicago-London and the Paragon properties, announces it is expected to begin shipping soon. The former has a compressor plant. The Cedar Creek prospect has encountered shipping ore in its tunnel of 600 ft., which is being driven by J. H. Jackson and John M. Weyer. With such transportation facilities as will be offered in a year by the Idaho Northern and the Oregon Railroad & Navigation companies the district should develop rapidly. Murray is a camp dating from 1883, when A. J. Pritchard, pioneer gold hunter and pathfinder, panned out the first gold discovered in the district from the bed of the stream bearing his name. That was several years before galena was found in the Cœur d'Alenes.——The International Co. has secured two groups of claims for $35,000. One of the groups consists of four claims and adjoins the Bunker Hill & Sullivan property. These claims have been held and worked for years by pioneer prospectors and it is reported a 12-ft. lode runs through the property. The ore is silver-lead. The other group is across Pine creek. There are five claims, having a wide vein in which galena ore has been encountered. The company making the purchases also has 11 claims near the headwaters of the St. Joe which look promising and which will be developed. These are copper properties. The company is negotiating for four claims in the Pend d'Oreille district. The International will have its head office in Spokane. The capitalization is $2,500,000. A. E. Barnes is president, the other officers being as follows: Eugene Barnes, secretary, and Fred R. Lovell, treasurer.

Spokane, Jan. 20.

MONTANA.

MISSOULA COUNTY.

(Special Correspondence).—The Tarbox mine, situated three miles from Saltese, is opened to a depth of 600 ft., and has been developed by about 1,600 ft. of drifts, cross-cuts, and winzes. The vein dips 60°, being on a contact of quartzite and slate. The width between walls varies from 30 to 50 ft. The ore comprises galena, silver, and iron, in a quartz and quartzite gangue. Assays show values running $25 to

$50 per ton. The boiler capacity is to be increased and pumps installed, preparatory to sinking the main shaft 200 ft. deeper. By driving toward the body of the mountain on the strike of the lode, much greater depth below the surface is to be gained. The installation of a mill before the end of this year is contemplated. Richard Daxon, of Wallace, Idaho, is president of the company and manager of the property.

Missoula, Jan. 19.

NEW MEXICO.

GRANT COUNTY.

(Special Correspondence).—The Tyrone Development Co. has purchased a group of 10 claims about a mile north of the Robinson group, and adjoining the Top mine, for $125,000.——The Robinson mine is owned by W. C. Porterfield and his associates, and some strikes of high-grade copper ore have lately been made in the workings.

The Austin group has an excellent showing, and some rich new discoveries have recently been made in the Lost Bullion Spanish mine. A shaft which was sunk by a prospector in 1875 has a vein from 6 to 8 ft. wide averaging $30 per ton. This shaft is 75 ft. deep and a drift of 50 ft. along the vein shows good values. An old dump has been found

Map of New Mexico.

on another portion of the property and is being sampled by cuts and shafts. In the western part of the workings a new vein of ferruginous quartz has been struck which assays well in gold and silver. The company is considering the erection of a treatment plant of a daily capacity of 500 tons. W. E. Wilson is the president of the company.——An old property in the Chloride Flat district has been purchased by Eastern parties, and is shipping ore which nets $10 per ton. A survey has been made for an extension of the Burro Mtn. railroad from Silver City to Tyrone, and construction work is expected to start soon.

Silver City, Jan. 17.

NEVADA.

ESMERALDA COUNTY.

Many of the leases on the Mohawk have expired, and operations will be continued by the company. New ore-bins are being erected at the Mohawk, Red Top, and Jumbo. The company shaft at the Mohawk is being partly re-timbered to stand the heavy work that will be required of it. The Frances-Mohawk ground is being timbered in places which were weakened by the removal of pillars during the closing hours of the lease.——The Hayes-Monette lease on the Mohawk having expired the hoist is being moved to the Goldfield Columbia. M. J. Monette reports that the greatest production for one day was $60,000, the total production was $4,400,000, and the ore averaged $400 per ton. Most of the output was through No. 1 shaft. No fatalities occurred during the life of the lease and an average of 130 miners was employed for several months. The original lease was 373 by 700 ft., but two-thirds of this area was sold to other lessees.

LINCOLN COUNTY.

(Special Correspondence).—Edw. Carleson reports that he has struck the apex of the ore-shoot in the Wyoming-Searchlight mine in the north cross-cut on the 215-ft. level. —— Recently pay-ore was encountered in the Searchlight-Mammoth on the 100-ft. level. This find is surprising, as the best values are rarely found above water-level. Machinery necessary to sink to the 500-ft. level has been ordered.——To the north of the Wyoming-Searchlight, work on the Golconda has been progressing under the management of W. W. Burt. The shaft has reached the 200-ft. level, and cross-cuts will be run to the vein. In sinking, the shaft ran through 14 ft. of mineralized vein-matter at a depth of 90 ft., and another body, 10 ft. in width assaying $24, at a depth of 125 ft. The hoist installed on this property is in working order, and the shaft will be sunk to the water-level.—— The management of the New York Searchlight Co. has ordered a diamond-drill. The introduction of the drill in Searchlight will mean much to the owners that cannot afford to sink shafts in exploring their properties.—— The good ore recently found on the Stanley Forbes property, east of Searchlight, continues as work progresses. The adit is now in 130 ft. on the vein, and the orebody averages five feet in width. Jos. McArthur is in Los Angeles purchasing machinery for the mine.—— G. W. Huntington is operating the Superior-Nevada and Crescent Searchlight properties. Five feet of ore has been struck on the Superior-Nevada, running $36 per ton, and in the King Solomon tunnel the vein was intersected at 110 ft. A cross-cut showed nearly four feet of good milling ore.—— George Straub has let a contract to sink his 50-ft. shaft to water-level. This property is near the Wyoming-Searchlight, and a well-defined vein can be traced the entire length of the Bank Bell and Crystal claims. The shaft is being sunk on this vein, and the hoist has arrived and is being set up.

Searchlight, Jan. 14.

The Santa Fe extension into Searchlight will open on the first of March. This spur runs from Barnwell, into the camp, a distance of 23 miles.

LYON COUNTY.

Yerington is a growing camp and some excellent copper ore has been developed. The town is situated on the Walker river, 12 miles from Wabuska station, and 35 miles east of the California line. The altitude of the town is 4,300 ft. above sea-level, and the supply of water is good. The Nevada-Douglas ground is being developed, and the Ludwig property has recently changed hands.

NYE COUNTY.

The mines of Tonopah paid nearly $4,000,000 in dividends last year. The largest shipper was the Tonopah Mining Co., which sent out 67,000 tons; the Montana Tonopah, 4,650; Midway, 4,000; and West End, 1,000 tons. The Macnamara, North Star, and Jim Butler shipped 1,600 tons altogether, and miscellaneous shipments, 275 tons. The Tonopah Mining Co. has completed a 100-stamp mill at Millers, 13 miles from Tonopah, and the Midway mill has also been purchased. The shaft of the Belmont has been widened to three compartments and is down 1,100 ft. The Montana Tonopah company is erecting a 40-stamp mill. The Tonopah Extension has found the lode 1,200 ft. west of the shaft, and has developed an orebody 45 ft. wide. When the mills now in course of construction are completed, the output of the Tonopah district will be greatly increased.

STOREY COUNTY.

The Butters plant at Virginia City is being equipped for handling custom ores from various parts of the State. The tramway that will carry the ore from the Virginia and Truckee railroad to the mill in Six Mile cañon, a distance of three miles, is nearing completion. The buckets will hold 100 lb. each and will be 70 ft. apart on the cable.

WHITE PINE COUNTY.

The Cumberland-Ely Copper Co. owns approximately 650 acres of mining land adjacent to and intermingled with the property of the Nevada Consolidated Copper Co. Active development work has been under way for the past year and ore has been proved in a number of its properties. The most important find has been in the Veteran property where, at a depth of about 450 ft., a shaft has gone through 80 ft. of ore, from which a cross-cut has been run 180 ft. and drifts run 70 ft., all in ore that will assay from 3½ to 6% copper, with some gold values. From surface indications and results obtained by the Nevada Consolidated Copper Co., it is expected that this orebody will prove to be at least 1,400 ft. wide. The faces of all cross-cuts and drifts are in ore. The average ore thus far encountered in the Cumberland-Ely properties is similar to the ore of the Nevada Consolidated, but appears from the present development to be of a slightly higher grade. The estimate made by J. Parke Channing of the net cost of copper delivered in New York was 7.03c. per lb., deducting the value of the gold and silver produced.

The company is amply provided with working capital, having available approximately $3,800,000, including the proceeds of 100,000 shares recently offered for subscription to the stockholders and which was underwritten at $12.50 per share. Of this amount, between $2,500,000 and $3,000,000 will be used to pay for a one-half interest in the Steptoe Valley Smelting & Mining Co., the other half-interest to be owned by the Nevada Consolidated Copper Co. The Steptoe Valley Smelting & Mining Co. is now building a concentrating and smelting plant with a daily capacity of 4,000 tons of concentrating ore and 2,000 tons of smelting ore, which will be completed about Jan. 1, 1908. It is expected that this will be increased to a plant of 10,000 tons or more capacity. It will be located at McGill, 14 miles from Ely on the line of the Nevada Northern railroad, where the company has acquired eight square miles of territory and water rights of the entire section, with sufficient water to treat at least 25,000 tons of ore daily. The object of securing this large area is to prevent the possibility of any damage claims arising from the smoke nuisance or the pollution of water, as has been the case with the smelters at Anaconda, Montana, and Bingham, Utah. The Cumberland-Ely Copper Co. also owns a half interest in the Nevada Northern railroad, which road is already in operation from Cobre, Nevada, 140 miles to Ely. The other half interest is owned by the Nevada Consolidated Copper Company.

The officers and directors of the Cumberland-Ely Copper Co. are S. W. Eccles, G. M. Borden, George E. Gunn, William B. Thompson, Frank W. Hills, and Pope Yeatman.

OREGON.

BAKER COUNTY.

The Virtue Mines Development Co. is the name of the company that has effected a consolidation of 16 lode claims and three placers, including the old Virtue mine, with the Collateral, Virginia, and Little Pittsburg groups, making 400 acres of mineral ground situated 10 miles northeast of Baker City. J. K. Roming, president and general manager of the company, states that the Virtue mill is being overhauled and its 20 stamps, plates, and vanners put in order. Chas. P. Loomis is superintendent. The milling machinery and air compressor will be operated by electric motors, deriving their power from the Eagle river plant. The five veins on the property consisted of a fine-textured quartz gangue, carrying free gold and some sulphides, the walls being greenstone.

Articles of incorporation of the Sovereign Consolidated Copper Co. have been filed with the Secretary of State, and the organization was perfected on December 5, with headquarters at Baker City. This company has acquired a large group of copper claims situated on the east side of this county, near Sparta. The development of these properties is of more than usual interest and importance to those interested in mining in eastern Oregon. In the first place, the smelting outlook is brighter, with the prospects of obtaining a large tonnage of ores bearing iron and sulphur for fluxing, and copper, which is essential for the collection of the precious metals.

SOUTH DAKOTA.

PENNINGTON COUNTY.

(Special Correspondence).—In running a drift at the Clara Belle mine near Oreville, at a depth of 265 ft., a vein of tin ore was encountered four feet wide. It was followed 26 ft. Ten pounds of this average ore yielded four ounces of pure tin; 30 lb. of this average ore yielded 10 oz. tin of good quality. The ore also assays $1.50 in gold.

Boise, Jan. 8.

BRITISH COLUMBIA.

A crisis has been reached in the coal situation, and the Canadian Pacific railroad has formally notified the mines and smelters that they will not undertake to handle any more ore until further notice. The immediate result of the announcement was the laying off of the entire force at the Granby Gold Drop mine, and the reducing of the forces at all the other mines of the Boundary that rely upon this road for fuel and ore hauling, including the Dominion Copper, B. C. Copper, and Snowshoe properties. Later, the Granby smelter closed down, and over 350 men are idle. The Le Roi mine also closed down, but later started work again with coke sufficient to run the boilers for ten days.—The new electric hoist for the Centre Star mine, which is being built by Nordberg in Milwaukee, will be shipped about the middle of the month. This will be the largest hoist in the Dominion, being rated at 250 h.p.——The Great Northern will build a spur to the Victoria shaft, and the Canadian Pacific will lay a track to the Victoria head-works in the spring. This shaft will be the main working shaft of the Granby Co. It is down 400 ft.——Shipments for the week ending Jan. 12 were: Centre Star, 1,230; Le Roi, 2,065; Le Roi No. 2, 150 tons, and 680 tons milled. The Trail smelter received 3,735 tons during the week, other mines in the district contributing as follows: Snowshoe, 305 tons; Lorna Doone, Silverton, 85; Lightning Pete, Edgewood, 21; Queen, Salino, 27; Eureka, Slocan, 16; North Star, Kimberley, 61; Kootenay Belle, Slocan, 21, and Last Chance, Slocan, 66 tons.—— The Northport smelter is run by ore from Le Roi mine, receipts from that property amounting to 875 tons for the week.

To the north of the Boundary district there is some activity in copper properties. In the Similkameen valley is the Nickel Plate mine at Hedley, and the properties on Copper mountain, near Princeton. Still farther north, in the valley of the Tulameen, the Cousin Jack mine is being worked.—— The Nicola mining district lies 40 miles north of Copper mountain. Here are found copper, iron, and coal. The Asheroft and Highland Valley districts lie 40 miles north of Nicola lake. Here work is progressing at the Ivanhoe, Glossy, Transvaal, Highland, Keystone, Albatross, Ball, and Tamarack group of claims. Good veins have been exposed, and the district is a promising one for a future production of copper, transportation facilities being as yet entirely lacking.

The Dominion Copper Co. operates the Sunset, C. O. D., and Crown Silver mines at Greenwood, the Brooklyn, Stemwinder, Rawhide, and Idaho in the Phoenix district, and the Athelston farther north. The principal producers are the Rawhide, Brooklyn, Sunset, and Idaho. The ores run from 2½ to 3% sulphur, and they contain from 1.2 to 1.3% copper. They also carry small values in gold and silver. Shipments to the company's smelter at Boundary Falls, from all the mines named, amount to 650 tons per day, the product being a 45% matte, which is sent to the converters of the B. C. Copper Co. at Greenwood. The present capacity of the plant is being doubled by the addition of a 255 by 48 in. matting furnace, which will doubtless be blown in by March 15. A change from steam to electric power is being made, the electric power to come from the plant of the Cascade Power Co. at Grand Forks. The change, it is stated, will effect a great saving in the cost of power. Samuel Newhouse is managing director of the Dominion company, ex-Senator Warner Miller, of New York, being president. On the operating staff are T. R. Drummond, the manager; M. M. Johnson, the consulting engineer, W. C. Thomas, the smelter manager, and E. E. Gardinier, the mine superintendent.

Personal.

R. G. BROWN is in Siberia.

C. W. KEMPTON has arrived in Chile.

H. R. PLATE is inspecting mines at Ward, Nevada.

C. F. MOORE, of Salt Lake, is at Pachuca, Mexico.

FRANK MERRICKS left England for Peru on January 16.

JOHN B. FARISH has returned from Chihuahua to Denver.

PERCY E. BARBOUR is inspecting mines at Goldfield, Nevada.

GEORGE J. BANCROFT has returned to Denver from Nevada.

G. H. ATHERTON, of Cripple Creek, is on a visit to San Francisco.

DONALD B. GILLIES is visiting San Francisco from Tonopah, Nevada.

F. B. CLOSE is general manager for the Helvetia Copper Co., in Arizona.

S. E. BRETHERTON is visiting San Francisco from Redding, California.

C. R. FARQUHARSON has left London to proceed to the Federated Malay States.

R. DE SALLIER, chief assistant with R. M. Atwater & Co., is at Denver on business.

NORVAL WELSH is superintendent of the Santa Brigida mine near Chihuahua, Mexico.

T. R. MILLER, of Denver, is in the Black Hills of South Dakota on professional business.

E. A. H. TAYS is on his way to examine the Anderson lake mines in British Columbia.

S. A. WORCESTER, of Victor, Colo., is engaged in professional work at Bellevue, Idaho.

H. T. WILLIS has left the Dolores mine, Mexico, and is temporarily at his home in Illinois.

HOWELL HINDS is president of the Old Hundred Mining Co., operating at Silverton, Colorado.

F. T. BYRDE is on his way from London to Liberia, where he expects to remain 18 months.

HARRY A. LEE has been appointed consulting engineer to the Unity Mines Co., at Alta, Utah.

C. B. WINGATE has returned to San Francisco from an arduous trip to the mines of Death Valley.

JAMES ARKELL is general manager for the Santa Rita Mining Co., at Sombrerete, Zacatecas, Mexico.

F. X. MOONEY is superintendent of the smelter department for the Metals Extraction & Refining Co., Chicago.

FLOYD K. THOMPSON is the new manager of the Sierra Plata Mining Co., operating Los Muertos mine at Parral, Mexico.

CHARLES PFEIHL, of Denver, has just returned home after making some examinations of zinc mines in southwestern Missouri.

T. ELLIOTT SMITH has been appointed manager of the Santo Domingo Mining Co., at Etzatlan, Jalisco, to succeed W. M. MATHEWS, resigned.

PETER L. CUMMINGS, of Breckenridge, Colo., has been appointed superintendent of the Wellington Mines Co., operating in the Breckenridge district.

W. G. SHARP, president of the United States Smelting, Refining & Mining Co., is making an inspection of the Mammoth mine in Shasta county, California.

W. E. WILSON, of Boulder, Colo., has been elected president of the Lost Bullion Spanish Mines Co., of Silver City, New Mexico, and is now on a visit of inspection to the property.

THOS. M. HAMILTON, former superintendent of the Escuadra mine at Taviche, Mexico, is now general superintendent of the mining properties of the Braden Copper Co., at Graneras, Chile.

W. H. YEANDLE, JR., has resigned the management of the Cia. Minera El Banco y Anexas, Oaxaca, to accept the position of superintendent of the San Luis Mining Co., at Gabriel, Durango, Mexico.

T. F. TREWEEK has resigned his position with the Lustre Mining Co., at Santa Maria del Oro, Durango, to accept the position of chemist with the Tecolotes mines at Santa Barbara, in the same State of Mexico.

GEORGE E. HOWARD, formerly of the American Smelting & Refining Co., at El Paso, Texas, is the new manager of the Sahuayacan Mining Co. at Ocampo, Chihuahua. He succeeds JOHN C. TREADWELL, resigned.

ARTHUR WORSDELL will have charge of the cyanide plant and GEORGE S. EMBURG, of the concentrator, at the mine of the Coast Line Copper Co. at Querobabi, in Sonora, Mexico. JOHN HENDERSON, of Pasadena, Cal., is general manager.

Obituary.

WINFIELD SCOTT KEYES died in San Francisco on December 27, at the age of 67. He was graduated from Yale in 1860, and then studied for three years at Freiberg. After gaining some experience in California, he became superintendent of mines at Eureka, Nevada, where he and Arents invented the automatic tap for lead furnaces. Subsequently, he went to Leadville and was manager of the Crysolite mine at the time when it was prominent on the Stock Exchange of New York. At a still later period he was frequently an expert witness in mining litigation. During the last few years he engaged in mining in Mexico, and in wine culture in Napa county, California, receiving a gold medal for his wines at Paris in 1900. He lived at the Pacific-Union Club, and had a large circle of acquaintances.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

MINERS are wanted at Cobalt, Ontario; they can get $2.50 per day and their board.

IT IS likely that there will be a rush in the spring to the Larder Lake district, north of Cobalt, in Ontario.

STATISTICS show that the occupation of a coal miner in England is ten times less dangerous to life than the occupation of a sailor.

FOR sinking oil-wells in Japan, reflected daylight is used. A piece of yellowish translucent oil-paper is suspended over the well at an angle of 45° and throws light down the pit. The wells are dug to a depth of 600 or 800 feet.

GREASE is so bad for amalgamation that sperm or paraffin candles are used at many gold mines, as they are less objectionable than those made of tallow. The latter do not stand so strong a draft, nor drops of water, as well as the former, but give less smoke, spoil less air, and do not gutter so much.

PROF. LANGLEY has shown that the Earth receives energy from the Sun at the rate of 25 h.p. per square metre, or the latter must radiate from its surface more than 100,000 h.p. per square metre. If the sun were solid coal, it could not maintain this supply by combustion for 3,000 years.

IN driving the Bell tunnel at the New Idria quicksilver mine (California), after an explosion of some inflammable gas, the tunnel was lighted by the reflection of the sun's rays. A mirror was kept at the mouth of the drift at the proper angle to effect this, and as long as the tunnel was driven straight it answered perfectly.

ACETYLENE LAMPS should be used by all shift-bosses and foremen who have the inspection of high backs or of much timbering. The newer forms can be turned in any direction, and can even be upset, without danger of extinction, while the increased brilliancy of illumination will soon pay for the first cost, by the rapidity and efficiency with which the inspection may be accomplished.

THE Australian miner uses a candlestick somewhat similar to the ordinary American holder. It is known as a 'spider,' and consists of a wire about one-sixteenth of an inch thick, hoisted into a spiral that holds the candle. The upper end is prolonged vertically upward, terminating with a hook for hanging, while the lower end is attached to an iron rod for thrusting into timbers or crevises.

VAN HISE, in his paper on ore deposition, refers to the zone of 'rock flowage,' at a depth where the weight of the superincumbent mass is greater than the ultimate strength of the rock. This is exemplified in common life in many solids, especially metals, which will spread laterally, or flow, if subjected to sufficient pressure. And the phenomenon is made use of in the arts of wire-drawing, tube-making, and in coinage.

ALL the Lake Superior mines make use of the tin coffee-pot-shaped lamp burning paraffin wax. The wax, which is called 'moonshine,' is kept melted by the conduction of two long copper nails passing through the wick from the flame to the body of the lamp. About every two hours the wax is replenished from the box, which each miner brings down with him. This is quickly accomplished. They are clean and much cheaper than candles, give a good light, but are rather smoky and hot when carried on the hat. The attitude of the miner toward their use is determined by custom and prejudice rather than intrinsic merit.

IF air at atmospheric pressure and 60° F. could be compressed to 100 lb. gauge-pressure and all the heat due to the work of compression taken away as fast as generated, so that the temperature during compression would remain constant, the mean effective pressure during one stroke of the air piston would be 30.2 lb. If, on the other extreme, none of the heat due to the work of compression is taken away, the mean effective pressure during the stroke will be 41.6 lb. and the terminal temperature will reach 485° F. As the power required for compression is directly proportional to the mean effective pressure, it will be seen that the additional power required in the latter case is 37½% of that in the former. In practice neither extreme can be reached, for it is impossible to completely cool the air during compression, and, on the other hand, some of the heat of compression will be radiated; but the lower extreme is the ideal, and the nearer it can be approached the more economical will be the work done.

REPLYING to the question regarding the use of oil to be injected, together with air, through the tuyeres into the blast-furnace, an experienced metallurgist states: "It would appear that if its combustion takes place as it enters the glowing coals, then, while heat would be evolved as result of such combustion, at the same time an exhausted atmosphere or mixture of fouled gases would be present quite unsuited to burning the coke. I have taken air, heated by the burning of oil, and have blown it through the tuyeres only to see it extinguish, instead of burning, the solid fuel, all because of the contained exhausted CO_2 gas there present. It may be exemplified by those cases where the foul air of an unventilated mine will hardly support the combustion of a candle. For intense combustion of solid fuel, the air, while it may be hot, must be fresh, and, even in such cases and with the large furnaces, active combustion ends by the time the air has penetrated the glowing fuel about three feet. After that, as the CO_2 becomes reduced to carbon monoxide, the reaction is endothermic."

THE work performed by an air compressor is that of increasing the pressure by reducing its volume or compressing it into smaller space. Usually the initial pressure is the 'atmospheric pressure' at the compressor, while the terminal pressure is fixed by the requirements of each case, and may be anywhere from 10 to 30 lb. (gauge pressure) per square inch, as in blowing engine practice, up to 80 to 100 lb. per sq. in. for rock-drills, pneumatic tools, etc., and up to 1,500 to 2,000 lb. per sq. in., or even higher, for special purposes. Compressors that work against pressures under 30 lb. gauge are usually called blowing-engines. Atmospheric pressure (or zero gauge pressure) equals 14.7 lb. absolute pressure per square inch at sea-level (equivalent to 30-in. barometer), and becomes less as the altitude above sea-level increases, the decrease being approximately one-half pound, or one inch in mercury column, for each 1,000 ft. increase in altitude. As the work of compression depends upon the initial and terminal absolute pressures (absolute pressure being equivalent to gauge pressure plus atmospheric pressure), the altitude at which the compressor is to work is of great importance and should always be taken into consideration.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Blast-Furnace vs. Reverberatory.

The Editor:

Sir—Answering the twelve questions brought forward by Mr. J. W. Neill, I beg to offer the following:

1. *On what should the choice of furnace type be principally based? Choice of ore, fuel, fluxes, building materials?*

The choice of furnace should be based on the physical as well as the chemical structure of the ore. For instance, a heavy pyrite ore may be so fine that it would be folly to treat it in the blast-furnace, even though it carried an excess of Fe and S, as the flue-dust made would be so great that it would have to be briquetted before it could be retreated in the blast-furnace. The most sensible method would be to screen the ore first, and smelt the coarse ore in blast-furnaces, then roast the fine in mechanical roasters and smelt the calcine and flue-dust in reverberatory furnaces. This would require both types of furnaces. It has been my experience that a mixed plant has more advantages than a plant with only one type of furnace. However, there are several single-type plants operating very successfully in the West. For a variety of custom ores it will generally require both types, but several different grades of ores from the company's own mines may be treated economically in the one type only, owing to the local conditions, namely, cheap coal for reverberatory furnaces and cheap coke and flux for blast-furnaces.

The reverberatory would seem to have an advantage in many localities over the blast-furnace, as coal, oil, and wood can be used. However, the first is preferable where coke is the chief fuel on the blast-furnace, unless the natural fuel (FeS_2) in the ore itself can be used pyritically.

Lime is a constant drain on the metal, especially in the blast-furnace, as the percentage will usually range from 15 to 25% in the slag, and if a barren iron ore is used it will figure against the recoveries in the same proportion. In the blast-furnace, in Utah and Montana practice, the amount of slag produced will approximate the ore charged, the volatile constituents and matte will almost equal the flux used, while in the reverberatory the slag produced will not be over 60% of the original ore. So, if we assume 2% Cu ore smelted either way, with 0.25% Cu in the slag, the recovery would be 87% in the blast, and 91% in the reverberatory. However, it is usually cheaper to furnish the fluxes for fast driving than to do without them and run slow with a much higher loss per ton of slag made. If one has converter slag, it will usually eliminate the iron ore and furnish its own values. It should always carry a high percentage of excess Fe, and if the converter linings are properly dried, this is easily done.

Steel buildings should be used by all means for the smelting and roasting-furnaces, also the crane and converter building, brick for the engine-room and power buildings, because it is warm in winter, and can be made cool in the summer. The shops, ore-bins, and sampling-mill, can be built of wood, and should be placed far enough away from the main buildings for safety. Steel water-jackets are best for copper blast-furnaces, and the brick top should go through the roof, so that the downtake cannot radiate heat on the workmen. I always use the best silica and clay brick in the market for reverberatory-furnace work. They are the cheapest in the long run. A modern furnace will run about one year before repairs begin. Buck-stays cannot be made too strong. I would not use any material for the bottom with less than 90% SiO_2, unless it is high in Al_2O_3.

2. *What are the comparative costs per ton of daily capacity of each type of furnace?* (In the case of the reverberatory, this cost should include the expense of the necessary roasting plant.)

While I think the roasting cost should be charged to the reverberatory cost of smelting, still, the reverberatory should get credit for treating the flue-dust made by the blast-furnace and converters, by charging back the reverberatory cost per ton according to the amount of dust recovered from them. For example: Supposing both furnaces were running on equal tonnages of say 150 tons each, which was the case at Butte, and the reverberatory furnace was smelting 15 tons, or 10% of the charge flue-dust made by the blast-furnace. To give each type credit for actual smelting, we would proceed thus:

Blast-furnace	150 tons ore	at $3.85	per ton
Blast flue-dust made and smelted in the reverberatory	15 "	" 0.36	"
Total cost		$4.21	"
Reverberatory furnace	135 "	calcine	
Blast flue-dust	15 "		
Total charge	150 tons	at $3.65	"
Interest on 200 tons matte		0.05	
Charge roasting cost at		0.50	"
		$4.20	

I have made no interest charge on the blast-furnace, as it would be too small to consider. There is still another credit due the reverberatory, which is not shown, and that is the horse-power developed by the boilers attached. This should easily offset the roasting cost. I do not think wet concentration or converting should be charged to either type of smelting, as the product is treated in both. The coarse concentrate, slime, and some fine concentrate are treated in blast-furnaces, while all the fine should go to the roasters, and then smelted in the reverberatory furnaces.

3. *What is the comparative space requirement for an equal tonnage?*

Just figuring on the buildings to properly house each type of furnace and allow proper working room, I would say 33.3% less space is required for a blast-furnace of equal tonnage than for a reverberatory with boilers attached.

4. *What is the comparative cost of mechanical equipment for equal tonnages?*

I understand this question to mean in the case of blast-furnaces, the blowers, steam-engines, motors (electrical), bricking plant, etc., and in the case of reverberatories, the blowers, if used, steam-engines, boilers, motors (electrical) and mechanically operated roasters, the latter being the large item.

To build an up-to-date plant of say 1,000 tons daily capacity, 500 tons to be treated in blast-furnaces, and 500 tons in reverberatories, the mechanical equipment for the blast-furnace will be about 75% of that necessary for the reverberatory. I wish to repeat again, under this head, that it is not proper to charge the mechanical equipment of a wet concentrating plant to either type, neither is it proper to charge the converting equipment. Many of our sulphides require no concentrating, and it will pay some smelters to sell their matte and not convert themselves.

5. *What are the comparative costs of power, labor, fuel, and repairs?*

An up-to-date reverberatory furnace, with boilers properly attached, should develop power beside that required to operate the roasters, drive the fans (if forced draft is used), and to make electric power to operate the motors for ore and slag-haulage. This may sound overdrawn to many, but I venture the prediction that it will not be long before one reverberatory furnace, burning 50

tons of coal per day (24 hours) will develop more horsepower than will be required to operate the engines, motors, calciners, etc. The power for a reverberatory plant was 40% that of a blast plant at Butte, and in Utah the boilers on one reverberatory furnace develop three times as much power as the blowers, roasters, and slag-haulage require. This is being done at the Bingham Consolidated smelter in Salt Lake valley. At Butte labor for blast smelting was 90% of the reverberatory. With slack coal at $4 and coke at $9 per ton, blast smelting was 92% of reverberatory practice. The repairs, after the first year's run on the reverberatory, will be much higher than on the blast. Figuring labor and material, it will be from 75 to 100% higher than the blast-furnace.

6. *What are the comparative amounts of capital tied up in furnaces of each type, and how does this affect the cost per ton of daily capacity, or of output?*

The tied-up capital will be interest on the values in the matte held in the blast-furnace fore-hearth and crucible, and the vast amount held in the reverberatory hearth. There are usually about 20 tons of matte tied up in the blast-furnace, and about 200 tons in the reverberatory, of 150 tons each. In the case of blast smelting, the interest would be too small to mention, while on the reverberatory it will seldom affect the cost to exceed $0.05 per ton. There should be an interest gain by the amount of matte tied up in the reverberatory, as it aids the smelting. In other words, it is the key to fast smelting. In the blast, it does not affect the smelting.

7. *What are the limiting necessities in the way of fuel for each type?*

Coke for blast-furnaces with not over 15% ash. However, we are compelled to use a much higher ash many times. I have used to good advantage a mixture of coke carrying from 10 to 27% ash, but I cannot recommend it. For reverberatory smelting a bituminous coal, with long flame (such as the Rock Springs, Wyo., product), is preferable in Utah and Montana. The coal should determine the length of furnace to build. It is good practice to build the fire-box too large, as it will be easier to make it smaller than to enlarge it. Oil is in the experimental stage yet. Wood is a thing of the past in the West, and could not be used in our large furnaces of today.

8. *What are the comparative losses in slag, dust, or middle products?*

While the losses in both types is comparatively the same according to the natural slag-making elements, the difference is quite in favor of the reverberatory, owing to the vast amount of barren lime and iron used in the blast-furnace charge. There will be comparatively no loss in flue-dust or middle products, when we are allowed to build proper dust-chambers, flues, and stacks, which has not been done in the United States yet, and I cannot find words strong enough to say that the interest on these three investments is the best of the whole plant.

9. *What are the defining limits of each type in regard to slag composition?*

In Butte I was compelled to run on a very silicious slag on both the blast and reverberatory, but I do not think it good practice to have the SiO_2 over 45% on the blast-furnace. One can run on a much higher silicia in the reverberatory furnace than in the blast. It is not necessary to combine all the SiO_2 in the reverberatory, while it is desirable to do so in the blast-furnace.

At Butte, blast-furnace slag usually ran about 46% SiO_2, 26% Fe, 16% CaO, and about 0.3% Cu. The reverberatory slag usually ran 50% SiO_2, 30% Fe, 5% CaO, and about 0.4% Cu.

10. *How do these differences in slag figure out in financial margins per ton smelted?*

Making the same grade of matte, the blast slag will usually carry less values than the reverberatory, but this is more than made up by the greater amount of slag made, due to the addition of barren flux. The main difference in the composition between the two slags in the Butte district is in the lime content, so considering only the slag, the blast is the more costly to make.

11. *What method of charging do you advocate for a copper furnace (assuming the atmosphere to be oxidizing)?*

By all means employ side-dump cars, of which there are many excellent types for blast-furnace charging, and hoppers for reverberatory furnaces, set in such a position as to spread the charge properly.

12. *Would you bind, in some manner, all fine for use in the blast-furnace? Incidentally, what are the difficulties of treating fine ore in the blast-furnace?*

I would not bind any fine ore that could be treated in a reverberatory furnace. I have seen only one good binder; that was slime, made from wet concentration on Butte ore. The difficulties of treating fine ore in a blast-furnace are too well-known to need much comment: First, it limits one to the amount of wind necessary for fast driving; second, too much flue-dust is made; third, it forms dead spots in the ore-column, as well as crusts on the sides and ends of the furnace walls; fourth and last, it creates kicks from the farmers that can be heard from one side of the continent to the other.

It is gratifying to the writer to note the interest taken nowadays in the reverberatory practice. It was only a few years ago that I can recall a class of students visiting a smelting plant where I was employed in Montana, and the superintendent boldly told those young men that the reverberatory furnace was a thing of the past, and he would not build another one of them, under any consideration. Let the old, as well as the younger men in the business, weigh well all the above questions, before deciding on either type. It will no doubt appear to many of our friends that I have favored the reverberatory furnace in my answers. Such is not so; having practiced with both types for over twenty years, in the West, I fully realize the worth of both.

On Butte ores, I would treat 60% of the ore in blast-furnaces, and 40% in the reverberatory. On the sulphides in this district, I would treat 75% of the ore in reverberatory furnaces, and 25% in blast-furnaces. However, it can all be treated successfully in a complete reverberatory plant, owing to its fineness.

HARRY L. CHARLES.

Salt Lake, December 25.

Individual Stamps.

The Editor:

Sir — In response to Mr. Bosqui's inquiry, I can contribute the following experience with this type of stamps. The mill in question is of 18 individual quadruple-discharge stamps of a well-known maker, driven by three cam-shafts having the bull wheels in the middle, with a set of three stamps on each side. The mortars of each set of three stamps are cast as one solid casting, with tops and bottoms together, and occupy one base; this arrangement is similar to, and takes the same space as, one five-stamp battery.

The inventor recommends his own feeder, the usual square hopper tapering down, which delivers into a shaking chute actuated by an arm struck by a feed-tappet on the stem. These feeders work fairly well on dry coarse ore, but as a large part of that being treated is a fine oxidized material, more or less wet, it sticks at the bottom of hopper and the shaking chute packs it, cutting off the feed; one man is constantly poking the

feeders open, and it is hard to get a man who can keep the stamps from pounding. A five-stamp Challenge would feed this ore without trouble, but it is questionable if an individual Challenge would do so, on account of the smallness of the hopper-bottom that delivers to the revolving plate. A disadvantage of individual feeders and mortars is that ore must be crushed very fine, whereas in a large mill of the old style, during a breakdown of the rock-breaker, I have seen ore sent through with little trouble that ran up into occasional slabs 4 by 10 by 16 inches.

The placing of the bull wheel in the middle of the cam-shaft gives smoother running and less pounding of end boxes, but it has been found impossible to keep the bull wheel keyed tight to the cam-shaft. As contact parts are hidden by the battery-posts, the looseness is not apparent at first, and to key it again is quite a job; often the stamps have to be inclined out and the shaft raised. As such trouble will occur in most mills, it is advisable to place the bull wheels at the end of the shaft as usual.

The stamps weigh 1,250 lb., dropping 130 times per min. when set at 5¼ in. This is an unnecessarily heavy stamp for a soft or friable ore. The manufacturers of individual stamps advise extra heavy stamps with a fast, and consequently short, drop. The fast drop is absolutely necessary to get capacity by keeping the pulp moving over the screen surface, but this fast drop tears the battery parts and frame to pieces. With the old-style battery, careful experiments in many representative mills has demonstrated that the weight of the stamps and the rapidity of drop can be carried too far.

One trouble has been that the mortars fill up and have to be dug out; this occurs largely with soft fine ore, and to some extent with hard ore, even with the most careful feeding. It is impossible by any practical means to keep an even height of discharge, and it is not attempted; consequently, when new dies are put in there is a tremendous wear and tear on screens, as there is at all times. With 72 screens to look after, one-third of which can hardly be inspected, the conscientious millman has the time of his life.

In feeding a mixed ore the discharge is uneven, which is due to the feeder and mortar, the soft ore coming through first, the hard ore following. This does not occur in the old style with careful feeding. To get capacity with the individual stamp it is necessary to use an enormous amount of water; this swamps the plates, unless there is a special arrangement. At this mill, two sets of parallel plates are used to each three stamps, but it is impossible to get such an even flow as where plates are the full mortar-width and directly in front. There is little opportunity in a practical way to put a strip down the middle of a plate and rub up without turning off some of the water entering the battery and turning the pulp down one-half the plate, as is customary on low-grade and largely concentrating propositions. Inside feeding of quicksilver was not a success, and as plates cannot be kept in as good a condition by outside feeding, many dressings are required, and rubbing 12 plates for 18 stamps is stretching it.

Undoubtedly one individual stamp requires almost as much attention as a five-stamp battery. It might be advisable to increase the number up to 12 stamps; there are old-style mills in which one man runs 60 stamps. The advantages of the individual stamp are a larger capacity and fewer slimes, but the gain is much less than is usually supposed. As we either treat our slimes or run them to waste, the slight increase with the old style is usually of little consequence in comparison to the other advantages. Coming to capacity, in the old-style battery there are 500 pulsations given the pulp in the mortar per minute, naturally the finer and slimier material is kept in suspension to be washed through the screen, while the coarser remains to be crushed. In the individual, there are only one-fourth the pulsations and they are more violent — to the detriment of the screens. During the interval of drop the sand settles down on the die, the water is first forced out, if there is much height of discharge; then the sand is mashed and hurtled through the screens. In comparing the two styles, study the mortar action. If it is large screen-area we want, why are so many double-discharge mortars working with their back closed up?

If you want capacity it will pay to put up a greater number of five-stamp batteries than to put in individual stamps. The extra cost will only be for battery parts and power; 30 stamps could be put on the foundations of our 18 individual stamps. Figure out how many extra stamps the less cost for labor and screens, and loss of time putting in screens, minus the actual increased cost for power, over a period of one year, will put in. And remember, in the five-stamp battery you have a machine that is practically never replaced entirely by some other machine, but has replaced every other machine built for the same purpose. Ask the millman of experience with both types who knows the average milling conditions. Millmen have come to take a shift on this mill, and refused to go to work on seeing it.

In regard to the large individual stamp-mill — for concentration only — now being erected in Utah, the ore is a medium soft porphyry seamed with rotten quartz in which copper sulphides lie. As it is an ideal wet crushing ore, easily disintegrating, it is no wonder a high stamp duty — 10 tons through 28 mesh — was obtained in the experimental mill. For this particular ore the type of stamp selected is undoubtedly the best. It remains to be seen whether a stamp-mill crushing to the maximum fineness in one operation or the usual concentrator of rolls, grinding mills, jigs, etc., crushing and sizing in stages should be used on this ore. A mill of this type is being erected alongside the stamp-mill to run on ore from the same deposit, and the comparative results are awaited with great interest.

AMALGAMATOR.

A Notable Subscriber.

As a rule we do not burden our readers with the recital of complimentary letters from our friends, but the accompanying communication seems to afford excuse for making an exception. Mr. Corbett became a subscriber on November 27, 1871, and we have taken care that he shall get the paper in the future. His letter follows:

ASHLAND, Oregon, Jan. 15, 1907.

MINING AND SCIENTIFIC PRESS,
Berkeley, California.

Dear Sirs — After 35 years of close companionship we come to the parting of the way, and feel that I at last must drop your valuable magazine, the MINING AND SCIENTIFIC PRESS. I much regret this necessity. I am very near my 81st birthday, and last summer I disposed of the most valuable set of engineering instruments to be found on the Coast.

I began practice February 1, 1857, at Snow Point, Nevada county, California; went home in 1861 to aid our Uncle Samuel; went to Montana in 1864, staying there 29 years; then to Oregon, 1893, and am here yet.

Wishing you unbounded success,

Very respectfully,

J. LESLIE CORBETT.

First subscription, Nov. 27, 1871.

Some Associations of Gold With Pyrite and Tellurides.

Written for the MINING AND SCIENTIFIC PRESS
By W. J. SHARWOOD.

Two recent contributions* to the MINING AND SCIENTIFIC PRESS have referred to the relations between gold and pyrite in quartz veins. The accompanying drawings and notes illustrate some other occurrences of the kind.

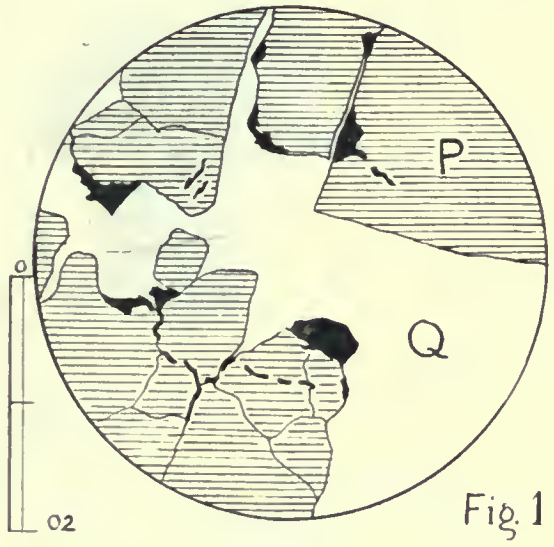

Fig. 1

When auriferous pyrite is graded by sifting, and the different sizes are assayed, two results may be observed: Either (1) the pyrite in the coarser portions differs but little from that in the fine, as regards gold value, which in this case is usually low, or (2) the value of the fine and coarse differ considerably. In the latter case my experience has been (excluding occurrences of very coarse gold) that the finer grades are invariably the richer.

This condition, of course, agrees with Mr. Smyth's results, and with his inference that the gold resides chiefly at or near the surface of the sulphide. For, if the pyrite grains have not been broken down, the finer particles necessarily present the greatest surface in proportion to their weight; while if crushed in a mill or mortar the surface material contributes first to the fines.

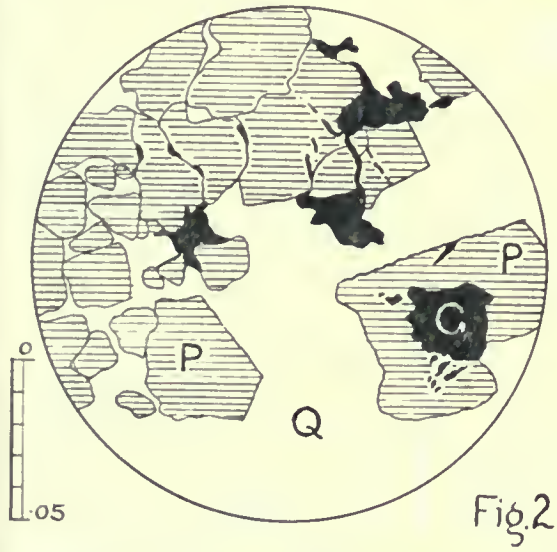

Fig. 2

Microscopic examination of a large number of specimens containing pyrite and visible gold in juxtaposition further confirms this view, and the drawings illustrate some of the conditions observed. In all cases thus tested at least some of the gold was found to be either at the surface of the particles of pyrite, or at a very small distance outside them, or else deposited in minute cracks in the pyrite. No grains of gold were found entirely enclosed in solid pyrite; in some sections gold particles were apparently surrounded by it, but examination during the grinding of the slides showed that these all extended to the surface of the pyrite grains or communicated with cracks. Of the specimens illustrated only one (Fig. 7) shows any trace of oxidization.

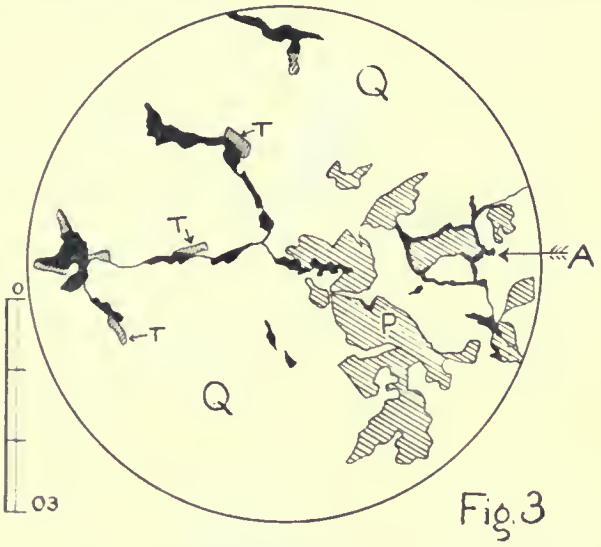

Fig. 3

DESCRIPTION OF SECTIONS.

The scale divisions are in every case hundredths of an inch; black areas represent gold.

Fig. 1 and 2.* Keltz mine, south fork of Stanislaus river, Tuolumne county, California. Quartz and pyrite, with gold (about 850 fine), and occasional specks of undetermined telluride. The pyrite is fractured, not appreciably oxidized, and the gold is at its surface or scattered along minute cracks. The thinnest sheet of gold accurately measured was 0.00015 in. thick, others were probably as little as 0.00005 in., the apparent thickness being increased by the grinding and polishing of the microscope slides.

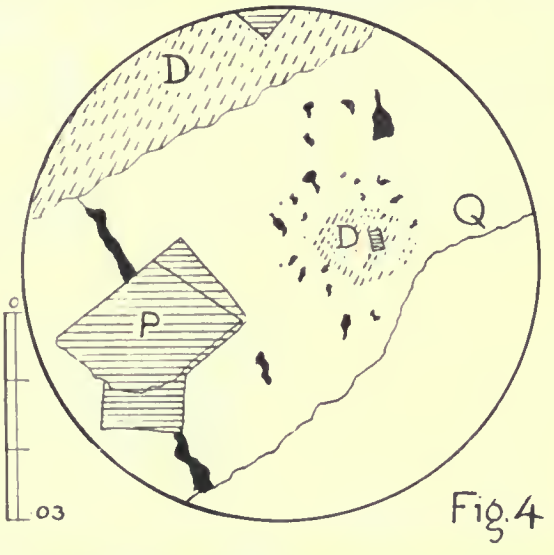

Fig. 4

This vein fills a fissure in carbonaceous slate, and is usually accompanied by a narrow altered porphyry dike carrying small cubes of pyrite containing only a trace of gold. The vein and walls show evidence of great pressure and repeated re-opening. In parts the quartz is

*H. L. Smyth, July 14, 1906; W. Lindgren, August 15, 1906.

*The veins yielding the ores shown in Fig. 1 to 5 closely resemble some of the Grass Valley veins, both in structure and mineral contents. Fig. 1 especially may be compared with Lindgren's illustration of ore from the Omaha mine (17th Ann. Rep. U. S. Geol. Survey, Vol. II, plate V), which is reproduced in Spurr's 'Geology Applied to Mining,' page 300.

ribboned or sheeted, gold being found with flattened pyrite in the dark seams. Polished black slickensides are frequent.

Fig. 3. From southerly portion of Soulsby mine, Tuolumne county, Cal. Milk-white quartz from 10-in. vein in granodiorite, with pyrite, gold (875 fine), and particles of bismuth telluride. The quartz grains are relatively large, many 0.1 and 0.12 in. across, very full of minute enclosures, which show a tendency to lie in lines or zones parallel with their length; these zones are continuous across the crystalline grains shown by the polariscope, and are independent of the crystalline structure. In this specimen the gold is all either in distinct cracks in the quartz (which usually communicate with pyrite or telluride), or is in contact with pyrite or telluride. At the point marked *A* a gold deposit entirely surrounds a grain of pyrite and another of quartz. After amalgamation the residual pyrite retains very little gold.

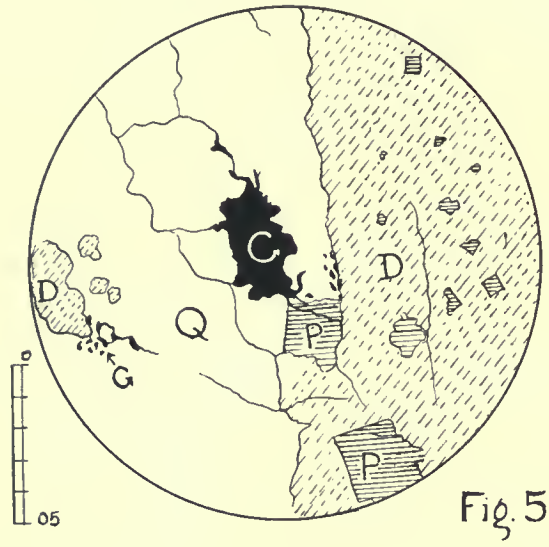

Fig. 5

In other parts of this deposit gold is found associated also with pyrrhotite, copper pyrite, zinc blende, and galena.

Fig. 4. South end of Soulsby mine. Gold and cubic pyrite in a ¾-in. stringer of compact white quartz, running through a dike of 'black slate' (*D* in figure; probably a sheared diorite-porphyry*). A large flake of gold occurs in a crack in contact with a pyrite crystal; smaller irregular particles surround decomposed fragments of pyritic 'slate.'

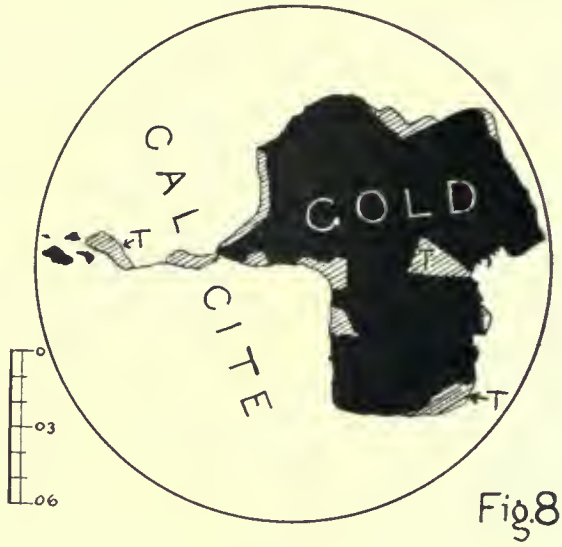

Fig. 8

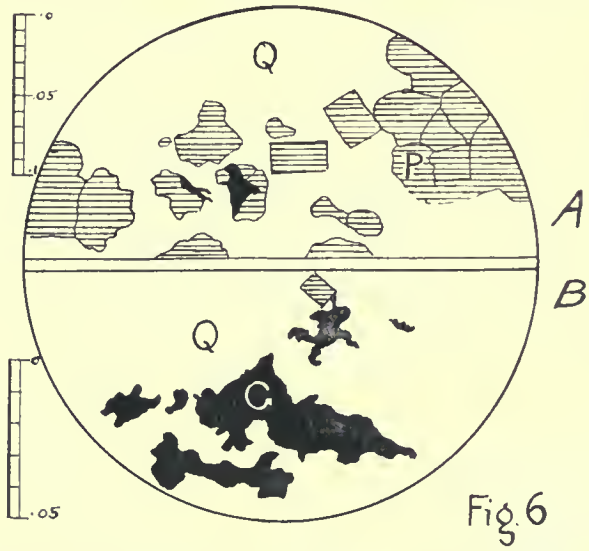

Fig. 6

Fig. 5. Same locality as No. 4. This shows a more usual condition in the veinlets which seam the silicified 'black slate' dike at this point; gold having developed in the quartz (which is free from pyrite) in the immediate vicinity of pyrite which has developed in the 'slate' (*D*), this pyrite being itself very poor in gold.

Fig. 6. From Hashidate mine, Echigo, Japan. Gold in white quartz, in some portions accompanied by pyrite. Most of the gold is, however, in masses in white quartz. Two sections shown were cut from the same specimen, at a few inches distance from one another.

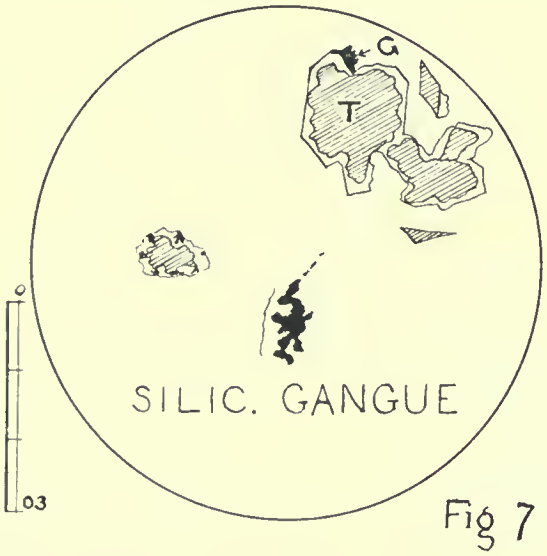

Fig 7

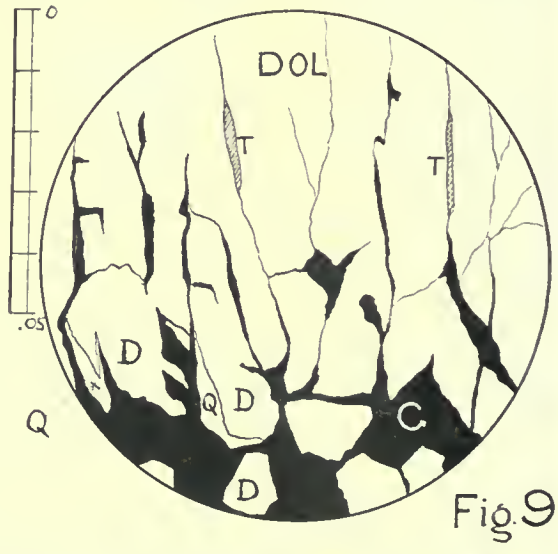

Fig. 9

Fig. 7. Gold and scattered grains of bismuth telluride, occurring in a much altered feldspathic rock, from the vicinity of Quigley, Montana. The very rich portions of

*F. L. Ransome, 17th Ann. Rep., U. S. Geol. Survey, Vol. I, page 677.

the deposit are hard and silicified masses, imbedded in a soft, clayey material which is poor in gold; both evidently resulting from alteration of a dike rock. All the gold is free, about 870 fine, and readily amalgamable; the telluride grains contain no gold or silver but are much corroded and superficially oxidized. A few small grains of oxide of iron are present, apparently due to oxidation of pyrite; these (not shown in figure) also carry free gold.

Fig. 8. Cable mine, Montana. Coarse gold with bismuth telluride in calcite; the telluride is mostly found surrounding masses of gold or in cracks in the calcite, but some crystals are enclosed in gold.

Pyritic ore of lower grade occurs in the same deposit accompanied by dolomite. The deposit is associated with a black intrusive rock, specimens of which were found to consist of olivine and magnetite in about equal proportions.**

Fig. 9. Jumper mine, on Mother Lode, Tuolumne county, Cal. Part of cross-section of veinlet or stringer of gold and dolomite in a dark pyritic slate. The pyrite in this slate is of very low gold value. The dolomite veinlet itself is from ½ to ¾ in. across, and contains a very small amount of an undetermined telluride, about 5% of

Fig 10

quartz, and from 3 to 10% by weight of gold (867 fine), though the appearance when broken indicates much more, owing to the toughness of the gold flakes, which fill the spaces between the dolomite crystals and completely surround some of the grains. Some of these flakes are much less than 0.0001 in. thick, and readily float in water when the carbonate is removed by acid.

The order of deposition is apparently: Dolomite, telluride, followed by gold and quartz.

Fig. 10 shows a less magnified complete cross-section of the same stringer.

Fig. 11. Sections across branches of a crystalline intergrowth of free gold and lead telluride (altaite) from Birney pocket-mine, Sawmill Flat, near Columbia, Cal. This was cut by imbedding the specimen in melted sealing-wax and grinding off a face. The altaite is nearly pure lead telluride, containing no combined gold. It and the free gold, which is 920 fine, appear to have been deposited at the same time. Both show crystal faces of cube, octahedron, etc.

In the ores represented by Fig. 1, 2, 3, and 6A gold has apparently been precipitated from solutions by contact with the pyrite, though no corrosion of that mineral is perceptible, and the quartz shows no iron stains whatever. Fig. 4 and 5 suggest deposition by the influence of the pyrite, but at a short distance from the precipitant, either by electrolytic action or as a secondary effect—possibly by hydrogen sulphide or ferrous sulphate resulting from the action of an acid solution, or of oxidation, on the iron sulphide, though in this case again no evidence of oxidation can be seen. In Fig. 7 we have precipitation of gold accompanied by the oxidation of a barren telluride. In Fig. 11 gold and a barren telluride of lead seem to have been deposited simultaneously or alternately by the same agency, but there is no evidence as to what the agent may be. In Fig. 8 the same conditions may hold. In the latter specimen, however, it is possible that the telluride may have been the precipitating agent; the grains of bismuth telluride were too small to determine positively whether they carried any combined gold, but if so, the percentage must be very small.

The above instances of gold-tellurium ores must be distinguished from true gold tellurides, such as the calaverite and sylvanite found in certain localities in California, Colorado, and Western Australia, in which the gold is or has been actually combined with tellurium. On the oxidation of such minerals the gold is set free, but frequently in a porous or finely divided condition.

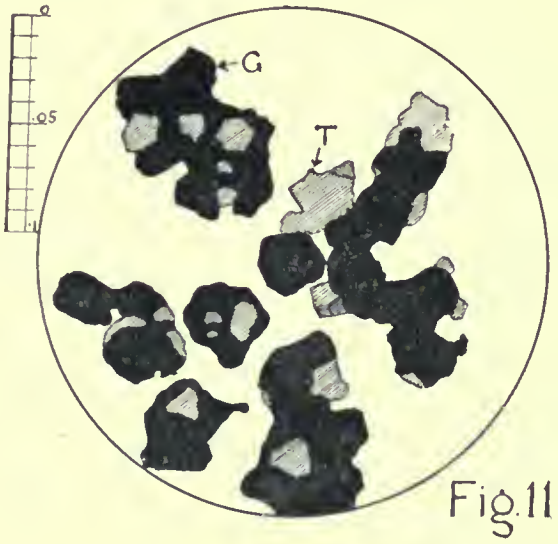

Fig.11

Laboratory experiments with pure minerals and preparations showed that the sulphides and tellurides of bismuth and lead, as well as the various minerals known as 'pyrites,' are very active in precipitating gold from its solutions—both acid, neutral, and alkaline. In general, the acid and neutral solutions gave deposits more brilliant and 'metallic' than the alkaline, which were often brown and more or less spongy. Pyrite cubes, and other minerals containing iron, commonly gave irregular deposits, the gold growing from a few scattered spots; the lead and bismuth minerals, on the other hand, usually became gold-plated over the entire surface soon after they were immersed in the gold solutions, if these were acid or neutral in reaction, and were more rapid precipitants than pyrites. Pure zinc-blende precipitated gold with extreme slowness but impure specimens were more effective.

MOISSAN has found that, at its boiling point, copper dissolves graphite, and, upon cooling, the graphite is given out again in the form of more or less well-defined crystals. This fact may explain the small black specks occasionally found in the fracture of brass castings. At the usual brass-melting temperature there is, undoubtedly, little absorption, but in over-heated metal it may be possible that the dissolved graphite plays a more important part in weakening copper and its alloys than is usually supposed.

**Described by W. D. Bohm as magnetite, *Mining Magazine*, May, 1906.

Mining Conditions at Ely, Nevada.

Written for the MINING AND SCIENTIFIC PRESS
By EDWARD W. RALPH.

Anyone who has lived for any length of time in the West or has come in contact with old-time Westerners in any part of the world has heard of the White Pine excitement in eastern Nevada in the late sixties. Gold was discovered in White Pine county at that time, and hundreds of men, having had their cupidity aroused by the various excitements and rushes which had been taking place on the Pacific slope with more or less frequency from '48 to the discovery of the Comstock, years after, were unable to restrain themselves when the word was passsed that there was gold in White Pine. Stories of wealth to be gained and sudden fortune to be acquired appeal to everyone. True, everyone does not rush to new 'diggings' at the first rumor of discovery, but the majority of the old-timers were found in almost every rush, provided the rumors regarding it were sufficiently persistent and elaborately embellished in detail.

Thus it was in the White Pine rush. The magic words 'gold in White Pine' was the slogan that caused otherwise level-headed men to drop the 'bird in the hand' to wander, aye, and to suffer, in search of the mythical 'two in the bush.'

As near as we can learn, in regard to White Pine, however, the prizes were miserably small and few in number. There was gold, it is true, but in such meagre quantities that it neither warranted an excitement nor maintained a camp of any consequence after the rush was over.

The town of Ely came into existence about this time, and managed to maintain a precarious existence, partly due to its situation, on the edge of the Steptoe valley where a little ranching was carried on, and partly because it was a supply point for the few miners who had the hardihood to stay with White Pine, and hold on to the claims they had located, hoping that some day they would become valuable. Monuments to the enterprise and tenacity of these pioneers are still in evidence in the form of mills and kindred reduction plants that bear silent witness to the grit of these old-timers, who had the courage of their convictions, however mis-applied and ill-directed their efforts were.

Gold was the much-sought metal then; if the mines would not pay as gold producers, it was argued, they would not pay at all. Copper was recognized as being present, but its very presence was cursed as being a great evil and detrimental to the recovery of the precious metal. Mills and concentrators were erected, tried out, found wanting, and abandoned, and finally all hope of making White Pine a paying mining district appears to have been abandoned and the camp relapsed into that condition described by Mr. Cleveland as "inocuous desuetude."

A few years ago the attention of several experienced mining men was directed to the district in the hope that, with the healthy tone of the copper market and the large area of available ground, it might be found commercially profitable to work the ores on a large scale. Work was commenced and vigorously prosecuted on the present holdings of the Nevada Consolidated and Giroux companies, with a view to ascertaining the exact extent and assay-value of the orebodies known to exist. An experimental reduction plant was erected on the Ruth mine and work was pushed vigorously underground. Developments in this and adjacent mines showed that the orebodies were of such prodigious proportions as to stand without a parallel among sulphide copper deposits.

The Nevada Consolidated people have now connected the town of Ely with the Southern Pacific railway at Cobre (a station 135 miles west of Ogden) by a standard-gauge railway 150 miles long. This road is now being extended from Ely, through Robinson cañon, to the mines of the company.

It is stated that a large smelter is to be built to treat the ores of this company, but nothing tangible in this direction is, as yet, in evidence. The Giroux company has a 100-ton smelter built and the Taylor Engineering Works is now building a 500-ton concentrator for this company. The Giroux people are working five shafts, the ore being placed on the dump to await reduction facilities. The extent of the copper-bearing zone already proved is about six miles long by two miles wide. West of the Giroux company's holdings are situated the mines of the Cumberland-Ely Co., now said to be absorbed by the Nevada Consolidated. Of this group of claims the Veteran mine is where most of the development has been done and the ore exposed therein appears to be of a higher copper tenor than in the mines farther east, while the real extent of the ore is unknown, although hundreds of feet of openings have already been made.

As to the geology of the district and the genesis of the mammoth copper-bearing orebodies, many different theories have been advanced. Mining men coming here with preconceived ideas relative to mines and mining as they occur in other places have been compelled to admit that it is a new one on them, and then do some thinking. The country generally, aside from where the gossan protrudes, is covered with either lime or rhyolite; the gossan is, of course, barren of copper, but has some gold in places. The copper-bearing sulphides—usually either chalcocite or chalcopyrite—occur in a quartz-porphyry matrix at a depth varying from 75 to 250 ft. below surface. The quartz-porphyry may occur with or without a paying copper content, but it seems that when pay-ore is encountered it is invariably associated with this quartz-porphyry.

Many of our regulation phrases, such as dip, strike, foot-wall, hanging wall, etc., will have to be quietly laid aside and forgotten here. As far as development up to this time indicates, none of these terms can be applied to the orebodies in question. As far as the exploration to date shows, they may be simply referred to as 'deposits', of no particular dip, and, while the proved ground would seem to show that the general trend of the ore-zone is easterly and westerly, this is simply because almost all the work done up to this time has been confined to where the gossan appears on surface.

Perhaps the ore was precipitated between the lime and rhyolite and these overlying formations subsequently eroded away, leaving the mass exposed here and there. The very immensity of the orebodies would seem to preclude the theory of fissuring and subsequent filling, and indeed no distinct fissuring can be detected except in places remote from the known orebodies. Whatever the genesis of this colossal ore-zone may have been, the fact of its existence and magnitude is plain to anyone who comes here, and of its possibilities as a future factor in copper production, there can be no question.

Just a word as to labor and business conditions: Ely can be reached either by the Nevada Northern railway from Cobre on the Southern Pacific or by stage from Eureka, the southern terminus of the Eureka & Palisade railway, about 75 miles distant. If the all-rail route is chosen, the visitor to Ely, on alighting at Cobre, is at the mercy of the Nevada Northern railway, which mulcts him in the sum of ten dollars for carrying him from there to Ely, 150 miles south. When he gets to Ely and tries to get a room and is lucky, he may find a cot at his disposal for one dollar per night. He can now get a decent meal for fifty cents, although it was but a very short while since that it was almost impossible to obtain

anything fit to eat in the town. In common with the Western country generally at present, labor is rather scarce. Good mechanics, miners, and laborers are in demand. It is very difficult to obtain the necessary supplies to carry on mining. The only sure way to get what you want is to bring it in from outside, and this takes a long time, owing to a congestion of freight on the roads. The settlement is typical of a mining camp; whatever else is wanting, there is always whisky to be had. Ely is now entering the transition stage; tents are giving way to frame buildings and shacks to more substantial structures; nice residences and office buildings are being erected and hotels of no mean pretensions are going up for the accommodation of the traveling public.

That the town of Ely is destined to occupy a place among the mining centres of note in this country, there can be no doubt, and it is to be sincerely hoped that its citizens will not, in their mad rush after wealth, overlook those matters of sanitation, a pure water supply and other things of a kindred nature, which are so essential and indispensable to a healthy, progressive, and well-ordered community.

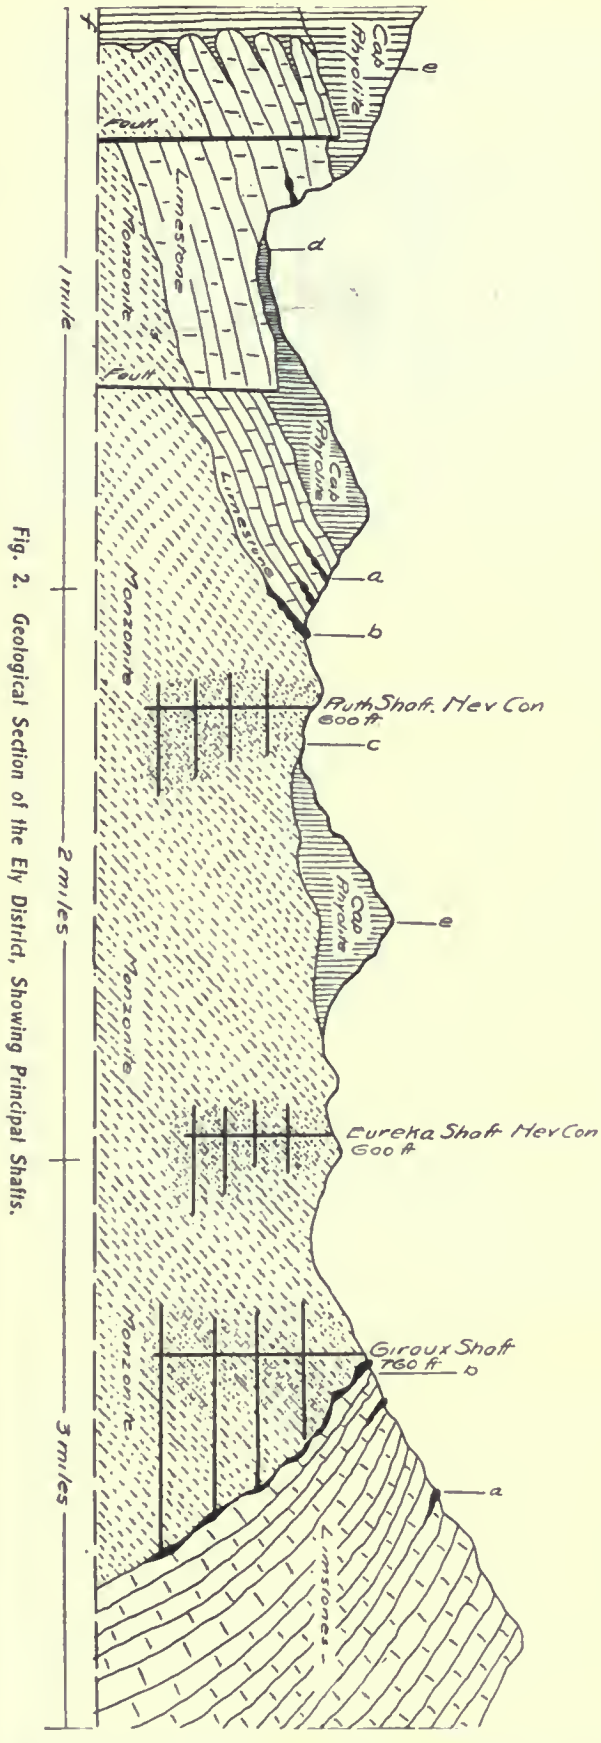

Fig. 2. Geological Section of the Ely District, Showing Principal Shafts.

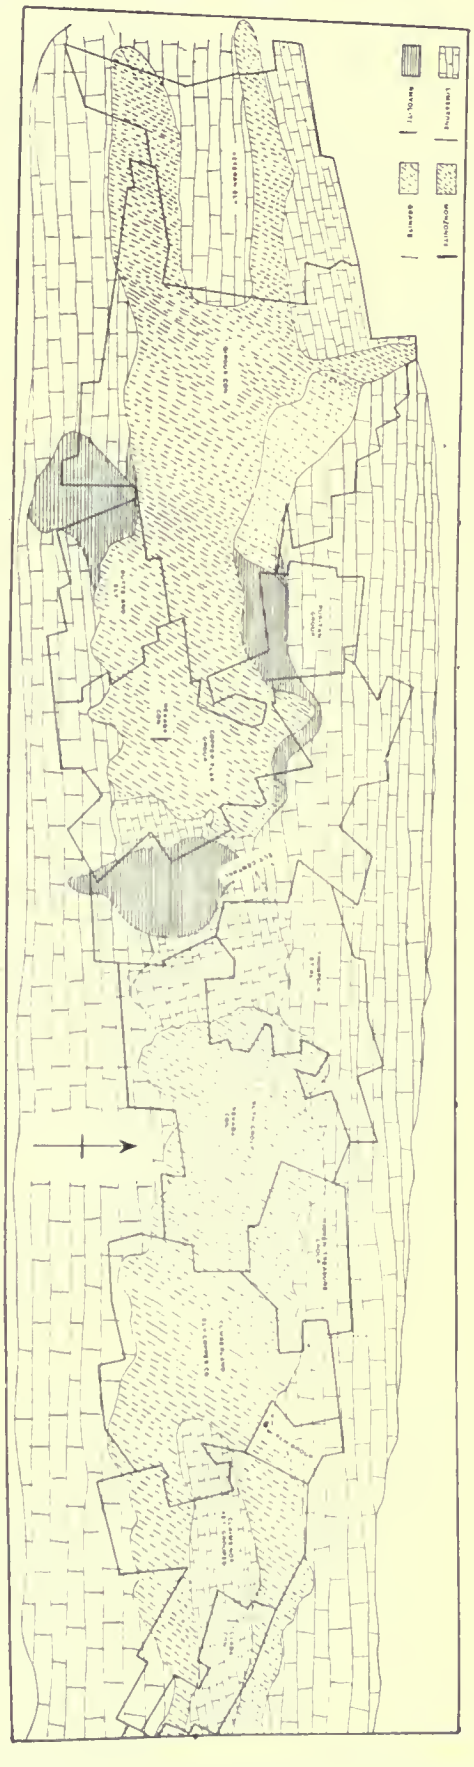

Fig. 1. Map of the Principal Properties of the Ely District.

Timber Preservatives.

One of the biggest expenses connected with mining is found in the timbers used to support the various gangways. Their destruction by decay and breaking costs many hundreds of thousands of dollars annually and in some cases the loss of human life. Mine operators are fully familiar with these facts. They know also that the seasoning and the preservative treatment of timber add to its life in service in the mine, but it has only recently been established by experiment that effective seasoning and treating with creosote, carbolinium, and zinc chloride can be secured at a cost so slight in proportion to the greatly increased life of the timbers as to effect a material saving.

In the loss of mine timbers at least 60 per cent are destroyed by decay and the remainder by crush. The percentage charged to decay should be even higher, because many of the timbers that break have already been weakened by decay.

Decay is principally caused by wood-destroying fungi. Warm, moist air, together with certain gases always found in mines, greatly favors the development of these fungi. Ventilation is an enormous factor. Timber in the vicinity of shafts and slopes where there is abundance of fresh air lasts longer than that deeper in the mines. The variation of moisture and temperature within mines is so wide that timbers may decay in eight months or may last several years. Timbers that are constantly wet or constantly dry last longer than those subjected to an alternation of these conditions.

Insects play a considerable part in the destruction of mine timbers. Many forms are found, including bark borers, ants, and timber worms. Their presence may be due to allowing logs to lie unpeeled after felling. Ants and cerambycid borers may attack props after they go into the mine. There decay spreads rapidly, and the destructive work of the insects appears to be in no way affected by the lack of light or by presence of gases. Creosote and carbolinium are effective insecticides and stop the work of the wood-borers.

The following data are based on experiments made in Pennsylvania under the direction of the Forest Service:

Various materials and methods for preservative treatment have been tried. Only time will show which are the most satisfactory from the practical point of view. Applied with a brush, creosote and carbolinium give an excellent penetration in solid wood, frequently averaging from one-fourth to one-half an inch. The amount of oil that seasoned loblolly pine takes from a brush application is surprising, especially in the end grain. Little difference in penetration has as yet been noted between creosote and carbolinium, though the latter seems better on absolutely green timber. All brush treatments were applied hot and in two coats. The second coat absorbed practically as much oil as the first.

Open-tank treatment has succeeded beyond all expectations. This consists of an immersion of the timbers for several hours in preservative and then allowing them to cool to atmospheric temperature. While the feasibility of the open-tank treatment has been demonstrated, there is much yet to be learned. The cost may be reduced by shortening the immersion and thus consuming less fluid. A heavy treatment is not necessary. The best preservatives approximately double the serviceable life of railway ties and may be counted on to do the same or better for mine timbers. Seasoned and treated props, which were put in alongside of the old-style props, unseasoned and unpeeled, are as sound as ever, while the others are already showing signs of fungous growth and decay.

Motoring in the Desert.

The antomobile is used generally all over the goldfields of the Nevada desert, in order to save time. Usually the charge for this service is $100 to $120 per day, but even the greater expense is an ultimate economy.

For example, an engineer who wanted to go to a certain locality would have been compelled to devote five days of travel if he had gone by stage-coach; by motor, it required only 11 hours of actual travel, so that he made the trip in one day comfortably.

ANNEALING STEEL.—If a piece of cast steel be allowed to cool freely from a casting temperature, there will be a grain or crystal growth proceeding to a certain point when the growth ceases. The metal in that condition will not possess its maximum ductility expressed as elongation and contraction of area. It will be more or less brittle, depending upon the carbon content. If that same piece of steel be re-heated to or about the point at which the grain growth stopped and allowed to cool slowly, the coarse grain developed during the first cooling will be greatly modified, broken up or obliterated and replaced by a finer grain than it had originally. In this new condition the ductility will be greatly improved; the metal will be tougher and better fitted for service conditions in any case than without a re-heating. Such a re-heating is, properly speaking, 'annealing.' The object, then, in annealing is to so affect the grains or crystals as to develop the maximum degree of toughness that a casting of a given composition is capable of developing.—*Iron Trade Review.*

CARNIOLA, in Austria, is a region of caverns, underground waters, and disappearing rivers. One of its most remarkable features is Lake Zirknitz, an irregularly shaped lake five miles long, whose waters disappear periodically for several weeks, or even months, at a time, during which interval the bottom is utilized for the growing of hay or other herbage. The waters are not regular in their disappearance, and have sometimes not retired during five or six years, but generally they drain off at the end of August. It takes from 20 to 25 days to empty the lake, but it re-fills suddenly and unexpectedly in as short a time as 24 hours. The phenomenon is due to the limestone character of the country, which is honeycombed by circulating waters. Numbers of fissures occur in the lake bottom, communicating with these subterranean channels, through which the waters are replenished or drawn off; 28 of these openings draw it off only, while 12 others discharge water into the lake as well as draw it off. Through the latter the water pours in after rainy weather as from a spout.

Old Mexican Methods.

Written for the MINING AND SCIENTIFIC PRESS
By BERNARD MACDONALD.

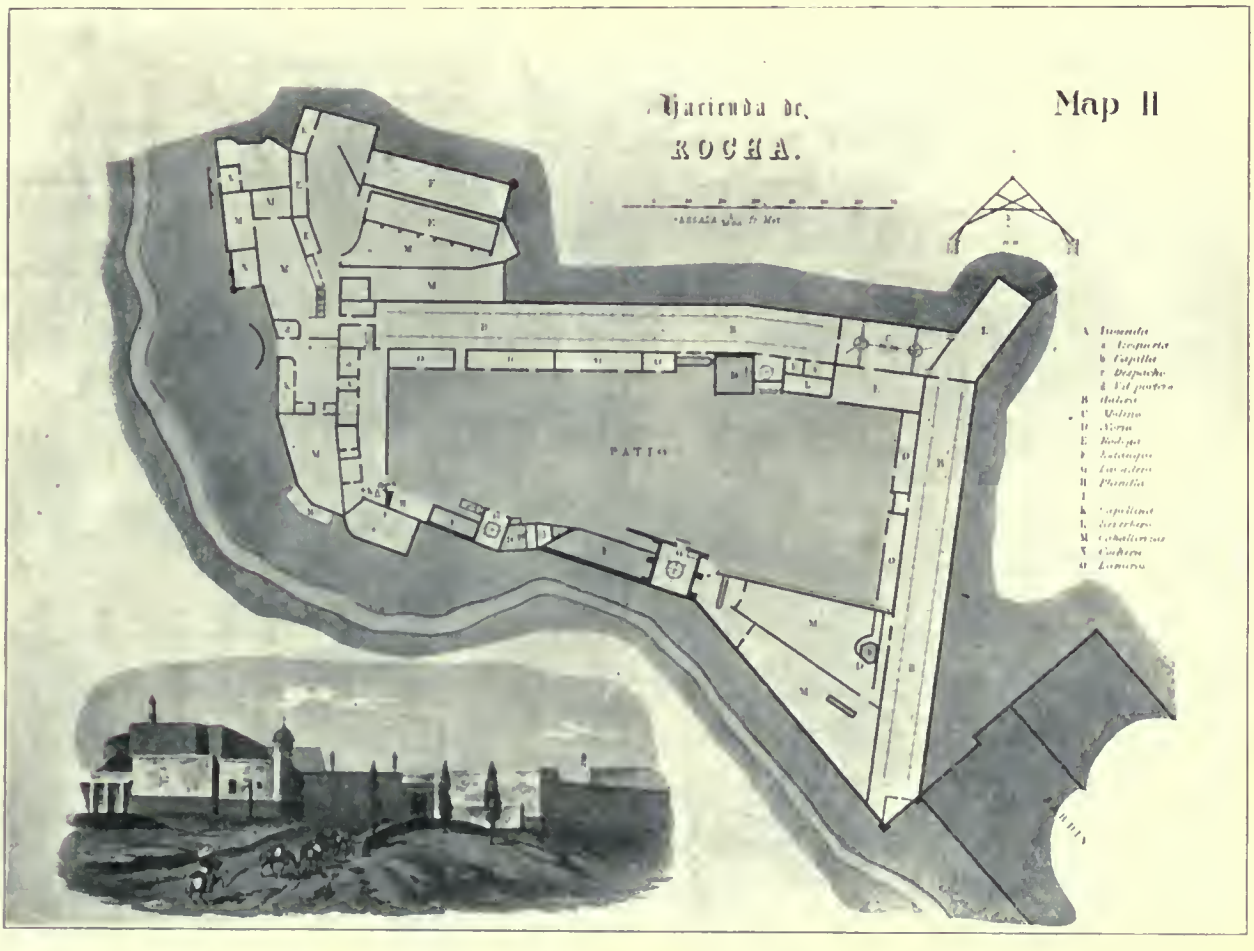
The accompanying plates were made to illustrate a report made in 1866 by Herr E. Tillmann, the Royal Commissioner of Mines in Prussia, and who had in 1865 visited Guanajuato at the instance of his own government to examine the mines of the district.

By way of introduction and historical interest to what may be said of the value of these plates, it should be known that Guanajuato was one of the first mining districts worked in Mexico after the Spanish conquest under Cortez in 1519, and that this district still holds the record of making the largest production of silver in the Republic. Owing to the enormous size of the ore deposits, rather than to the richness of the ore, the mines at Guanajuato were worked continuously, unless when temporarily interrupted by wars and revolutions, until depths ranging from 800 to 1,500 ft. were reached in the mines on the Veta Madre, or Mother Lode of the district. Then, on account of water, high treatment charges, and sundry other causes, the mines gradually became unprofitable and about '84 or some twenty-two years ago, practically all the deep mines were closed down.

In 1890 the Guanajuato Consolidated Mining and Milling Co. purchased the Sirena group of mines on the Veta Madre (See Map No. 1), this being the first American company to enter the field. It began to unwater the mines at once and afterward commenced regular mining and milling operations, substituting pan-amalgamation for the patio process. Not being satisfied with the results obtained from the treatment of their ore by pan-amalgamation, this company, in 1904, substituted for it the cyanide treatment. The results of this latter process being attended with highly favorable results, attracted the attention of American capital to the district and now all the prominent historical mines of the district are owned by American companies, and large milling plants with corresponding cyanide plants are being erected for the treatment of their ores.

From the number of mills already erected and in operation and those in course of construction, or contracted for, it is practically assured that by the middle of 1907, one thousand stamps will be dropping in the district and mining and milling will be carried on by the most modern methods. For this reason and in view of the fact that the former methods of mining and milling in vogue in Guanajuato for over 350 years will disappear forever and be replaced by modern methods, especial interest attaches to Plate No. 2 and 3 in question, giving, as they do, some idea of the plants and past methods used to win the silver from its ores.

Plate No. 1 shows the geology of the district as given by Herr Tillmann in his report. In the original plate the several formations were given in colors, but in the tracing that I am forwarding the original boundaries of these formations are shown in conventional signs. This plate also shows the three vein systems of the district, the Veta Madre or Mother vein, occupying the centre, the La Luz vein system lying three miles to the southwest and the Villapanda-Santa Rosa vein system about the same distance to the southeast of the Veta Madre.



The ores of the district are valuable for silver and gold, those of the Veta Madre containing 85% of their value in silver and 15% in gold; those of the La Luz system contain 75% of their value in silver, the remainder being in gold, while the ores of the Villapanda vein system carry a higher percentage of gold, so as to make 40 and even 50% of the value of their precious content.

Plate No. 2 shows the Hacienda de Rocha in plan and photographic view, the various departments of which are shown by letters and explanations in Spanish on the margin. This is a good example of a *hacienda* using the old *patio* system, some of the interesting mechanical departments being described in detail on Plate No. 3.

Fig. 1 on Plate 3 shows the old stamp-mill, with wooden stamps shod with iron, such as were, until recently, generally used throughout Mexico and operated by mule-power. After being stamped the ore passed to the *arrastre* shown in Fig. 2, where it underwent the process of fine-grinding. The pulp was then allowed to settle and thicken and subjected to the *patio* process proper, which consisted of mixing the pulp with *magistral* (roasted and

melted into bars. The several figures in this plate will explain the various processes without further description.

The sweeping changes which have taken place in the mining and milling practice in this famous old district illustrate again that in mining as in everything else: "By the wayside of progress lie the broken images of the past."

THE heaviest annual rainfall in the globe is over 600 inches, at Cherraponjee, in the Khasi hills, India; 500 in. fall from April to September during the southwest monsoon. On the basis of one inch of rain weighing 113 tons per acre, this latter quantity will amount to the astonishing weight of over 36,000,000 tons of water falling on a square mile within the period of five months! This is due to the abruptness of the mountains that face the Bay of Bengal, from which they are separated by 200 miles of low swamps and marshes. Over these the hot winds pass, absorbing the water to the point of saturation, and are ready to burst in torrents when first they meet the mountains in their path.

ground copper and marcasite), salt, and quicksilver, and exposed for a long time in the open air in layers called *tortas* on the *patio*. The pulp thus exposed was subjected to frequent mixing by a squad of mules being driven over it; then it was conveyed to the settling vats shown in Fig. 3, where it was thinned with water, which allowed the amalgam of silver formed by the mixture of quicksilver with the pulp on the *patio* above described to be washed out and settle in the bottom. Lastly, the amalgam was collected and distilled in the retort shown in Fig. 4. Fig. 5 shows the cast-iron hood raised from the retort as the process of retorting was completed, when the silver sponge formed therein would be removed and finally melted into bars.

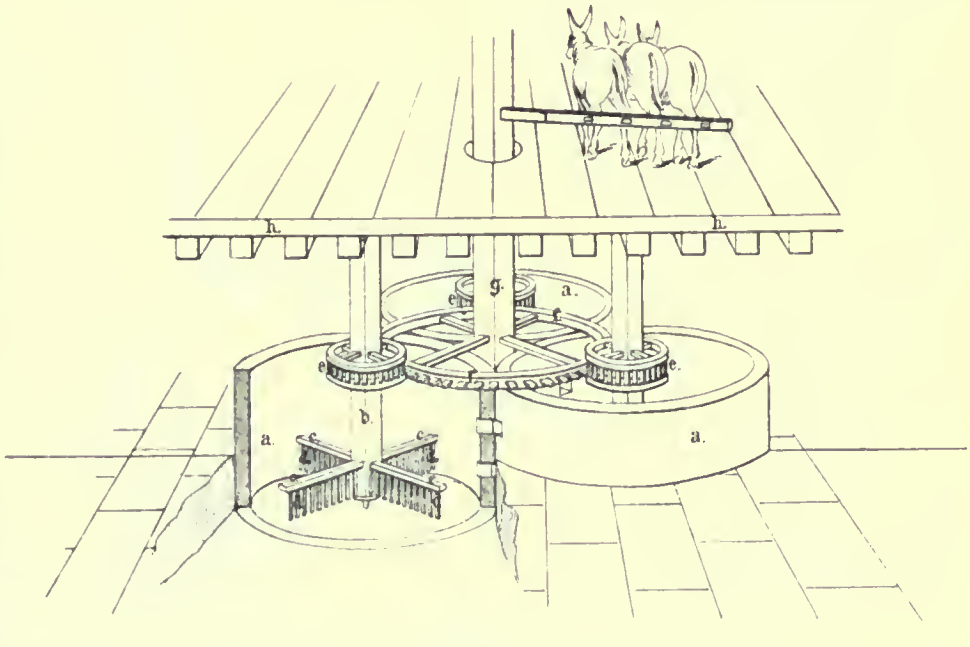

Fig. 3.

Temperature in Mines.

Some important investigations were recently undertaken in the deep mine workings and bore-holes on the Rand, which resulted in establishing the fact that there is apparently a uniform increase in temperature with depth, in that district, at least, of 1° for each 208 ft. below 1,000 ft., where the temperature is 68.75° F. It was also shown that the character of mine development has an important influence in lowering the temperature, not only of the mine air, but also of the rocks themselves to a distance of several feet from the mine opening, after continued exposure to air currents of a lower temperature.

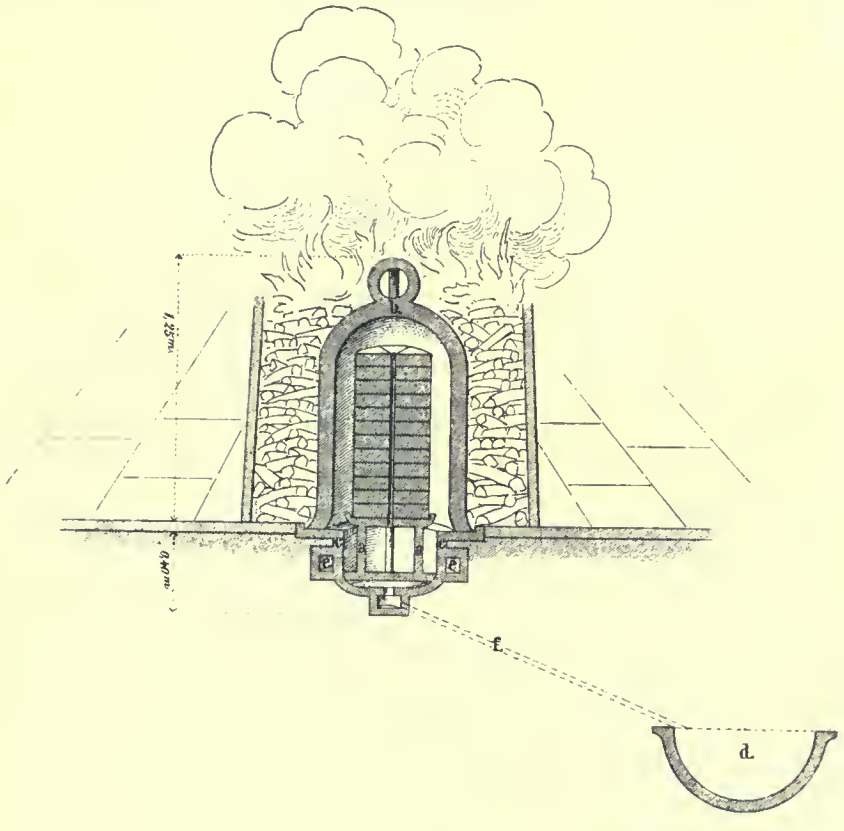

Fig. 4.

At Bendigo, in Victoria, Australia, a careful investigation proved the increase in temperature to be 1° for every 80 ft. in depth, a very noticeable difference as compared with that on the Rand. In the Dolcoath mine, in Cornwall, the increase of temperature is 1° for each 60 ft. of additional depth, a higher rate than that of Bendigo.

A number of shafts on the Mother Lode of California have passed below the 2,000-ft. vertical mark, one of them, the Kennedy, being nearly 3,000 ft., and the rate of increase of temperature is about the same as that on the Rand. No high temperatures have ever been noted in California gold mines, though in some of the quicksilver and copper mines of this State the temperature of the mine workings exceeds 120° at shallow depths, and, in at least one instance, a quicksilver deposit cannot be worked at all owing to high temperature, due to the occurrence of thermal springs in the mine workings, or in their immediate vicinity. In the copper mines referred to, it is wholly due to the rapid oxidation of bodies of sulphide ore. So rapid is this oxidation that the ore occasionally takes fire by spontaneous combustion, in the mine, and in a number of instances ore from the Daulton mine, in Madera county, and from Whiterock, in Mariposa county, have set fire to the cars while in transit to the smelter.

The great heat of the mine workings on the Comstock Lode, is due to either thermal springs, or to rapid oxidation (combustion) of the rocks in which the lode occurs; the second is likely to be caused by the first. Six miles west of the Comstock, similar springs occur at Steamboat, where cinnabar and other valuable minerals are being deposited. Attempts at mining have been abandoned there owing to the great heat of the water, though through almost superhuman endeavor a shaft was sunk in the travertine deposit to a depth of 50 ft. The water of the springs was found very corrosive, on account of the free sulphuric acid it contained.

The copper mines of Lake Superior are the deepest vertically in the world. The formation consists of a succession of lavas of extrusive origin with interbedded layers of sandstone and conglomerate. The temperature in the bottom of the deepest of these mines (a little over 5,000 ft.) is not excessive, being nearly the same as that on the Rand at equal depth.

It is not known that the geological age of the rocks in which ore deposits occur has any relation to the temperature found in the mine workings, but rather to the physical conditions obtaining in each instance. It is noteworthy, however, that the hottest mines, where the heat is due to thermal springs, are mostly in Tertiary lavas.

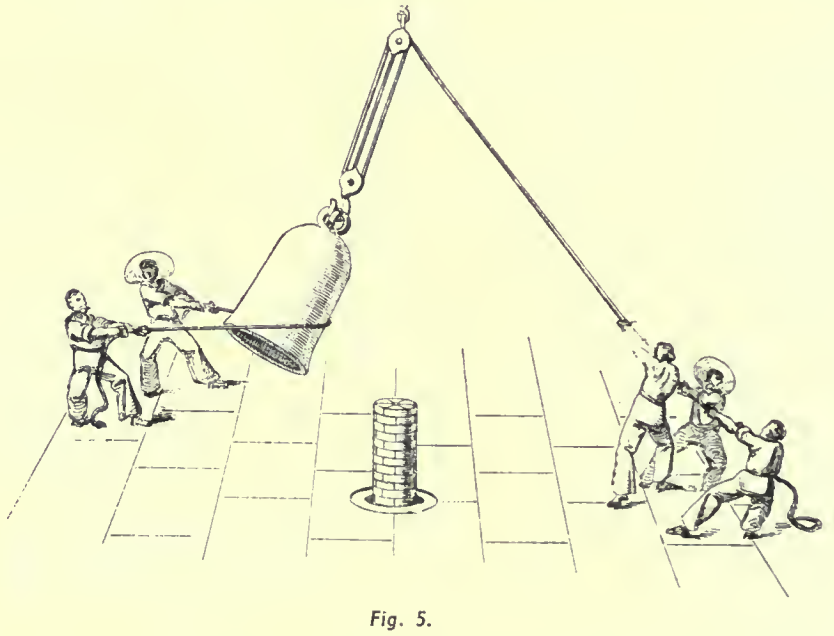

Fig. 5.

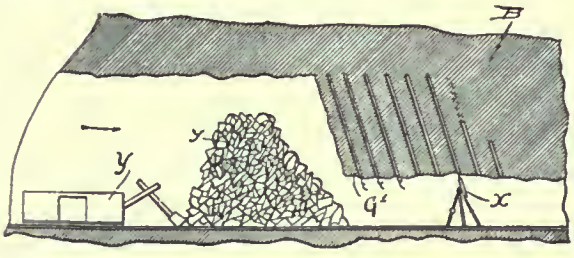
It has been observed that the air temperature in different parts of the same level of a mine varies from point to

MINING AND METALLURGICAL PATENTS.

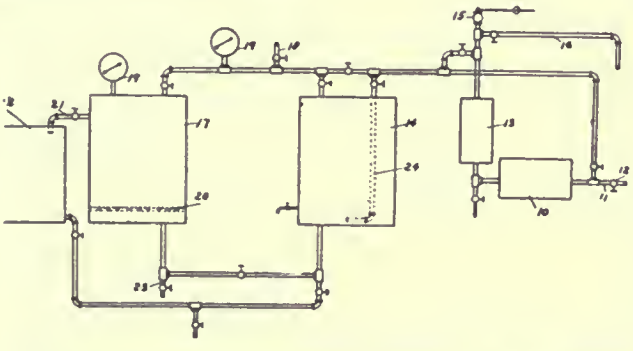
Specially reported for the MINING AND SCIENTIFIC PRESS.

METHOD FOR TUNNELING THROUGH ROCKS.—No. 840,307; Patrick Ford, Chicago, Illinois.



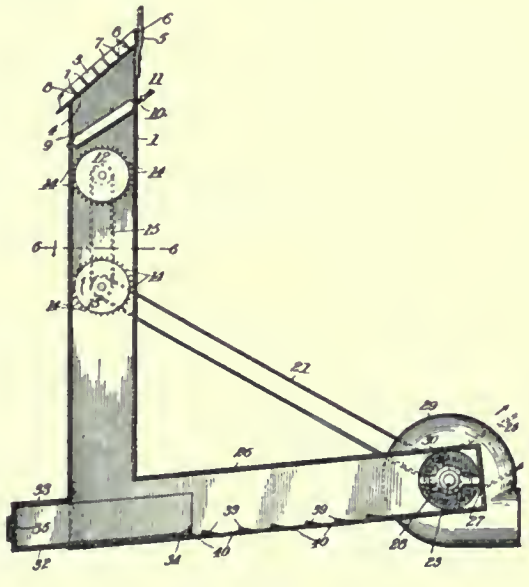
The method of excavating rock tunnels comprising first constructing an under heading for the length of the tunnel and then throwing down the material from the roof of said tunnel, into said heading and operating simultaneously at either or both ends of the tunnel.

CYANIDE PROCESS.—No. 840,840; Howard B. Goetschius, Dumont, New Jersey.



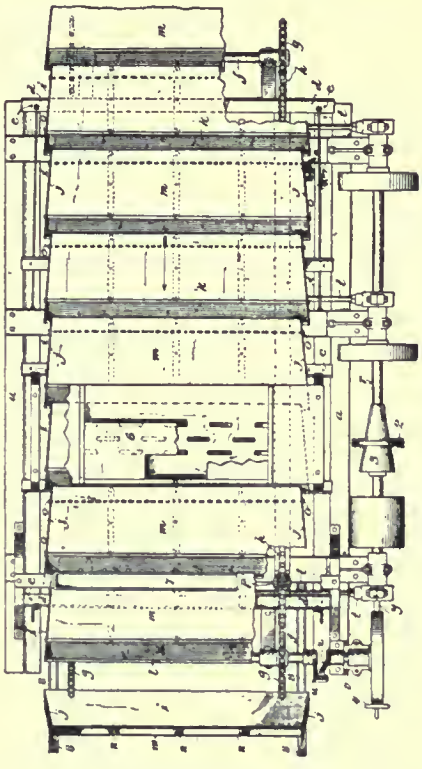
The herein-described cyanide extraction process, consisting in: First aerating the cyanide solution under pressure greater than atmospheric pressure; then forcing the aerated solution under said pressure through the ore to be treated and against a suitable back pressure.

APPARATUS FOR EXTRACTING AND SAVING GOLD.—No. 840,752; Joseph A. Coombes, Atlantic City, N. J., assignor to The Aurum Mining Company, Corporation of Arizona.



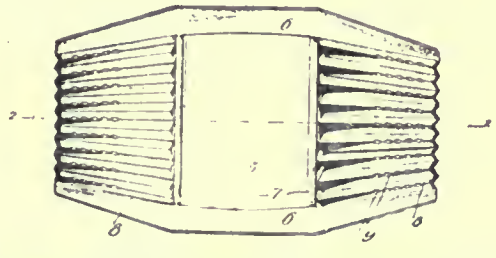
In a gold-saving apparatus, a vertical casing, an inclined hopper adjustably and removably mounted at the upper end of said casing, a pivotally-mounted inclined regulator within said casing beneath said hopper, a pair of cylinders mounted to revolve in unison within said casing beneath said regulator, and means for revolving said cylinders.

ORE-CONCENTRATING MACHINE.—No. 840,491; Henry C. Holthoff, Milwaukee, Wisconsin.



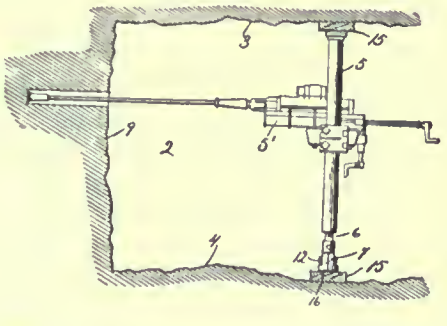
In an ore-concentrating machine, an endless belt having a series of shields attached to and movable with it and arranged with spaces between them over the working surface of the belt, and with a series of hinged leaves or sections having raised sides and adapted to lap one over another on the upper side of the belt, each leaf or section being provided with a shield partially covering its working surface.

MINER'S GOLD-PAN.—No. 840,333; Thomas Hussey, Hollywood, California.



A hand gold-pan having a portion of the upper part of the end walls corrugated and having perforations at the apices of the outer portions of the corrugations.

FOOT-PLATE FOR DRILL-COLUMNS.—No. 841,019; Arthur D. Kenyon, Cripple Creek, Colorado.



A foot-plate consisting of two parts of identical form, which may be used interchangeably, and the combination with a supporting-column provided with a jack-screw, of a foot-plate for the latter made in two parts of substantially identical form, and means which not only secure said parts together but hold the foot-plate as a whole upon said screw.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

The mining law of Montana provides that on all claims a notice must be posted at the point of discovery setting forth the following facts: (1) The name of the lode; (2) the name of the locator or locators; (3) the date of the location; (4) if a lode claim, then the number of linear feet claimed along the vein each way from the point of discovery, with the width on each side of the centre of the vein, and the general course of the vein, as nearly as may be. It further provides that before the expiration of 60 days after posting such notice the locator must sink a discovery shaft upon the claim at a depth of at least 10 ft. from the lowest part of the rim of the shaft, or deeper, if necessary, to show a well-defined crevice or valuable deposit. But a cut, cross-cut, or tunnel that cuts the vein at the depth of 10 ft. below the surface, or an open-cut of at least 10 ft. in length along the lode from the point where the lead is discovered, is declared to be equivalent to the discovery shaft. The Supreme Court of Montana, in speaking of the sufficiency of a notice under this statute, said that the requirement of the statute, that the notice must state the dimensions, could have no other purpose than to show a compliance with the law; "and while we do not say that the notice shall state definitely that the excavation cuts the vein to the depth or for the length required by the statute, yet the statement of the dimensions must be such as to leave at least an inference that such is the case, and a notice which fails to state the work done certainly does not conform to the spirit of the statute."

Helena Gold &c. Co. *v.* Baggaley, (Mont.) 87. Pac. 455.

The United States statutes provide that in an adverse suit, if the title to the ground in controversy should not be established by either party it should be the duty of the jury to so find, and that judgment be entered according to the verdict. The object of this statute is said to be, to provide that in the case of a failure of proof of title, for an adjudication that neither party was entitled to the property and that the applicant could not then go forward with the proceedings in the land office simply because the adverse claimant had failed to make out his case, if he himself had failed.

Brown *v.* Gurney, 27 Sup. Ct. 509.

The rules as to the location of mining claims do not exclude other prospectors from the area of the claim absolutely, but only prohibits the acquisition of rights within the area which would interfere or conflict with the right of the first discoverer to swing his claim so as to lay it along the lode after his explorations demonstrate its strike. The effect of this is that a subsequent explorer would go into such area at his peril. But the result would be that after the first discoverer had completed his work and located his claim, the junior discoverer ought to be secure in any location made by him in the meantime upon other portions of the area not in conflict with the rights of the first discoverer.

Helena Gold &c. Co. *v.* Baggaley, (Mont.) 87 Pac. 455.

The owners of four mining claims contracted with the complainant to develop what was termed the Anvil Creek property, which they owned, and the contract recited that the complainant should receive as compensation a certain per cent of the net output of two claims, naming them, and it further stated that the agreement should continue until 'said claims' were worked out. In passing on the validity of the contract and the rights of the parties the Court decided that the contract was ambiguous as to whether or not it included the four claims or only the two referred to, and that parol evidence was properly admitted to show that the Anvil Creek property was the two specified claims, and that a subsequent oral agreement had been made as to the other property.

Lindblom *v.* Fallott, 145 Fed. 805.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The specimen from Manvel, Cal., marked J. S. G., is a silicious rock, somewhat calcareous, and coated with green serpentine.

E. H. R., of Dixie, Idaho, sends black sand containing Magnetite, Ilmenite, Garnet, and globules of Mercury. The microscope does not show any platinum grains.

The red mineral and yellowish green coating from D. C. F. of Riverside, Cal., are the hydrous arsenate of iron, Scorodite, and they have probably been formed from the decomposition of arsenopyrite.

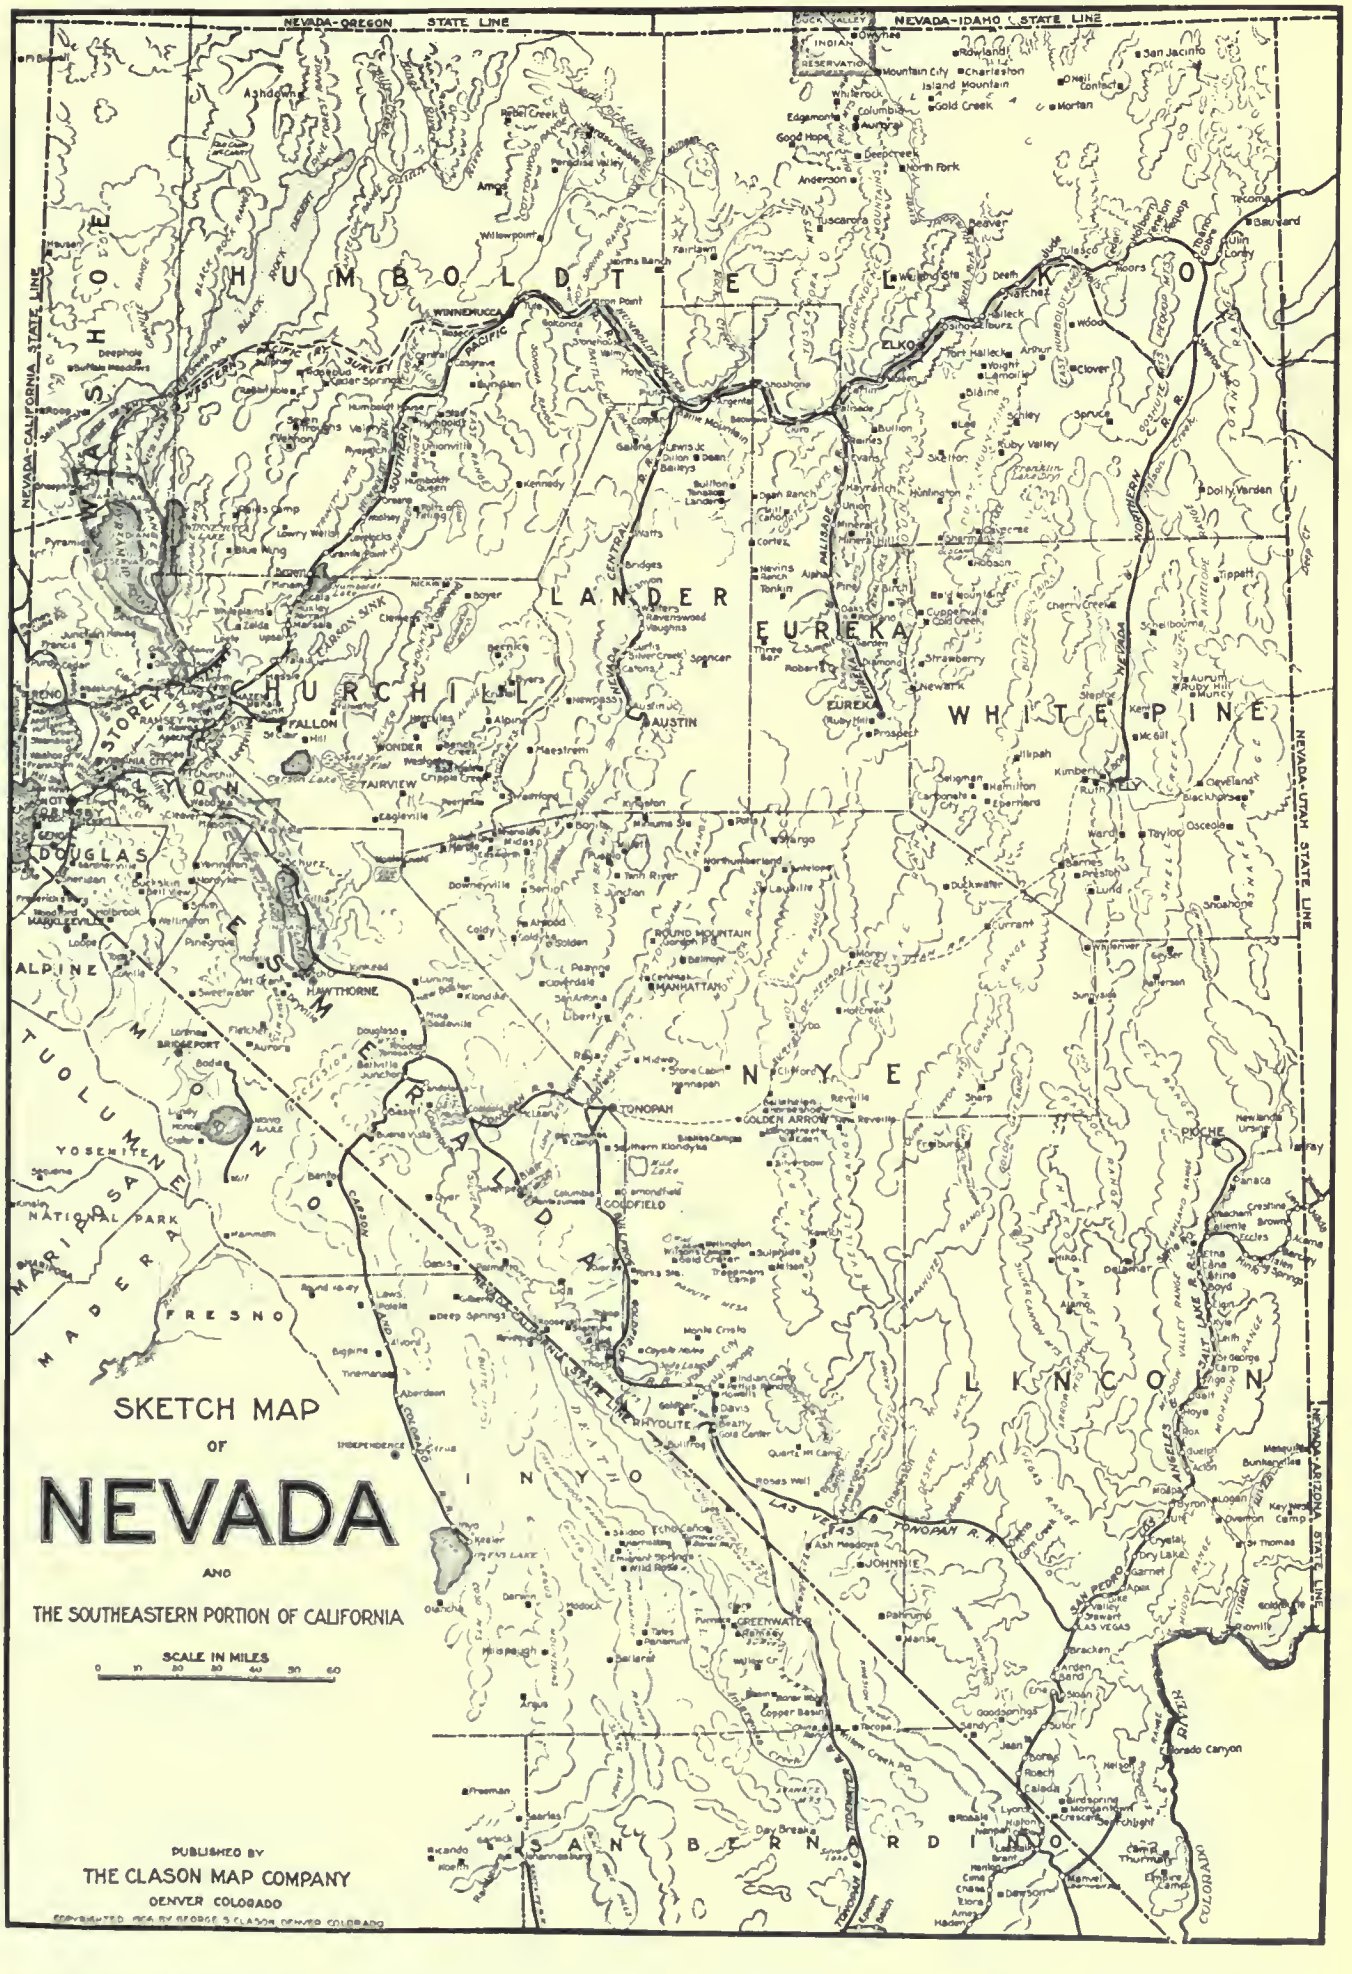
The minerals from P. H. B., of Wickenburg, Ariz., are: No. 1, a Zeolite, analogous in composition and properties to epistilbite, a hydrous lime alumina silicate; No. 2 contains fine granular black Hematite in matrix.

Specimens from T. P. G., of Alamos, Sonora, Mexico, are: No. 1, altered rock stained with Hematite; No. 2, Rhyolite; No. 3, Felsite; No. 4, Feldspar-Porphyry; No. 5, cellular Quartz with imbedded Pyrite and containing small yellow crystals of sulphur in the cavities.

The rocks from Homestead, Oregon, marked E. A., are: No. 1, serpentinized basic rock, probably Dioritic; No. 2, Granite, or Grano-diorite; No. 3, Felsite; No. 4, Grano-diorite; No. 5, felsitic rocks containing a little Cobalt bloom; No. 6, an altered volcanic rock; No. 7, Porphyrite; No. 8, Diorite.

SCARCITY OF PLATINUM.—All the platinum that has ever been produced from all countries of the globe, since the first discovery of the metal, would barely exceed 100 tons of the fine metal. You could put it all, in a single block, in a room 10 metres cube. The largest nugget of platinum ever found weighed 9½ kilos—about 20 lb. Never in its history was there so great a demand for platinum as today, yet, with the mining world keenly alive to its importance, with its double-the-price-of-gold present-day incentive, with experts searching for it here and there the world o'er, and mine-owners urging the output 'to the limit,' still the annual platinum 'crop' of the globe barely touches half-a-dozen tons. Three decades ago the value of platinum was $2 per ounce. Today it is above $32.

To most of us, indeed, the earth is still as flat as though Columbus had never sailed from Palos, and the relations and distances it reveals are often a shock. There are the Philippines, which we persist in regarding as lying just a step or two beyond Hawaii. There is South America, which, instead of lying decently south of North America, as its name would imply, persists in sticking out absurdly eastward into the Atlantic Ocean, so that a brick hurled due south by an enraged giant at Tampa, would skim right over Panama and plump into the Pacific. There is the Panama Canal itself, with its eastern terminus lying west of its western terminus. There is Cuba, which we instinctively locate somewhere southeast in the Atlantic, though Havana lies nine degrees west of the meridian of New York.—*Evening Post*, New York.



This new map of Nevada was furnished to us by the Clason Map Co., of Denver. A guide map for the pocket and a folding reference map on canvas can be secured from them or from us, the price bieng $1 and $5, respectively.

Portable Track.

The Arthur Koppel Co. makes a portable track, which can be removed in a few minutes by two men, before blasting. The track is mounted on light steel ties, and the rails are 50 ft. long, so as to allow them to be easily carried. For this portable track, rails up to 12 lb. per yd. can be furnished. The connection between the rails and ties is made by means of clips and bolts, this being the most suitable and durable way, but other systems can be furnished if desired, such as rivets, clutch-bolts, etc. The connection

between the different sections is generally made by fish-plates and bolts, but angle-joints can be supplied, if preferred. The carrying capacity of this portable track varies from two tons for a 9-lb. rail to seven tons for a 20-lb. rail. Switches and turn-tables are constructed so as to be easily removed without any disturbance of the road-bed. Light cars can be furnished, which are so designed as to be portable, and at the same time possess strength enough to carry the load safely. This makes a combination of equipment that may be easily torn up and removed to another part of the mine, with a minimum expenditure of time and labor. This company makes a specialty of charging cars, suitable for carrying coal, ashes, cinders, etc., to and from boiler-rooms. It also carries on hand a large stock of track materials, steel rails of all weights, standard types of wooden and steel dump-cars, flat cars, portable tracks, switches, frogs, turn-tables, wheels, axles, and other equipments.

Commercial Paragraphs.

STEPHENS-ADAMSON MFG. CO., of Aurora, Ill., publish a monthly pamphlet entitled 'Conveying and Transmission,' devoted to the mechanical handling of materials and the transmission of power.

THE PIQUA BLOWER CO. of Piqua, Ohio, is being incorporated under the laws of Ohio with a capital of $50,000. This corporation will take over the interests of the Piqua Foundry & Machine Co., and will make a specialty of the manufacture of positive blowers and gas exhausters as developed by the latter company in the past two years.

THE BARNES-KING DEVELOPMENT CO. will be in the market for all kinds of equipment, including rolls, crushers, belt conveyors, elevators, and mechanical distributors of all kinds; electric hoists, machine drills, mine and mill equipment generally, cyanide equipment and supplies. Manufacturers and business houses interested in this class of equipment should send catalogues and lists to the mine office, at Kendall, Montana.

The miniature catalogues of the A. S. CAMERON STEAM PUMP WORKS, as illustrated above, are printed in English, German, and Spanish. They contain full information as regards types and prices of the Cameron Pumps and can be had on application.

Books Received.

MEXICO'S TREASURE HOUSE, GUANAJUATO, by Percy F. Martin. This is a descriptive account of the mines and mining methods of a famous locality by an English journalist who visited Mexico recently as representative of *The Financial News*. It is a handsome volume of 250 pages, well printed and copiously illustrated. In addition to the interesting descriptions, there is plenty of statistical information. The book is published by The Cheltenham Press, of New York, and is for sale by the MINING AND SCIENTIFIC PRESS at $3.

LEAD SMELTING AND REFINING. Edited by W. R. Ingalls. This is a re-print of articles that has appeared in *The Engineering & Mining Journal*, the *Transactions* of the American Institute of Mining Engineers, together with abstracts of papers presented before other engineering societies. Special attention is given to the desulphurization of galena by what are known as 'lime roasting' processes. The volume comprises 320 pages and contains much useful information gathered from authoritative sources and edited by a skillful hand. It is published by the Hill Publishing Co., New York, and is for sale by the MINING AND SCIENTIFIC PRESS at $3.

GEOLOGY, by T. C. Chamberlin and R. D. Salisbury. Three volumes, making 2,000 pages. This is the most elaborate, most comprehensive, and most modern of all textbooks on geology. It is intended for advanced students and deals with the very latest ideas on a big subject. Vol. I is devoted to Geologic Processes and their Results; Vol. II and III, to Earth History. The authors are acknowledged leaders of scientific thought and widely experienced in field geology, not only in their own country, but in other parts of the world. Therefore this monumental treatise gives not only the very latest information but suggests new lines of thought and scientific development. The geographic portion of the first volume is beautifully illustrated, in a manner quite unlike any other textbook, in fact, all of the volumes are full of excellent diagrams, maps, and half-tones, splendidly printed on heavy glazed paper so as to do them full justice. Therefore, the educational function of the book is facilitated and made attractive to the reader. One drawback may be noted; the inclusion of many theories originating with the authors, and not yet assimilated in accepted science, weakens the book as a textbook, for textbooks should include only ideas that have passed beyond the disputative stage. Some of the authors' views are still on trial, and the prominence given to them is a tactical blunder. On the other hand, as the book is not for mere beginners but for real students, its originality will be appreciated. Despite the vast amount of reading matter provided, there has been decided condensation, so that the volumes are almost encyclopediac in character. The judicial frame of mind, the mastery of their subject, and the moderation of statement of the authors are evident throughout. It is a noble work and does honor to American science. The book is published by Henry Holt & Co., New York, and is for sale by the MINING AND SCIENTIFIC PRESS at $12.

Trade Treatises.

ALLIS-CHALMERS COMPANY issue Bulletin No. 1,501, describing their belted Corliss engines.

WITTE IRON WORKS CO., of Kansas City, Mo., issue an attractive pamphlet devoted to the engines that they manufacture, especially designed to use gas, gasoline, naptha, or distillate.

WESTERN GAS ENGINE CO., of Los Angeles, Cal., has issued an interesting pamphlet on Western Engines for all power purposes, such as this company manufactures. The catalogue gives useful data on gas engines.

SULLIVAN DIAMOND CORE DRILLS is the title of a handsome pamphlet of 160 pages in stiff binding, just issued by the Sullivan Machinery Co., of Chicago. The pamphlet is beautifully illustrated, and contains price lists, together with various data useful to a mine superintendent.

Editorial.

THE REVIVAL of agitation against dredging for gold at Oroville renders timely the article on 'Dredging and Horticulture' by Mr. D'Arcy Weatherbe. It is uncertain whether the anti-debris talk is to be taken as disguised blackmail or merely individualism of an extreme type. We are glad to learn that there is to be a friendly conference between the Dredging Association and the Anti-debris Association, and we hope that good sense will prevail.

A MARKET LETTER from a firm of brokers recently in trouble advertises the fact that the Governor of Nevada is on their directorate and on the board of several mining companies. The circular closes by stating that the Governor is "familiarly known in Nevada as Honest John." This is undoubtedly true in every sense, and it is because Mr. John Sparks is an honorable man that we refer again to that colossal fallacy, namely, that governors, generals, admirals, or any other distinguished citizens are necessarily able to pass upon the value of a mine or to manage its affairs. The plain fact is that such names are used by promoters as a lure and it is the vanity of great men to suppose that their endorsement of an enterprise will make it successful. Into this error the public falls readily, not realizing that the only opinion of a mining undertaking that is worth anything at all is that which is based on experience and technical knowledge.

WE note with pleasure that the scheme to amalgamate the mines of the Copper Range Consolidated with a lot of other properties, has failed. Of the mining companies in the Lake Superior region none is better managed, financially and technically, than the Copper Range Consolidated. The credit is due mainly to Mr. William A. Paine at Boston and Mr. Frederick W. Denton at Houghton. Consolidation of holdings is well enough when it means economy of administration, but this idea of mere bigness is a blunder. Once you work with a unit of proper size, there is no particular gain in enlarging it, and the Copper Range Consolidated includes three large mines, with their respective mills, a railroad, half interest in a smelter, and other property quite sufficient to keep even the best administration fully employed.

The subject invites further remark. The amalgamation, using the word in more than its literal sense, of mining companies, means the control of immense interests by the group of men associated with the Amalgamated Copper Company. Now, Mr. Thomas F. Cole and his partner, Mr. John D. Ryan, whose names appear with tiresome iteration in all the news-letters from the mining centres of the country, are men of unusual ability, likely enough, but it is absurd to suppose that they can apply that ability usefully among such a multiplicity of engage-

ments. The fact is they are engaged in gambling on a large scale and they have a financial backing strong enough to enable them to form all these immense consolidations. In the end either they will bite off more than they can comfortably assimilate, and we shall have a disastrous collapse, or they will become part of the financial tyranny represented by the Standard Oil group. For the technical men, the mining engineers and metallurgists, of the Amalgamated Company, we have the highest respect—no enterprise is served by greater scientific ability—but of the blind-pool type of finance that the Amalgamated represents there can be only one opinion. It stands for corruption on a large scale, for colossal gambling with the funds of corportions, and for the irresponsible type of finance represented by Mr. E. H. Harriman and others whose training is that of the Wall Street plunger.

Gratuitous Advice.

By a recent judicial decision a London newspaper has been held responsible for giving wrong advice to a reader who asked for guidance in share speculation and a judgment for the full extent of his loss, namely $7,000, has been entered by the Lord Chief Justice against the publisher, C. A. Pearson. This episode is not without a moral and we hope it will serve as a precedent. In the first place, people should not give advice gratuitously and the public should not ask for it on such terms. Two wrongs cannot make a right, but the publisher is the more erring of the two because he pretends to have special knowledge, sufficient to make his advice valuable. This is rarely the case, for, as we have said again and again, no information on a mine is worth anything that is based on hearsay, and newspapers retain only reporters—not mining engineers—to collect the data they use. With a technical periodical it is different, and that is exactly why the respectable technical press does not give advice on stocks. It is not the province of the editor to give information that should be obtained in the usual way, by engaging the services of a professional man. It is not necessary always to send him to the mine at a big expense; often he knows enough about the locality or the conditions surrounding an enterprise to give a bit of good advice, and in such cases a small fee will meet the case. On the other hand, this writing to papers for advice on stocks tends to breed a corrupt journalism that does great harm, to simple people—and in mining the public in general is simplicity itself. The habit of expecting something for nothing, of asking financial advice from newspapers, has caused a multitude of parasitic sheets to spring up all over the country, after the model of the gutter press of London, where this sort of thing is done on a large scale all the time. Mining companies that advertise in such papers get kindly mention and warm puffs; those that do not, receive cold neglect and sometimes vicious criticism. A simple-minded speculator who writes to ask concerning the value of his stock and the prospects of the mine it represents will receive a reply colored rosy or blue according to the exact financial relation between the publisher and the mining company. We are getting much of this sort of thing in America now; formerly it was uncommon. The warm air of stock gambling has forced a growth of pseudo-journalism and it will flourish as long as a large portion of the public is speculating in cheap stocks. The postal authorities can do something to stop it, but the worst forms of the practice avoid illegality and are impossible to punish. In the meanwhile we would like to see a test case brought to trial on this side, similar to that just decided at London.

State Mining Legislation.

An important mining bill is before the Legislature of the State of California. We refer to Senate Bill No. 55. There is nothing objectionable in the measure, except the requirements as to recording with the district recorders. The county recorder's office is the proper place, and the necessity for duplicating the record is not only inconvenient, but a nuisance without any compensating feature. Under the proposed act the locator has over three months to complete his record; this certainly gives ample time for him to record his notice, even if the county seat is far removed from the place of his location. All transfers, agreements, bonds, mortgages, and other instruments affecting title to mining claims must be filed in the county recorder's office. There appears, therefore, to be no necessity for a district recorder with whom nothing but notices of location could, in the nature of things, be recorded. If the State proposes to pass legislation on the general lines outlined in this bill, we can see no reason for perpetuating the mining district. The bill covers fully the field which, in the absence of such legislation, might, to some extent at least, be regulated by local district rules. In the enactment of such legislation we think the district recorder should be eliminated.

The act is framed in the main on the Nevada statute. Experience has shown that that law works satisfactorily, with the exception of the requirement for recording in two places. At the present time California has no law upon the subjects covered by the bill. We should have a law at least defining the manner of making locations, performance of location work, providing for a proper record of the claim, and the marking of the boundaries, making certificates of location *prima facie* evidence of performance of certain acts, and enabling locators to start out in life with the semblance of a paper title in the form of a statutory notice of location properly recorded. Sections 12 and 13 refer to the property rights conveyed by mining claims; these clauses are useless. This is not a subject upon which the State is permitted to legislate The nature and extent of the property right acquired by location is determined by the Federal law. These two sections, however, may be said to be harmless, as declaratory of the Federal law. Section 16 is subject to the same criticism and comment.

In its main features the measure is a good one. Among the States producing precious metals and under the Public Land regulations, California is the only one that has no legislation on the subjects dealt with in the bill. The mining interests of the State will not suffer if the legislature follows precedents that seem to work well in other jurisdictions.

By the Way.

In a recent issue of *The Times*, New York, there is an article by Mr. Daniel Guggenheim, dealing with the metal markets. He says:

The business of the world has been seriously hampered during the latter half of the year 1906 by a lack of sufficient capital. In other words, the production of the money metals, on which all currency is based, has not kept pace with the increasing demands of the world. These demands have been due to plentiful crop, large consumption due to prosperity, and enhancing values.

To what extent these enhanced values have been produced by an increased production of gold is a question of great interest, but one which cannot, unfortunately, be settled dogmatically. As a matter of fact, the production of gold has increased during the past ten years by leaps and bounds. During the '80s the production of gold in the world ran as low as about $90,000,000. For the year 1905 the Director of the Mint estimates the value of the gold production of the world at $375,000,000, and during the year 1906 the production has increased doubtless more than during any preceding year. This has notably been the case in South Africa and in the United States. Alaska has for years been a growing factor in the gold production of the world, and recent developments there seem to indicate, on account of the influx of large amounts of capital which are necessary for the development of such gold-fields as are there found, that the year 1907 will show a notable increase. Notwithstanding these millions of new capital, the world seems to be crying for more, and the need is apparently as great today as during any previous period of the past. With the wealth of the world increasing, the consumption of gold in the arts is constantly augmented.

The prosperity of the countries usually referred to as 'silver countries,' but whose accumulated capital is now being held in gold, has made during the past year and is likely to make during the years to come, a very decided drain upon the gold resources of the world. South America, Japan, India, and even Mexico, are receiving and hoarding gold by the millions, and the central gold market of the world, London, has been denuded of its capital to such an extent that the great Bank of England has been obliged to call upon the Bank of France in its urgent need, and is now demanding that the gold reserve of the banks of London shall be materially increased. The recovery of South Africa from the effects of the Boer war; the great discoveries of gold in Nevada; the influx of capital and more modern mining appliances into Alaska, all point to a materially increased production of gold for the year 1907. But doubtless the scramble for the yellow metal will go on as fiercely as in the past.

The position of silver in the world is unique. As a production it has shown no increase for the past ten years. The report of the Director of the Mint for the year 1905 conforms almost exactly to the production of the year 1896, namely, 157,000,000 ounces. During this period of ten years the price of silver in the New York market has been as low as 46 cents, and at the close of the year 1906 it was selling above 70 cents, or an increased price of more than 50%, yet the reports of the Director of the Mint show a decline in production for the year 1905, as compared with the preceding year, and there seems every reason to believe that no increase in the production of silver has taken place during the year 1906.

As a matter of fact, silver is produced largely as a by-product in connection with the production of copper and lead. Its production, therefore, is not based upon its value. Furthermore, and peculiarly, the consumption of silver is also not regulated except to a very minor extent by its value, at least within known ranges. The United States, needing to buy silver to satisfy the demands of the people for subsidiary currency, the silver will be purchased, since the Government coins it at the rate of $1.38 per ounce. If the silver can be purchased at 69 cents, the Government issues it at double its cost, and should the cost of the metal be one dollar per ounce, the Government would purchase the same quantity, but would make a profit of 38% instead of 100% in coining. This is similarly the case with most of the coinages of the world. The consumption of silver in the arts is constantly increasing with the increased number of inhabitants and the increased wealth of the world. Doubtless an increased price, if considerable, would make an appreciable difference in the consumption of silver in the arts, but as compared with the total consumption this would be insignificant.

For many years there has been no accumulation of silver. Consumption has at least been equal to production at all times, and for several years it has been considerably in excess of the amount produced yearly from the mines of the world. The additional amounts consumed have been obtained from various sources, notably, the accumulation in the treasury of the United States at Washington; the accumulation at Berlin, caused by the demonetization of silver in Germany in 1869, and the silver reserve held against circulation in Mexico, Japan, and various South American countries. Apparently these various supplies have been nearly, if not quite, exhausted, and, unless some new, notable discovery of silver is made, the demand for silver during the year 1907 is likely to far exceed the supply. India always has consumed on the average about 50% of the world's production of silver.

Several years since it was predicted that aluminum would certainly take the place of copper, should its price materially exceed 15 cents per pound. This now proves to have been a delusion, as, with the constantly increasing production, the price has reached 24 cents per pound, and is being vigorously pushed higher. The production of copper is constantly increasing, but as yet the increase does not equal the increased demand. The large producing mines which have been in existence for years cannot materially increase their production. Economic working requires full production at all times without regard to price. The only hope for increased production lies in the discovery and development of new properties. The development of such mines and the construction of the necessary reduction works require years of time and millions of money. The wonderful discoveries of copper ore in Nevada were made three years ago. Several properties which will be large producers in time have been in constant process of development, and reduction works are now planned, but it will be some time yet before any considerable production of fine copper is derived from this source.

Reports of prospectors as to copper mines in Alaska have for years been so highly colored as to seem like fairy tales. Reliable engineers, however, have reported this past summer on several copper properties which indicate that in time, but probably not in less than three years, Alaska will become a considerable producer of copper. Similarly the copper mines of the Congo await development and the construction of reduction works and railroads, which will delay the receipt of copper from this source doubtless for five years or more.

From the above it will be seen that the increase in the production of copper is bound to be gradual, and may not more than keep pace with the increasing demands of the world.

Special Correspondence.

Johannesburg, Transvaal.

Politics.—Publication of Pamphlets.—The New Constitution.—Eight-Hour Day.—Outlook Uncertain.

That political party known as the Progressive is becoming rather aggressive. Of late several trenchant pamphlets dealing with the situation have appeared, and one is reminded of a big political fight in England, where pamphleteering plays so important a part. The labor question is the principal topic of these papers. They ably refute the affirmations often made by irresponsible aspirants for political honors, namely, that there is ample native labor in South Africa for all requirements, and that the introduction of Chinese was unnecessary. In one of the pamphlets it is clearly shown that commissions appointed to investigate the native labor supply, came to the conclusion that South Africa could not supply all needs. There has been an incessant cry of shortness of labor in this country for the last fifteen years. One of the most interesting pamphlets is headed 'E. P. Solomon's Diary.' This gentleman is the leader of the National Association (which their opponents have christened the National Asses) and is violently anti-Chinese. In this pamphlet it is clearly shown how the mines will close down as soon as the Chinese are repatriated. On nearly every mine, and in most of the towns, the different parties have held meetings. It looks as if the Progressive or pro-Chinese party were gaining the confidence of the voters of the Witwatersrand. There seems to be serious dissension in the ranks of the National Association, and many people predict its disruption.

The publishing of the Letters Patent of the new constitution granted by the Liberal Government has not been hailed with satisfaction by the British population, while the Boers are delighted with the document. There is no doubt that it is highly favorable to the Boers. From reading the constitution one would think that Chinese labor on the Rand was doomed. It is stated that the coolies must be sent away one year from the sitting of the first parliament, or sooner, if the first parliament so desires. Parliament will meet about July, 1907, so that if the law regarding Chinese is carried out, there should be no coolies for the mines in July, 1908. This is a very serious outlook, for it practically means that a number of mines well be forced to close down. No one acquainted with the situation expects to find sufficient Kaffirs to take the place of the Chinamen. There is only one hope for the retention of the coolies, and that is the success of the Progressive party.

If the majority in the first parliament vote in favor of Chinese labor, it is believed that the Home Government will not interfere in a subject of such vital importance. The Progressive party has a good fighting chance of winning the elections, hence the aggressive tactics they are adopting. They will put up a good fight.

As a bait for the labor vote, most of the parties are putting the eight-hour day as a plank in their platform. One party is very much against the running of the railroads for revenue, but if the Government is not supplied with money through the railroads, it is difficult to see where the revenue to run the country will come from. Another favorite plank is the reduction of the expensive Government service which now exists. Every one is preaching economy.

Speculative ventures still appeal to the public here, and in spite of the scarcity of money, several new mining schemes that have come out lately are eagerly bought up. Very little business is done in proved mines. One notices that at present prices several mines on the Rand are well worth having. But if the Chinese depart, these mines will not be worth much. It is a big risk to buy the shares.

City of Mexico.

The Boleo Copper Co.—Large Operations.—Pacific Copper Co.—Activity in Chihuahua.—Quebradillas Mill.—Almoloya District.—The Batopilas.—Production Maintained.—Encinillas Smelter.—Dividend from the Amparo Mines.—Boom in Nuevo Leon.—General Activity.

The Boleo Copper Co., the French concern in which the Rothschilds are principally interested, and which owns the smelter and mines at Santa Rosalia, in Lower California, is in a prosperous condition. During the year 1906, the smelter treated 302,500 tons of ore; the product, of a value of about $5,000,000, was shipped to Europe. All coke for the smelter is imported direct from Cardiff. At present the Boleo company is paying employees $160,000 monthly. At the Purgatorio group of mines the monthly payroll is $45,000; at the Providencia group, $35,000; and at the Soledad group, $32,000. The smelter employees draw $17,000 per month, and other employees draw $31,000. The company controls the town and port of Santa Rosalia. The stores, meat market, and bakery are owned by the company, and a theatre and public bath are maintained for the benefit of the employees. Ernest Michot, the general manager, will soon visit the Inguaran copper mines, in the State of Michoacan, which is also owned by the Boleo company. It is stated that a railroad will be built from the Inguaran mines to the Pacific port of Zihuantanejo.

The Pacific Copper Co. has shipped a large amount of machinery to its property at La Union, in Guerrero. H. L. Swain is the consulting engineer. The company has a capital of $10,000,000, and controls about 1,000 pertenencias of copper land, situated about 30 miles east of the port of Zihuantanejo, and not far distant from the Inguaran mines of the Boleo company.

The prospects of an active year in mining in Chihuahua are good. During the past two months C. M. Schwab and W. C. Greene have invested fully $2,000,000 in Chihuahua mines; the American Smelting & Refining Co. is building a great smelter at Chihuahua; at Parral, the Parral Power & Reduction Co. has a large plant from which it expects to distribute power for mining purposes; the Greene Gold-Silver Co. has built the best wagon-road in Mexico from Temosachic, on the Chihuahua & Pacific railroad, to Ocampo.——The Mexican Gold Fields Co. expects to start dredging operations during the year on its placer ground known as the Santo Domingo placers, on the Conchas river. G. H. Lehr, of Chicago, the president of the company, is here with a California dredgerman, making a study of the ground.——The work on the new 80-stamp mill at the Quebradillas mine in the Parral district is progressing rapidly, and the mill will be in operation within six months.——The Almoloya Mining Co., composed of Monterey people, shipped 4,000 tons of high-grade zinc ore during 1906. The ore is calamine. The company expects soon to strike silver-lead and copper ores similar to the Cigarrero mine adjoining.

The Batopilas Mining Co. operates under a concession from the Mexican Government, covering 61 square miles of mineralized territory in Chihuahua. This company is capitalized at $9,000,000, and, during its existence, it has shipped over $19,000,000 in silver bars. It has two mills for the reduction of its ores, one of 100 stamps for treating low-grade stuff and one with 25 stamps for high-grade and native silver ore. These mills are run by water-power, the water being conducted through an

aqueduct of solid masonry, built along the mountain-side for a distance of two miles. An adit nearly two miles in length runs through the property, cutting several bonanza veins. Haulage in this adit is by gasoline locomotives. The first shipment in January was 77 bars of silver bullion, worth $111,000.——At Ojo Caliente, Jas. Gasson has a shaft down 400 ft. Some rich silver ore has been found in this camp.——More stacks are being erected at the Encinillas smelter at Santa Rosalia, and the new management is contracting for ore. The plant has been going to start for some time, but complications have always prevented. The Encinillas Mines Co., Ltd., is owned principally in France. Hundreds of thousands of dollars have been spent, with no return. The company pumps have been installed and the work of unwatering the old mines has begun. This group comprises the San Vicente, Dolores, Santiago, and San Pablo properties, all of which have been under water since 1898. The Dolores shaft is 375 ft. deep, and all the shafts are connected at depth. Daniel Milmo and M. T. Cogle, of Loredo, are the principal owners.——The Santa Maria and Anexas properties are shipping six cars of zinc-blende per month. The Santa Maria shaft is down 240 ft.——Adjoining these Garnett properties are the eight properties leased by the Santos Zinc Co., and in turn leased by them to the American Metal Co. These properties are producing about 400 tons per month.——The most important mine in the Sabinas Hidalgo district is

Sketch Map of Mexico.

has no ore of its own, and the smelter will have to depend upon custom work.

The Amparo Mining Co., of Philadelphia, which owns the Santo Domingo, San Juan, Union, and other mines in the Etzatlan district, in Jalisco, has declared its first dividend of 3%. This company was organized with a capitalization of $3,000,000, but $1,000,000 of treasury stock was retired last year. In 1906 the mine produced 863,850 oz. silver and 7,717 oz. gold. The foundations for the company's new 40-stamp mill, in Magistral cañon, are completed.——The Ayutla Mining Co., of Jalisco, has resumed operations. The local stockholders are A. W. Geist, E. G. Coffman, and A. H. Brewer, and Boston capital has become interested with them. The company owns the San Felipe, Zapatero y Anexas, and Vesuvio properties, and the surface holdings amount to about 60 pertenencias. About 3,000 ft. of development work has been done, and the ore runs about 10% copper, with good gold and silver values.

The Sabinas Hidalgo and Vallecillos districts in Nuevo Leon are reported to be experiencing a great boom, in spite of the scarcity of laborers. The Vallecillos camp is producing from 800 to 1,000 tons per month, including lead-silver and zinc ores. The Vallecillos company has the best equipped outfit in camp, and has just finished the work of separating and concentrating the old dumps at its mines, a work which has taken five years. Large the Cruz del Aire. This property has just paid its fifteenth monthly dividend of $5 per share on 1,500 shares. The output is about 400 tons per month, including lead and zinc ores.

Toronto, Canada.

Report of the Geological Survey.—Interesting Account.—Coal in the Northwest.—Valuable Discoveries.—Gold on the Watson and Wheaton Rivers.—Occurrence of Tellurides.—The Klondike Gravels.—Vast Deposits Still Available.—The Tulameen River.—Rossland.—Report by Brock.—Extension of Cobalt Region.—Insufficient Funds for Survey Work.

The summary report of the Geological Survey of Canada for 1906, which has just been issued, gives an interesting resume of mining conditions in Canada, and the results of the investigations made by the exploration parties sent out by the Survey during the year, some of which are of great significance. Brief reference has already been made to some of the more important features of the volume, especially to the opinion expressed by the Director, Mr. A. P. Low, as to the situation at Cobalt. The reports of some of the field parties engaged in researches in less known and more remote portions of the country, contain a mass of information, many details of which have an important bearing upon the mining and metallurgical industries.

In accordance with the policy of the Survey the field work was mainly confined to economic subjects, the investigations being carried on in mining regions along the proposed routes of new railways. No parties were sent into the less accessible districts to the far North, the idea being to advance gradually with exploratory work extending it systematically, northward. In all, twenty-four parties were sent out. The principal interest attaches to the work on the Yukon, in British Columbia, and in Alberta. The leading discovery of the year was that effected by the party in charge of D. B. Dowling, engaged in mapping the Rocky Mountains coal districts, by which the existence of a large coal-field extending northward from the Saskatchewan to the Brazean river was brought to light. Mr. Dowling's report states that these measures are raised much higher than those of the field south of the Saskatchewan and that all the formation can be got at either on the western slopes of the Bighorn range or in the gorge of Bighorn creek. Samples from a 16-ft. seam gave the following analysis:

Moisture, 2.50; volatile combustible matter, 27.10; fixed carbon, 64, and ash, 6.40; the fuel ratio, volatile to fixed carbon, being 2.36.

This is a good steam coal and probably of the best grade for coke. In view of its proximity to the transcontinental railway and of the scarcity of high-grade coals in the country to the east, this discovery is of great importance.

A considerable portion of the report of D. D. Cairnes, on the Yukon south of Whitehorse, is devoted to the anthracite and bituminous coal deposits of that region. Several seams of anthracite are located in an area known as Whitehorse, outcrop occurring 12 or 14 miles southwest from Dugdale Siding. A tunnel about 60 ft. long has been run on one seam and a few open-cuts made, otherwise the coal is entirely undeveloped. The general strike of the measures, which are quite regular, was traced for over 12 miles. Seams measured were 9 ft. 8 in., 10 ft. 4 in., and 2 ft., 6 in., respectively. Surface samples run high in ash but at a lower depth the ash will be considerably less. Its proximity to the Whitehorse copper deposits and the gold areas on the Watson and Wheaton rivers should render this coal valuable. The Tantalus mine on the west side of the Lewes river about 190 miles down from Whitehorse and about half way to Dawson, yields a bituminous coal giving an average of about 75% firm coherent coke. As the coal outcrops on the river banks it is well situated for economic working. The season's shipments were estimated at 7,000 tons. Two tunnels were in about 700 ft. in October. These measures are quite regular and can be traced for over 20 miles down the Nordenskiold river to the south and 10 miles to the north, showing an enormous amount of coal in the district. The same measures outcrop at Tantalus butte, across the river from the Tantalus mine. A considerable amount of coal has been shipped from Five Fingers mine eight miles north of the Tantalus, but the workings being dangerously situated, have been abandoned.

Mr. Cairnes examined the Watson and Wheaton River properties, where quartz carrying free gold and telluride minerals was found last summer. Within 90 days from the location of the first claim, the Gold Reef at Gold Hill, on June 25, 700 claims had been staked. Outcrops of quartz closely resembling each other are seen in almost straight lines at short intervals with the same general strike from the Watson river to within about 8 or 10 miles south of the Wheaton river, a distance of nearly 20 miles, and though most of the veins found were in this narrow belt about two miles wide, some deposits of pure stibnite and other minerals were discovered by the Survey party at a considerable distance to the west. In addition to occasional assays running as high as $300 a number of assays of from $20 to $60 were obtained in this district. With the exception of a small amount of work done on the Gold Reef, no attempt has been made to test the veins as yet. Taking into consideration the large quantity of mineralized quartz and the small amount of prospecting done, the results appear encouraging. On the Windy Arm properties a great deal has been accomplished with good results. A number of properties were worked continuously last winter and through the summer. The Pueblo copper property west of Whitehorse presents an enormous surface showing of copper ore.

R. G. McConnell and his party were engaged in measuring the volume and estimating the values of the high-level gravels in the Klondike district, but their work was not completed in time for the results to be embodied in the report. It is stated, however, that with 25 miles of proved dredging ground in the valley flats and tens of millions of cubic yards of workable gravels on the benches, profitable mining on the Klondike is assured for many years.

The work of delimiting the coal and copper areas of the Telkwa valley, in British Columbia, was assigned to W. W. Leach, who reported that as far as coal was concerned the task was one of extreme difficulty owing to the faulting and folding of the measures. It will require close prospecting before the extent of the coal areas is proved. Detailed information is furnished respecting the copper-bearing deposits of Hunter basin and other localities where claims have been staked. Charles Camsell, who was detailed for surveying work in the Similkameen district reports great activity in mining, laying much stress on large areas of low-grade ore. For many years the placers of the Tulameen river and its tributaries below Champion creek have been profitably worked for gold and platinum. These placers have been gradually exhausted and from being the principal producer of platinum on the North American continent the Tulameen river now supplies only an annual output of 30 or 40 oz. of that metal. With the revival of mining activity the production of lode-mining will probably be greater than the output during the best days of the placer miner.

A detailed report of operations at Rossland is presented by R. W. Brock. He states that during the past year development work has been pushed more vigorously than formerly, with the result that more ore is in sight in each of the mines than has been for a good many years. An examination was made of Franklin camp on the North Fork of the Kettle river, where many claims have been taken up. Mr. Brock reported that as none of the claims were past the prospect stage, and none of the workings had attained depth, it could not be definitely stated that another camp had been added to the British Columbia list, though there seemed to be a reasonable prospect that some of the properties might develop into mines.

The investigations of A. E. Barlow, who was engaged in tracing eastward into the Province of Quebec the formations containing the silver-cobalt-nickel ores of Cobalt had little practical result. The area examined covered five townships and an unsurveyed tract immediately east of Lake Temiskaming. It was found that while the formation was geologically identical with that of the Cobalt region, it is overlaid with clay strata and the quartzite and conglomerate of the Upper Huronian. The outcrops of the Lower Huronian conglomerate and slate are small and often widely separated, giving only a limited field for prospecting. No mineral finds of importance were made.

W. H. Collins reported the western portion of country along the Transcontinental Railway route as auriferous

and iron-bearing and worth the attention of prospectors. A strip along the line of the same railway eastward from Lake Abitibi was examined by W. J. Wilson who found molybdenite on an island in Seals' Home lake, and copper pyrite on the Harricanaw river and other points in Quebec Province.

Mr. Low in dealing with the season's work points out the disabilities under which the Survey labors on account of the inadequate means at its disposal. While the value of the mineral production is over six times as great as it was 20 years ago, the appropriations for the Survey and the Mines Branch of the Interior Department have only increased during this period from $115,053 to $173,553. The remarkable expansion of the Canadian mining industry and the vastly larger area to be covered seem to call for greater liberality to this useful branch of the public service.

Butte, Montana.

Small Copper Production in January.—A Local Exchange.—Smelter Smoke.—Gold From the Cable.—Prospecting in the Main Range. Exploratory Work in the Badger State and Gagnon Mines.—Butte & Superior.—Montana Consolidated.—A Lewisohn Enterprise. New Incorporations.

The January copper production will be the smallest of any month in nearly two years. The ordinary output of the Butte district was reduced 15 or 20% by the shortage of cars and fuel, and the cold weather. The extremely cold weather, which continued for more than two weeks, blockaded the traffic on the railroads and also froze the ore on the cars, so that it could not be unloaded after being transported from the mines to the smelter. The inability of the railroads to provide coal also compelled some of the mines and the Clark smelter in Butte to suspend operations.

The Butte Mining Exchange was opened last week and is now running successfully. The Exchange is rapidly establishing a value for many Butte stocks that heretofore were variously quoted and held at high figures by local brokers. The prices on stocks have averaged about as follows: Butte Copper, 94@95c.; East Butte Extension, 30@35c.; Butte & Milwaukee, 60@65c.; Amazon-Butte, $1@1.20; Butte Copper Exploration, $4.50@5; Butte & London, $2.50@2.75; Colusa-Leonard Extension, $2.50; Butte-Montana, 77@80c.; Butte & Bacorn, 45@46c.; Pittsburgh & Montana, $4.50@5; Reins, $1.15@1.20; Bullwhacker, $1.35@1.45; Barnes-King, $5@5.25; Cable Consolidated, 55@56c.; Snowstorm, $2.77@2.85; Stewart, $1.75@2; Raven, $1.05@1.15.

The significant fact was brought out a few days ago at the hearing on the alleged damage done by the smoke from the Washoe smelter, that President Roosevelt has taken an indirect interest in the matter. From the testimony of W. G. Weigle, a government timber inspector in the service of the Forestry Bureau of the Department of Agriculture, it appeared that the ranchers of the Deer Lodge valley appealed to the President to have a Government official look over the valley and determine the conditions as they apply to the timber growth on government land. The President directed the agricultural department to have the matter attended to, and the inspector was sent to Montana. He has been at work since last September, and has been summoned as a witness in behalf of the ranchers, who are seeking to shut down the big Washoe smelter. Thus President Roosevelt is assisting the ranchers in the prosecution of the Amalgamated company and the smelter. The inspector testified that he found the trees dying within a radius of several miles around the smelter, due to the smelter fume. He said he found thousands of trees that died last summer. This evidence of the Government official is recognized as very important to the ranchers.

A bar of gold worth $6,000 was brought from the mill of the Cable Consolidated Co. a few days ago and shipped to the United States assay office at Helena. The company is operating its 30-stamp mill, and in addition to treating a large amount of gold ore, it is making regular shipments of copper ore from the mine to the Washoe smelter.—The Butte Copper Exploration Co. has put in operation a large pump at the 1,000-ft. station of the Six O'Clock mine, and is now driving the cross-cut north as fast as possible. The face of the cross-cut is now about 520 ft. from the shaft. The company has purchased the Water Witch, north of the Six O'Clock, and is driving the cross-cut toward that property.

After many years mining men have started to explore the veins on the apex of the mountain range east of Butte. At a point 4½ miles east of Butte prospectors have developed an excellent showing of copper ore, and a company called the Butte-Continental has been organized to develop the ground more extensively. On one of the claims there is a vertical shaft 60 ft. deep near the foot-wall in a quartz-porphyry formation, while near the hanging wall another vertical shaft has been sunk to a depth of 108 ft., from which 300 ft. of cross-cuts have been run at the bottom. Between a depth of 30 and 50 ft. the shaft penetrated ore five feet wide, assaying at first 3% copper, but before the vein finally left the shaft on its southerly dip samples across the entire width assayed 8% copper, 12 oz. silver, and 40c. in gold.

Work on the Badger State shaft, which is being sunk by the Boston & Montana Co., is already down 125 ft. and the bottom is in granite. The shaft has three large compartments, and will be taken to a depth of 1,800 ft. before any cross-cutting work is done. The company has been satisfied that the big veins of the North Butte Co. pass through the Badger State. At present only a small sinking engine is in use, but as soon as the weather will permit the foundation for a large plant will be laid.—At the Gagnon mine of the Trenton Co. the shaft has been completed to a depth of 2,100 ft., and at that point a station is being cut. As soon as that is completed a cross-cut will be driven to the vein, which is near the shaft. The vein is not the Gagnon vein, but one that has dipped into the Gagnon ground from the Original It was found by the Gagnon at the 2,000-ft. level, and it was estimated that another 100 ft. in depth would bring it entirely within the Gagnon lines.—The Butte & Superior Copper Co. has purchased the Enterprise and Laura claims and has added them to the Blackrock group. The main working shaft is on the Blackrock, and it has reached a depth of about 570 ft. At the 500 some 3% copper ore was found, and the shaft will be taken to a depth of 800 ft. before any cross-cutting will be done. Captain A. B. Wolvin, president of the Zenith Iron Co., and other Duluth men of prominence, have secured control of the Butte & Superior Co., and Mr. Wolvin has been elected president.

The Montana Consolidated Mining Co. has been organized with a capitalization of $2,500,000 by Lewisohn interests to take over a lot of options on mining properties that have been held by the General Development Co. The latter has for six months been engaged in exploring the Brundy group of claims southeast of the city of Butte, and also owns the Granite Mountain claim, adjoining the Jessie of the North Butte Co. The Montana Consolidated will also take over the property of the South Butte, the latter being the mining corporation of the Great Northern Railway Co. that owns about 45 acres of mineral ground along the right-of-way of the Great Northern in South Butte.—Still another company organized during

the past week is the North Butte Summit Copper Mining Co., its purpose being to work seven claims situated five miles northeast of Butte in the Lost Child district. The incorporators are all Butte men. The company will drive an adit to cut the lode at a depth of 500 ft. The lode is a contact between porphyry and granite, showing fully 300 ft. wide on one of the claims. In sinking a shaft ore was found at a depth of 22 ft. that assayed 1.3% copper. This property is in the mountains and timber is plentiful.—— The Butte & Summit Valley Copper Co. is making rapid headway in the work of diamond-drilling, making about 30 ft. per day with the drill. The company owns 67 acres of mineral land near the Ida-Montana Co. It has two shafts, each 250 ft. deep, from the bottom of one of which the diamond-drilling is done.

London.

Gold Mining in Siberia.—Slump in Stocks.—Defective Titles.—Another Nerchinsk Company.—Report of A. L. Pearse.—Good News From Spassky.—Cornish Mining.—Vigorous Operations Promised.

Evidence is accumulating to prove that the Russian Empire offers both scope and safe opportunity for the remunerative employment of capital in mining enterprise. But nowhere is it more necessary to exercise discrimination and judgment as to the local conditions under which the operations can be conducted. It is also useful to bear in mind that in dealing with properties requiring development and the installation of efficient machinery and plant a considerable time must be allowed before profits available for dividends can be expected. For these and other reasons, such, for instance, as overcapitalization, readers of my correspondence will perhaps be less surprised at the severe slump which has overtaken the stocks of Siberian Proprietary and of its two offsprings, Orsk Goldfields and Troitzk Goldfields, than some operators in London who have gaily bought these shares on each upward move to the giddy height from which they have fallen during the last few days. In the words of a City editor: "It is years since any market in the Stock Exchange became so panic-stricken as did the Siberian mining market yesterday. Amid a scene of the wildest excitement and confusion the shares of the Siberian Proprietary Mines, Ltd., which quite recently were among the most popular of Stock Exchange and society gambles, fell enormously, taking down the shares of the two other companies of the group—Troitzk and Orsk—with them. The losses among some speculators must be exceedingly heavy. Such was the extent of the fall that whereas Siberian Proprietary shares opened at 14¾ for the one pound share, and 'made up' for the settlement at 14 during the morning, they closed no higher than 9¾, after having been down to 9½. Orsk shares fell from 2¼ almost to 1½, and Troitzk shares from 1⅜ to little over 1. The promoting power behind the group is the H. O. Syndicate, which derives its name from Mr. Heyman Orkin, who is managing director of each of the companies. The group of companies has shown much better results in company-mongering than in gold-getting, and attention has been drawn to the manner in which shares have been passed on to people in high society and their names used to induce others to come in." One explanation of the *debacle* relates to these companies' titles, which are said to be incomplete. On the other hand "capable and wealthy insiders" are supposed to have withdrawn their support from the market. In the hurly-burly, little notice is given to the absence of profitable mining results—the only "support" which is really essential to the continued stability of prices. In the perplexing circumstances now existing with regard to the companies in question the return of Mr. Orkin, now on his way from St. Petersburg, is eagerly awaited. It is thought he will avail himself of an early opportunity to meet the shareholders and re-assure them on the points now so fiercely discussed in the financial press. On the subject of Siberian titles it is interesting to note what the solicitors of the Proprietary Company have to say. From a letter these gentlemen have sent to the papers, it appears that so far as foreign companies are concerned, it is quite clear that, on obtaining the necessary license from the Russian Government, they are entitled to hold and deal in both movable and immovable property, including mining and mining rights, to the extent to which they are authorized by their articles of association. The obtaining of this license is purely a question of formality, provided the Russian Government is satisfied that the company is *bona fide*, but some time is required before the necessary formalities can be concluded. Pending the necessary license being obtained, foreign companies are entitled to, and do in effect carry on, business, and hold property both movable and immovable through the medium and in the name of attorneys, whether foreigners or Russian subjects, the only requirement being that such attorneys should act in their own name and have the necessary status of merchants of the First Class Guild. This statement, however, still leaves the stockholders in question in doubt as to whether, in their case, licenses have been granted by the Russian Government or not.

Having regard to the present aspect of the market it cannot be said that the word 'Siberia,' which heads the prospectus of Nerchinsk Options, Ltd., is calculated to be very helpful, although this flotation has been taken in hand by, and is an offshoot of, Nerchinsk Gold Co., Ltd., concerning which no doubt whatever is suggested as to titles. The area selected for the 'options' company is situate in the eastern part of the Nerchinsk mining district of Siberia, in the neighborhood of the property of the Kluchi Gold Mines. The company does not propose itself to work any of the properties that it may acquire, but to promote other companies for these purposes, in conjunction with the Nerchinsk Gold Mines. Prospecting work has already been done by the Nerchinsk Gold Company on the area included in the license to prospect, under the superintendence of that company's consulting engineers (Pearse, Kingston & Browne), and according to a report of Mr. A. L. Pearse on this area, dated November 21, 1903, the following are some of the discoveries: "Rich quartz float found above the line of some of the richest placers on the concession. The Eisenhut lode was found by costean trench on the west side of the Kostremyka creek. Its outcrop is 10 ft. wide, of gray quartz, and worth half an ounce per ton. The Twin is an outcrop of quartz 3 ft. wide, similar to the Eisenhut, farther up the hill. The discovery shaft is down 30 ft. on the hanging-wall side, and exposes 4 ft. of the lode-matter. The present value is half an ounce per ton. The lode is nearly vertical. The Growler is a lode 3 to 7 ft. wide, two miles up the stream from Koudechi. A shaft is sunk 20 ft. on the hanging wall. Its direction is N. 30° W. It is a promising-looking lode of white quartz, carrying pyrites, chalcopyrite, and a little lead. Two assays made of samples from here gave 11 dwt. and 5 dwt., respectively." It would appear from these particulars that further developments are necessary before these properties can be ready for offer to the public.

Some noteworthy particulars are available from the Spassky copper mine. In a recent cable Mr. Nelson Fell reports: "Returned tonight from Yuspenssky; development of last two months produced surprising results; believe no

exaggeration to say that reserves of ore are doubled." It is stated that the latest previous estimates of reserves were made by the consulting engineers in November last on the basis of the then price of copper, and were as follows: (a) Assured ore down to the 350-ft. level, 88,676 tons, containing 15,338 tons of recoverable metal estimated to yield a net profit of £80 per ton, or £1,227,040; (b) reasonably assured ore down to a further 100 ft. (of which 20 ft. had been sunk), estimated at a further 96,833 tons, containing 16,745 tons of recoverable metal, of an estimated net profit of £1,339,600. The total net profit value of ore actually or reasonably assured was thus calculated in November last at £2,566,640. When this company's establishment and installations (which are on a large and costly scale) are complete, those 'in the know' predict the commencement of a brilliant and lasting future for the mine.

Salt Lake, Utah.

Fuel Famine.—Better Railroad Facilities for Bingham.—Enlarging the Mills.—Railroad into Deep Creek.—Annual Report of Utah Copper.—New Mill at Garfield.—The Smelter Smoke Litigation.

The mine operators of Beaver county expect to get relief from the fuel famine within the next week and have received assurance from the coal and railroad companies that their demands for coal will be met. With the exception of the Horn Silver at Frisco and a few small properties, every mine in Beaver county has been closed for the past two weeks, including the Cactus properties of the Newhouse corporation. The Cactus mill has been provided with equipment sufficient to double its capacity.

The Rio Grande Western Railroad Co. has completed its second track into Bingham as far as the Utah Copper Co.'s mine. The Copper Belt railroad, upon which a majority of the producers at Bingham have depended to move their ores, has been unable for several months to handle the traffic coming to it.——The mill of the New England Gold & Copper Co., at Bingham, is being furnished with additional equipment. About 1,000 ft. of development has been done below the lower adit level during the past year, exposing enough ore to keep the mill going for two years. The plant is producing 12 cars of concentrate monthly, valued at about $600 per car.—— The negotiations looking toward a consolidation of the Standard Copper and Bingham Central mines have not reached a conclusion.

The management of the South Columbus Consolidated, at Alta, expects soon to make regular ore shipments. Two important veins have been recently developed in this mine, one of them assaying rich in copper and gold, and the other in silver and lead.

The Nevada Gold Butte Mines Co. states that in their Eureka Hill property a drift on the 80-ft. level has cut a lode showing pay-ore 28 in. wide. A sampling gave returns of $18.80 in gold. The property is near Gold Butte, Nevada. This, with other developments, justifies the erection of a small mill and a site for it has been secured on the Colorado river, about 1½ miles from the mine. Charles F. Porter of Keith block, Salt Lake, is the company's purchasing agent.

The construction of a railroad, to be a feeder for the new Western Pacific, will be built during the present year to provide transportation for the Western Utah Copper Co.'s mine in the Deep Creek district. The mine is in condition to produce heavily. A controlling interest is owned by F. Agustus Heinze and associates, H. H. Green of Salt Lake being the manager.

The annual report of Charles M. MacNeill, president of the Utah Copper Co., shows that during the last fiscal year the Bingham mill, notwithstanding that it was used largely for experimental purposes and was handicapped by poor railroad service, treated enough ore to bring an income of $246,785. From this sum was deducted the interest on the issue of first mortgage 7% bonds amounting to $52,500; the bonus of 5%, or $37,500, for the compulsory retirement on this issue, taxes, and extraordinary expenses amounting to $6,142, leaving a net income of $150,643. The first bond issue of $750,000 par value, bearing interest at the rate of 7%, was retired July 1, 1906, necessitating a bonus of 5%, or $37,500, under its terms. The new issue of first mortgage 6% bonds, aggregating $3,000,000, dates from January 1, 1906; $1,740,000 of this amount was called prior to July 1, 1906, with the balance available as needed. The company has under construction a concentrating mill at Garfield, in Salt Lake county, of 3,000 tons daily capacity. The initial unit of 1,500 tons will be ready about March 1 and the second unit about July 1. The ore to be treated will come from the Utah Copper mine at Bingham, which averages about 2% copper, with small values in silver and gold.

The ore shipments from Park City last week amounted to 1,278 tons, the contributing mines and respective amounts being: Daly Judge, 556; Little Bell, 37; Silver King, 473; Daly West, 200; Crescent, 12.

The annual election of the Silver King Mining Co. resulted in the election of the old board of directors, with David Keith as president and Thomas Kearns, vice-president and general manager.

The appeal in the smelter smoke cases has been filed in the United States Court of Appeals at St. Louis and will probably be reached by that tribunal about next July. These are the cases the trial of which resulted in the now famous decision of Judge John Marshall in which he enjoined four smelting companies operating in the Salt Lake valley from treating ores, or any combination of ores, containing over 10 per cent sulphur. The decision was rendered November 12, last, effective 30 days from that date. The smelting companies contend the damage to their business and to the mining interests of the State will be much greater than to the complainants if the injunction remains effective. The complainants are James Godfrey and 408 owners of property aggregating 9,000 acres of land near Salt Lake City, adjoining the plants of the American Smelting & Refining Co., the Utah Consolidated Mining Co., the United States Smelting Co., the Bingham Consolidated Mining & Smelting Co., and the Bingham Copper & Gold Mining Company.

Cripple Creek, Colorado.

New Hoist on the Theresa.—Tramway for the Cresson.—Good Ore in the Gold Sovereign.—British-American Dividend.—Treatment of Dump Ore.—Low Rate of Transport Secured.—Sinking the Portland Shaft.—Other News.

A new hoist has been installed at the Theresa mine of the Golden Cycle Co., on Bull hill. The output of the Theresa up to the present time has been hoisted through the Cycle shaft, which, together with the production of the latter mine, was more than that shaft could conveniently handle. The shaft on the Theresa will be sunk from its present depth of 1,000 ft. to connect with the raises being made from the 1,200-ft. level of the Golden Cycle. A large orebody discovered at this depth in both properties will be energetically worked to keep up a production of 4,000 tons per month.——Work is well advanced on the aerial tramway being constructed from the Cresson mine of the Bull Hill Mining & Development Co. to the broad-gauge tracks some 400 yards above the

mine on Bull hill. Delay and extra expense in hauling caused by heavy roads during bad weather convinced the management that a tramway whereby the ore could be transported direct into freight-cars would soon pay for itself, and save the company money. The output of the Cresson mine is in the neighborhood of 2,000 tons per month, averaging $20 in gold.

Three shifts of men are being employed sinking the shaft of the Gold Sovereign mine on Bull hill. The shaft is being sunk from the 800-ft. level to a depth of 900 ft., 30 ft. having already been done. Some of the best ore of the Sovereign has been obtained on the lower levels and when the shaft reaches a depth of 900 ft. it is proposed to do extenstve cross-cutting of the property. An electric hoist installed on the 800-ft. level is being used in the sinking. The output of the Gold Sovereign is about 30 tons per day, most of which is produced by lessees.—— The British-American Mining Co., Ltd., operating a lease on the Dante, has declared a dividend of $1,250. Work is being carried on through the Trail tunnel of the United Gold Mines Co. The orebody has now been opened up for a length of 150 ft. and regular shipments are being made. A car of screening settled for a couple of days ago, gave returns of $41 per ton, the bulk ore running a little better than one ounce. The Christmas Gold Mining Co. lease on the mine of that name on Bull hill and owned practically by the same parties as the British-American, has declared a dividend of $1,500. The ore on this property is rather low-grade, shipping around $15 to $20 per ton, but a good tonnage is being broken.

A compressor has lately been installed by J. M. Parfet and associates in the Moffat tunnel on the ground of the Lucky Corner claim of the Doctor-Jack Pot Co. The lessees will utilize the air for the operation of six to eight drills, and push development.——It is stated that the Little Giant Mining & Milling Co., operating a cyanide mill in Pony gulch, south of the city of Cripple Creek, has obtained a flat rate of 75c. per ton from the allied railroads for the transportation of ore from any mine or dump within the district to bins to be erected at the nearest railroad point to the Little Giant mill. Any mill in the district handling low-grade custom ores, it is understood, will obtain the same rate. The Little Giant mill should be now capable of running for several years, owing to the large number of dumps and mines, having low-grade orebodies, that are contiguous to the railroad. This concession will make the total cost of transporting ore from any mine or dump in the district, contiguous to the railroad, to the mill about $2 per ton, so that ores running from $4 upward can be treated at a profit.

The Portland Gold Mining Co. is considering the sinking of its No. 2 shaft on Battle mountain. The present depth is 1,100 ft. and it will be sunk another 100 ft.; then a drift will be run to connect with the winze from the 1,100-ft. level. Good ore was obtained for nearly the entire depth of 100 ft. in sinking the winze. An air-driven hoist is being used in sinking the shaft.

The pumps have recently been started up on the C. K. & N. property on Beacon hill. For over a year the water has been at the fourth level, but has now receded so that the fifth level has been recovered and is comparatively dry. The main vein of the property is being worked between the third and fifth levels and is producing fair-grade ore. The shaft is still 100 ft. deeper than the present water-level and the management may decide to pump to that depth in the future.

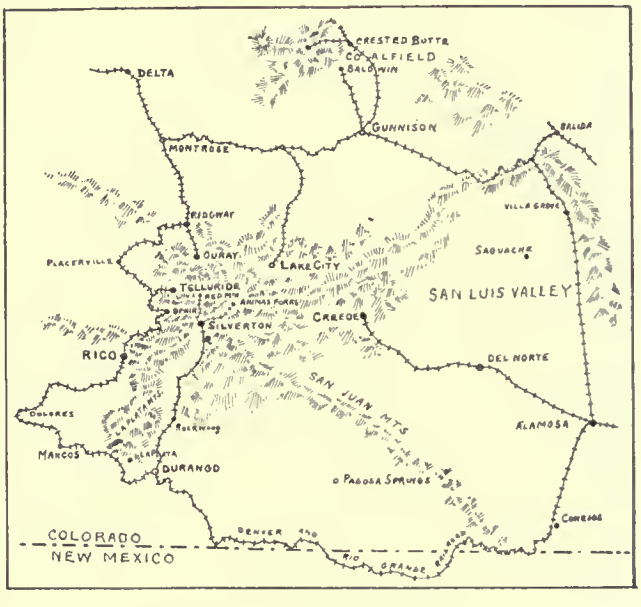
Thomas Dalzell, of Cripple Creek, has been appointed State Commissioner of Mines, in succession to E. Lyman White. The inspectors will be appointed after a conference between the Governor and the State Republican organization.

Denver, Colorado.

Guggenheim in the San Juan.—Activity Near Silverton.—The Saratoga Drained. — Resumption of Work. —Georgetown News.

Simon Guggenheim and associates have purchased 55% of the stock of the Mountain Queen Mining Co. This property is situated about three miles from Animas Forks. The Mountain Queen vein is one of the strong lodes of the San Juan region. Associated with Guggenheim are L. E. Hill, Fred Bodfish, and A. T. Holman. The bunk-house and ore-bins of the Mountain Queen were carried away by a snow-slide last fall, but will be replaced in the spring, and a tramway and mill will be erected. Several of the smaller properties in the San Juan region are making good progress and may develop into steady producers.

The Enterprise property on Anvil Mtn., two miles from Silverton, has recently shipped 100 tons of rich ore. A cross-cut tunnel is being run on this property, to cut the vein at a depth of 200 ft. The Thunder Mtn. tunnel



Map of Southwestern Colorado.

has cut the Aletha vein, at a point where it is 15 ft. wide, and contains pay-ore. The main shaft of the Edward-Ruth company which operates the Esmeralda mine, in Minnie gulch, is down 325 ft., and a large force of men is employed. All the buildings and machinery, which were broken down and crippled by the heavy snow-storms of last winter, have been repaired, and the entire mine equipment is in good shape. Shipments are made regularly to the Ross smelter.

The sixth and seventh levels of the old Saratoga mine have been drained of water by seepage into the long drift from the Newhouse tunnel, at Idaho Springs. It is estimated that 100 men can go to work at once in the ground unwatered. The entire mine will be drained in another 40 days if the water continues to recede as fast as heretofore. As soon as the mine is dry, a raise will be run from the Newhouse tunnel and the Saratoga will then be one of the biggest shippers in Idaho Springs or Central City. Ben T. Owens is the manager of the Saratoga.

The Mineral Chief at Georgetown is again a heavy shipper. This property is now owned by the Linn Consolidated Mining Co., which has just declared a 1% dividend. A tramway and mill will be built during the summer. A contract has been let to C. H. Fuller, of Idaho Springs, to drive the Lucania tunnel 1,000 ft. further.

Mining Summary.

ARIZONA.

COCHISE COUNTY.

The mining outlook in Bisbee was never brighter than at the present time, and, although the last week in January has been a quiet one among the mines, only one new strike having been reported, still the share-market has been active and trading has been excellent. The shortage of fuel is still troubling the camp, but shipments are kept up to the standard. According to the latest report, the Calumet & Arizona company has ordered another furnace for its smelter, to handle the fast-increasing output of the Superior & Pittsburg, and the Copper Queen will also add another furnace to its plant. This new furnace of the latter company will be one of the largest in the world, and will be able to handle 1,200 tons of ore per 24 hours. The Holbrook shaft of the Copper Queen will soon be in working order again, and the output will be correspondingly increased. The Calumet & Arizona always keeps a reserve fund of from three to four million dollars on hand, and is extending its operations by bonding and leasing properties both in Sonora, and in other counties of Arizona. This company has recently acquired a large area of ground in the Twin Buttes section of Pima county, and has also taken a working bond on the old Mammoth property in Pinal county. The Guggenheims, it is reported, have secured a large tract of ground adjoining the Helvetia, and the Lewisohn Bros., of New York, own the Rosemont property near there.—— The Denn-Arizona is still the feature among Bisbee mines, and another good body of ore has been struck in the cross-cut being driven from the drift on the 1,000-ft. level.—— The Shattuck continues its usual shipments, and the stope between the 700 and 800 levels is still producing good ore.—— The diamond-drill hole of the Wolverine & Arizona is down 750 ft.—— The Cochise is cutting a station on the 600 level, and is stoping from the raise on the 300 level.—— The ore-bins at the Junction are nearly completed and shipping will soon start.—— It is reported that Jack Hoatson, formerly foreman of the Lake Superior & Pittsburg, has been appointed general manager of the company's interests in the Huachuca mountains.

YAVAPAI COUNTY.

An assessment of 5c. per share has been levied on the stockholders of the Black Rock company, near Congress. Work will be resumed at this property at once.——Owing to the scarcity of miners, the Goddard mine has closed down. The hoist will be kept in operation and the mine will be kept free of water, until more miners can be secured.——The Interior Mining & Trust Co. has received a shipment of heavy machinery, including a large engine for the mill, and engines and dynamos for the concentrator, pumps, and other machinery. The 100-ton mill will soon be in operation.

YUMA COUNTY.

The Felix Mahew mine, near the King of Arizona, is reported to have been recently sold to New York and Denver capitalists. The strike on this property was but recently made by Mahew, while searching for water for his burros. The purchasers are C. H. Fay and E. M. Rogers of New York City and R. K. Humphreys and F. N. Rogers of Denver, and the price is given as $300,000.

CALIFORNIA.

AMADOR COUNTY.

The Climax mine is being unwatered, and the 10-stamp mill will start at once.——Charles Levezz has a shaft down 80 ft., which is equipped with a gasoline hoist. The 5-stamp mill is running continuously.——The Liverpool tunnel is in 200 ft. and is expected to cut the Clinton lode in 20 ft. more.

INYO COUNTY.

A contract has been let to drive the adit of the Dunlap mine another 100 ft.——At the Black Canyon Co.'s property, work is progressing, and a silver-lead vein was encountered in the lower tunnel.——The mill of the Bullion company has started and is expected to run for an indefinite time, as a good supply of ore is blocked out. The shaft will be sunk to the 500-ft. level.——The annual report of the Casa Diablo Mining Co. shows that company to be in good condition. A second vein was struck by the adit, at a depth of 450 ft., and an upraise from a depth of 325 ft. to the surface exposed some good ore. Over 1,000 ft. of drifts have been driven, and the mill will be kept running continuously when it is completed.

MODOC COUNTY.

(Special Correspondence).—Interest is being manifested in the gold mines of the Hoag mining district, which was discovered a little more than one year ago, and several companies have been formed to develop properties. The nearest towns are: Fort Bidwell, about five miles from the northwest corner line of the State of Nevada, on the California side, and New Pine Creek, on the California and Oregon line. The country is easier to get into from the Bidwell side, a new road having been built last summer by the Mines Venture Syndicate, a Los Angeles company, from Bidwell to the mines.——There are several companies at work there. Among them are the Bidwell Discovery Gold Mining Co., and the Barret gold mine, operated by McCleary & Schauer, Colorado mining men. The Mines Venture Syndicate Co.'s properties are: The North Star company, and the Bidwell Consolidated company. There are several properties being developed by individuals, among them is the Turner, Williams & Mason property which has a good showing; they have nearly $6,000 worth of ore on the dump taken from a lode about six feet wide. The cut on this vein is about 20 ft. long and about 8 or 10 ft. deep. The lode can be traced by outcroppings, trenches, and open-cuts, for at least 500 ft. Assays have been made from this lode running well in gold.——Another good property is the Wade, Reed & Plummer. The principal values show in a large porphyry dike about 300 ft. long, and 160 ft. wide. This dike averages over $4 per ton, and several small stringers will run about $20 per ton.——Another property close by is known as the Laughlin, or Josephine. They have ore running about $20 per ton. The rock in the Laughlin shows free gold.——The claim known as the Kalfader and also the Barret shows some free gold, some of their rock assaying $200 per ton.——The Seitz copper mine, about six miles south of the gold belt, has a copper showing assays from which run from 6 to 80% copper. The country has an abundance of timber and water, and some water-power is available. The prevailing formations are porphyry, rhyolite, phonolite, and dacite. Iron and manganese are found with the ore, which is usually a porous sugary quartz. The climate is magnificent, the altitude of the mines being about 8,000 ft., and of the towns and valleys about 5,000 ft. There will be much activity in this field this year, as many of the properties are planning mills. No doubt there will be some ore shipped.——North of the Hoag district, across the Nevada and California line and about 40 miles from Fort Bidwell, there was another strike in August of 1906, in a place known as Windy Hollow.——The first strike was made on the Jumbo claim, owned by Loftus Bros. Several hundred people rushed into the district and many claims were located.——The general topography of the country is similar to Goldfield, Nevada, the formation being practically the same. Several companies have been formed and are operating in this district. Water and timber are not so plentiful in Windy Hollow as in the Hoag district near Bidwell, but it is only a few miles to water and timber. Many Tonopah and Goldfield people are in these districts. The way to reach this place is from Reno, Nevada, over the Nevada, California & Oregon Railway to Alturas, then by stage to Bidwell, one day's ride from Alturas. Then by stage from Bidwell to Windy Hollow, one day's ride. Or one can go on the Southern Pacific to Thrall, Cal., take the railroad then for Klamath Falls, then by stage to Lakeview, Oregon. It is 15 miles from Lakeview to the Hoag district on New Pine creek, and it is 30 miles from Lakeview to the Windy Hollow district. Stages run from all these places.

Fort Bidwell, Jan. 22.

PLACER COUNTY.

Vade Gooldsby is negotiating for the Mississippi mine, near Newcastle. This property has not been worked for 40 years.——The Peckham Hill tunnel is in 2,000 ft. and slate is the only rock encountered. If extended to Forest Hill, it will cross seven channels and 100 old tunnels. Many claim-owners will work their properties through this tunnel. The grade is about 75 ft. to the mile, and there is a good millsite at the mouth of the tunnel, and a mill will have to be erected, as the gravel is all cemented. It is estimated that over $40,000,000 in gold has been taken out of the mines in the vicinity of Forest Hill.

SISKIYOU COUNTY.

About 500 men are employed in the Blue Ledge copper country, near Hutton.——The Morrison & Carlock mine in Quartz valley has resumed operations, after a shut-down necessitated by the destruction of the power wires by the heavy storms.——The Lanky Bob mine on White gulch, in the Liberty district, and the Ethelyn mine, on Horse creek, are closed down on account of the cold weather.

TUOLUMNE COUNTY.

(Special Correspondence).——Good ore is being milled at the App mine, at Quartz. High-grade copper ore is being shipped regularly from the Golden City mine, situated near Cooperstown, in the western part of the county. The shaft, at present 250 ft. deep, will be sunk to 500 ft. Many years ago this mine was a profitable gold producer.——Operations on an extensive scale will soon be in progress at the Clio mine, near Jacksonville. Considerable surface work has been done during the past few weeks. It is thought the mill will be started by March 15.——A shoot of rich ore three feet wide has been uncovered in the Soulsby mine, at Soulsbyville. The new orebody was found in driving from the Pennsylvania shaft, at the 400-ft. level.——The sale to Denver people, of the Turnback mine, situated one mile north of Tuolumne, is reported. The vein is only a few inches wide, but assays show $31 gold per ton.——The company, which recently acquired the Dondero gravel mine and other adjoining properties, at Yankee hill, expects to begin hydraulic mining on a large scale by March 1. A boarding-house, bunk-house, blacksmith-shop, office, and other necessary buildings will be erected at once.——It is probable that the Tuolumne mine, situated north of Soulsbyville, will soon be in operation. It is said that in the early days it was worked profitably until water-level was reached, when it was abandoned. According to reports the last ore milled yielded $125 per ton, and the sulphides assayed $300. The average width of the vein is 12 inches.

The Stanislaus Electric Power Co. has contracted for the machinery for the 36,000-h.p. electric power plant to be situated 30 miles northeast of Sonora, on the Stanislaus river, in this county. The company has already expended an immense amount of money in constructing wagon roads, a railroad, sawmill and flume, and in doing other preliminary work. A reservoir having a capacity of one billion gallons will be built in Relief valley. It is expected that by the end of the present year the company will be ready to furnish electric power in this county and other parts of Central California.

Tuolumne, Jan. 28.

COLORADO.

CLEAR CREEK COUNTY.

The tunnel of the Capital Prize Mining Co. has been driven 4,200 ft. into Griffith mountain. Fifteen veins of greater or less importance have been crossed, but have not been prospected, as it was desired to reach the Etna vein without any delay. This vein has been opened quite extensively, and a good body of concentrating ore is said to be available.——The Two American Sisters Co. has about completed the extensive equipment that it has been installing. The new dam and power plant are completed, and the new mill, which is to work over the old dumps, is ready to run, and will have a capacity of about 50 tons per day. This is an old property, which has produced about $2,000,000. A good strike has been made on the 275-ft. level driven west from the Headlight shaft. J. J. White is the manager.—— A new strike is reported in the old Seven-Thirty mine. The discovery was made in running a cross-cut from the Hercules tunnel, at a distance of 3,000 ft. from the portal.—— J. M. Shaller, of Denver, has leased the Kaverne mill, at Dumont, and is installing a steam plant there. Ore from the Mammoth property at Silver Plume will be shipped here and treated in the mill.—— The lease owned by Nelson & Kermode on the Gold Dirt property of the Empire Tunnel Co. is in good shipping ore. Recent shipments have been made to the Denver smelters, and the concentrating material is hauled to the Empire mill.—— The Mineral Chief property, on Republic mountain, has started shipments of smelting ore. As soon as the mill located near the mouth of Moline tunnel is in running order, this property will send concentrating ore there.—— A lode has been intersected by the St. Paul tunnel, being driven into Green Lake mountain. The vein was cut at a distance of 1,150 ft. from the portal of the tunnel. The tunnel is headed for the St. Paul lode, which still lies 650 ft. from the face, and is supposed to be an extension of the Colorado Central.—— The new Nashatah mill, situated near the portal of the Diamond tunnel, is completed, and is concentrating the ores left on the old dumps of the Corry City, and Wisconsin mines. A tunnel has been driven under the Diamond tunnel dump, in which runs a belt conveyor. Onto this conveyor the ore will be fed from chutes, the belt conveying the material to the Huntington mill. Twenty Card tables have been installed, and no jigs will be used. The mill is run by electricity, and is said to be the best equipped and most modern plant in Clear Creek county.—— A syndicate of Denver men has taken over the Annie May group of claims, situated on Columbia mountain.

IDAHO.

IDAHO COUNTY.

A rich strike of ore is reported from the Hope property, which joins the Blue Ribbon property on the west. The values are free milling and the gold is coarse, with but few sulphides.——The Clearwater group of claims will be actively worked in the Spring. The property is on the Clearwater river, five miles from Elk City. A 100-ton plant will be erected at once, using an electro-cyanide process.

SHOSHONE COUNTY.

The silver-lead region of Idaho is enjoying the greatest prosperity the Coeur d'Alene district has ever known. Nearly every mine in the region has increased its working force, and now there are about 5,000 men employed, as compared with 2,500 one year ago. The eight-hour system is in use in both mines and mills, and $3.50 is the standard daily wage. The operators have paid over $6,000,000 to labor during the last 12 months. The following gives an idea of the distribution of this working force among the companies operating in the region: The Morning mine at Mullan employs 400. C. K. Cartwright is superintendent; the Standard-Mammoth at Mace employs 550 men under R. H. Pascoe, the superintendent; the Tiger-Poorman at Burke employs 200 men. J. F. Bergen is superintendent; the Hecla mine at Burke employs about 175. J. F. McCarthy is the general manager and Fremont S. Rowe, foreman; the Hercules has a force of about 200 men at its property up Gorge gulch, above Burke. Frank Franz is in charge, and Harry L. Day is general manager; the Frisco mine is being re-opened, and employs about 100 men at Gem. This number will be increased to 200 when the mill starts. Fred Burbridge is the manager; the Snowstorm, a copper property at Mullan, employs 250 men. Wilbur Greenough is the manager; the Hunter mine works 80 men, under James T. Gearon; the Success mine, producing lead and zinc, employs 75 men up Nine Mile creek, two miles above Wallace. The property is managed by H. F. Samuels. The Black Cloud, in Nine Mile cañon, employs 50 men under George Pressler; and the Tamarack & Chesapeake uses about 40 men. The Bunker Hill & Sullivan Co. at Wallace employs 500 men under Stanly A. Easton, the general manager; the Last Chance mine, below Kellogg uses 250 men under D. W. Peeples, the superintendent. In addition many men are at work in the hills, on prospects. It is estimated that 300 men find work outside of the producing mines near Burke; 500 men around Mullan; 500 near Saltese and Iron Mountain, Montana; 300 in the Murray district;

60 men in Government gulch below Wardner; 60 in the vicinity of Osburn, and 50 in Placer creek. Altogether, the Cœur d'Alene region is having a decided boom, new companies have been organized during the past year at the rate of one company every 67 hours, or 141 incorporations for the year, the stock exchanges are doing a big business, mineral production is increasing, and the mining industry is steadily undergoing a wholesome growth.

NEVADA.

LINCOLN COUNTY.

(Special Correspondence).—A carload of hoists for mines in Crescent arrived at Nipton, Cal., several days ago. The Crescent-Searchlight, Superior-Nevada, Wathena, Golden Crescent, and Oro-Nevada all have machinery on the ground. Unknown parties are bonding the Calavada group, situated three miles south of Crescent. Five parallel veins are traceable on this property. The ore is similar to that found on the Tiger and Nippeno mines and assays of surface samples show values up to $36 in gold. All the properties in the Crescent and Searchlight districts have shown better values at depth than on the surface. The Crescent townsite is laid out on an almost level plateau in the heart of the district, west of the Searchlight valley and east of the Crescent hills. There is plenty of water available and the camp has a public school and library.——The Superior-Nevada company is developing its King Solomon mine, under the management of G. W. Huntington, and has 10 ft. of ore exposed, running from $8.20 to $23. The company will install the machinery necessary to sink to water-level. A shipment will soon be made, as there is some rich ore now on the dump. The shaft is all in ore at a depth of 135 ft., and the presence of galena is noted at this depth. Jas. Sword has started another shaft on the property, several hundred feet north of the present shaft, for water. The main shaft has attained a depth of 165 ft.—— H. H. McClure is working two shifts of miners on the Monte Cristo, adjoining the Shreveport and Colorado properties. A cross-cut tunnel is in 35 ft. and the management expects to intersect the vein at a distance of 110 ft. The country rock is porphyry and the values occur in the granite and porphyry contacts.——The Searchlight Gold Extraction Co. is sinking a shaft on the Jumbo group, with the intention of going down to water-level. The values found on the surface of this property are good and the management believes that they will encounter pay-ore at depth. On the Santa Rita claim, the vein has been prospected and stripped for a distance of over 100 ft., with the expectation of opening up an ore-shoot on the surface. The vein is five feet in width and the values average $13 in gold across the vein. The veins have an east and west trend and are at the contact of diorite and porphyry. This property is three miles south of Crescent and adjoins the Turquoise mine of the Tiffany syndicate.——Sinking is being accomplished on the Wathena mine of the Ajax Bullfrog Co. under the management of Geo. Straub. The shaft is on the vein, which dips at an angle of 45°. The lode is three feet in width, and some good ore has been produced. The values are increasing with depth, and, at the 175-ft. level, 18 in. next to the hanging wall runs $145 in gold and copper.

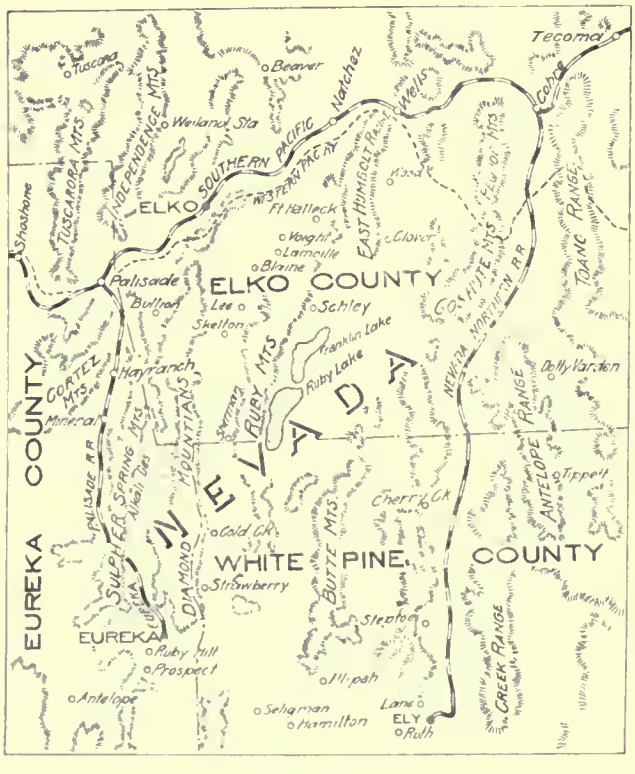
NYE COUNTY.

Rhyolite has formed a stock exchange, the organization has been incorporated, and the membership is limited to 200. The charter membership of 75 is entirely filled, and 50 seats will be on sale for the next 90 days, at $200 per seat. The list of officers and committees includes the following names: G. W. Thatcher, J. L. Cadogan, G. K. Vaughn, G. B. Keenan, O. O. Kincaid, and B. F. Taylor.——The work on the 400 level of the Montana Tonopah continues to uncover rich ore, some of which shows ruby silver. During January, 260 tons were shipped to Millers, but nothing was done with the ore, owing to the closing of the sampling works of the Western Ore Purchasing Co., on account of lack of fuel. The new 40-stamp mill is ready for the roof, and all the machinery is on the ground.——It is announced that C. M. Schwab has purchased the Brown Palace group of claims, at Rosebud. Wingfield & Nixon and T. L. Oddie are also said to have secured ground in this district.

OREGON.

BAKER COUNTY.

(Special Correspondence).—About 30 miles southeast of Baker City, there is a revival of interest in placer mining similar to that of 40 years ago. Burnt river and its tributaries have long been noted for their placer gold, but the supposition has been that the richest diggings in that vicinity were exhausted. On Clark creek, which empties into Burnt river, there was in the early '70s a camp of 2,000 people, engaged in extracting gold from the bed of that stream. Later, the camp disappeared.——It now appears that the old channel from which hundreds of thousands of dollars were taken, has been re-discovered, and Richard Eckman, acting for John L. Rand and W. H. Packwood, is driving a tunnel to tap it. This adit is already in 250 ft. and the men expect to strike bedrock any day.——Great interest in placer mining is centered in the Cornucopia district, about 40 miles northeast of Baker City. On one of the tributaries of Eagle



Map of Eastern Nevada.

creek, which was once noted for its rich diggings, another old channel has been discovered. One tunnel has tapped this channel at bedrock and the gravel which is now being taken out yields $5 per cu. ft. The gold is coarse. What is known as the Blair, Herbert & Underwood property, was the first on which a tunnel was driven to this old channel, and in the rush which followed the ground was taken up on both sides of them, and other tunnels are now being driven. Charles Slade, Jos. Cooley, and Lincoln & Hunt, are among the locators, and they are driving toward the bedrock of the old Boulder creek channel. The estimated distance they will have to drive is 60 feet.——An important deal is the transfer of the North American Mining Co.'s property, at Burkemont, to a New York corporation, under bond, for $1,500,000. D. W. C. Nelson, the general manager of the North American, has just returned from New York. At the stockholder's meeting, which was held in Des Moines, Iowa, on the eighth of January, the sale was confirmed. The New York parties will begin work on Feb. 7. This property is one of the most prominent on the copper belt here. Nelson will be retained as superintendent and development work will be started on this property at once.

Baker City, Jan. 26.

JACKSON COUNTY.

The Lakeview Co. has made a new strike in the Coyote hills. The lode, as opened, assays one ounce per ton.—— The Briggs mine, together with the Forest and Blossom groups of claims, situated some 30 miles northwest of Ashland, has been taken over by a syndicate of Amsterdam.

Personal.

W. S. NOYES is in Texas.

HERMANN A. KELLER is at Planet, Arizona.

MARK L. REQUA has returned to San Francisco.

G. A. DENNY has been examining mines at Butte.

ARTHUR L. WALKER has arrived from New York.

FREDERICK H. HATCH has returned to London from Siberia.

GEORGE W. MAYNARD has returned to New York from Mexico.

H. C. CALLAHAN has been at Denver and is now in Nevada.

C. W. PURINGTON sailed from Boston for London on January 23.

WILLIAM BAYLEY, of Los Angeles, has been on a visit to San Francisco.

GEORGE J. BANCROFT is examining mines at Cherry Creek, Nevada.

HAROLD WILSON has opened an office at Denver. His address is P. O. box 243.

W. R. RUST and EDGAR NEWHOUSE, of the A. S. & R. Co., are in San Francisco.

WILLIAM RUSSELL, of Denver, is examining mines in Madera county, California.

MAURICE M. JOHNSON is accompanying Samuel Newhouse on his visit to Cobalt.

ERNEST BAMBERGER is now general manager of the Ontario & Daily mines, in Utah.

E. A. H. TAYS postponed his trip to British Columbia and has gone to Bullfrog, Nevada.

A. D. BENTON has been appointed manager of the Paymaster mines, near Tucson, Arizona.

WILBUR E. SANDERS recently examined some prospects in the Greenwater district, California.

A. M. ANTOINE has received an appointment with the Brazilian Concessions, Ltd., in Brazil.

J. H. ROBESON, of Silver Plume, Colorado, has been appointed manager of the Nipissing mine, at Cobalt.

SAMUEL NEWHOUSE has gone to Cobalt, Ontario, in his capacity as president of the Nipissing Mines Company.

RICHARD R. HEDLEY has resigned as manager of the smelter of the Hall Mining & Smelting Co., at Nelson, British Columbia.

W. A. WALKER, of Mt. Pleasant, Ohio, has been appointed manager for the Gold Dust-Puzzle mines at Breckenridge, Colorado.

JAMES W. MALCOLMSON is leaving El Paso and will reside at Kansas City. He has been appointed general manager for the Stilwell companies.

H. A. BARKER, formerly receiver of the Golden Cross property at Hedges, is at Metcalf, Arizona, in the interest of the Crawford Gold Mining Company

CHARLES C. GATES, former superintendent of the French Mountain Mining Co., at Red Cliff, Colorado, is now superintendent of the Nevada United Mines Co., at Ely, Nevada.

P. L. WILLIAMS, JR., who has served the Utah Consolidated Mining Co. at Bingham as superintendent of the Highland Boy mine, has resigned and has accepted the position of general superintendent of all the mines under the general management of ERNEST BAMBERGER of Salt Lake. These include the Daly West, Daly, Ontario, and Naildriver mines at Park City and the Ely Witch at Ely, Nev. Mr. Williams has been succeeded at the Highland Boy by MIKE RHINEY, of Butte, Montana.

Obituary.

CAPT. T. F. SINGISER, formerly delegate to Congress from the Territory of Idaho, who was identified with mining affairs in the Salmon river country, and organized the American Flag Mining Co. at Park City several years ago, is dead. He had been an invalid for the past year.

California Miners Association.

W. C. Ralston, president of the California Miners Association, has announced the following executive committee: Charles G. Yale is chairman; the other members are E. B. Braden, S. W. Bradley, Ross E. Brown, R. Gilman Brown, Frank H. Buck, A. Carrigan, S. B. Christy, Thomas Clark, Edward Coleman, C. W. Cross, A. Hamilton, J. J. Hamlin, J. D. McGilvray, B. M. Newcomb, T. A. Rickard, Louis Rosenfeld, Louis Sloss, George W. Starr, George Stone, and Lewis T. Wright.

Every mining interest of the State has representation on the committee, including copper, quicksilver, smelting, oil, cement, building stone, and dredge mining. The officers of the Association are W. C. Ralston, president; C. H. Dunston, vice-president; John Hendy, treasurer.

Trade Treatises.

ALLIS-CHALMERS Co., of Milwaukee, issue Bulletin No. 1,045, describing rotary converters.

A. LESCHEN & SONS ROPE Co. publish a handsomely illustrated book on the 'St. Louis of Today.' On one of the pages their own large establishment is pictured.

SMITH, EMERY & CO., of San Francisco, issue a pamphlet detailing the work they perform, which includes physical tests, inspections, factory processes, water rectification, and analyses.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

BLACK SAND is often a mixture of the magnetic oxide of iron, magnetite, and the iron-titanium oxide, ilmenite or 'menaccanite,' as it is sometimes called. The last mineral resembles magnetite, though its magnetic quality varies greatly. The best test for ilmenite is to boil some of its powder in strong hydrochloric acid, and then add a piece of metallic tin and boil to small bulk. The titanium in the mineral will impart a fine violet color to the solution.

CALCITE AND ARAGONITE have the same chemical composition, namely, carbonate of lime. Aragonite is of rare occurrence compared to calcite, yet some marbles, especially the banded and stalactitic kinds, are really this mineral, and not calcite. A test not generally known that will distinguish them, is to boil a little of the powdered mineral in a solution of cobalt nitrate. The real color of the solution will remain unchanged with calcite, but with aragonite it will change to violet.

LUBRICANTS are tested in about six ways: (1) By chemical analysis; (2) for specific gravity; (3) for relative viscosity when new; (4) for gumming action; (5) for flashing and burning points; (6) generally, by the testing machine. The last is the most efficient, and in its essential features consists of a pendulum hanging on the test journal, whose brasses can be adjusted for any pressure by a screw. The journal being rotated to the right, the pendulum moves to the left, and a scale at once indicates the friction per square inch of journal.

UNDER the more recent systems of rock nomenclature, the terms rhyolite, liparite, and quartz-porphyry, are grouped together as interchangeable. As a matter of fact, the name 'rhyolite' is directly derived from the Greek word meaning 'to flow,' and perhaps this term should be applied to that class of eruptive rocks which typically shows some evidence of flow structure, the term quartz-porphyry covering the remainder of the class. Liparite is a term little used, having its derivation from the Lipari islands, near Sicily, where this rock is much in evidence.

THE average eastern slope of the Rocky Mountains seldom exceeds 10 ft. per mile, which is about one foot in 500, equal to an angle of only seven minutes. On the west the average slope is but little less gradual. The rise on the east continues for 600 miles, and the fall on the other side for nearly 500 miles. The mountain mass, therefore, is not a narrow barrier between the east and west, as might be inferred from the ordinary maps, but a vast, gentle swell of the surface, having a base 1,000 miles in breadth. In the Sierra Nevada, the western slope is the gentler, being between 100 and 250 ft. per mile, and the eastern, for a large part of its length, 1,000 feet.

THE mean height of the continents above the sea has been estimated at nearly 1,800 ft. The mean height of each is stated as follows: Europe, 975 ft.; Asia, 2,880; North America, 2,000; South America, 1,750, and Africa probably about 2,000 ft. The mean height of the United States, Alaska excluded, is 2,500 ft. Colorado is the highest, averaging 6,800; Wyoming second with 6,700, and Utah third with 6,100 ft., while Delaware only averages 60 ft. above sea-level. The lowest spot in the United States is Death Valley on the southeast border of California, which descends 480 ft. below the sea-level, and is bounded on the east by the Funeral mountains, 7,000 ft., and on the west by the Panamint range, 11,000 ft. high.

IN the working of toothed gears, the smoothest action being observed to occur when a very small pitch was used, Dr. Hooke invented his 'stepped gearing' to obtain strength and smooth action at once. These are made use of in many of the big engines, both hoists and compressors, at the Calumet & Hecla mine. A further development in gearing brought in the 'single helical' gearing, which simplified the casting. And this in turn was followed by the 'double helical' teeth, now so common, which have been adopted to avoid endlong pressure on the bearings caused by the single helical teeth. They are machine moulded from two half patterns, and work smoothly if well formed, and are said to be stronger than ordinary teeth.

WHEN air is compressed into a smaller volume, if the temperature remains constant, the pressure increases directly in proportion to the decrease in volume; that is, if the volume is one-half, the pressure will be doubled; if one-third, the pressure will be trebled, and so on for any decrease in volume. There is, however, another and most important factor in the problem that must be considered in all cases except the lowest terminal pressures, namely, the increase in temperature and consequent increase in volume due to the heat developed during compression. When air is compressed, the work done during compression is converted into heat, which must be taken up by the air compressed, the result being to raise its temperature and increase its volume, thus adding largely to the work required to be done.

MOLYBDENITE AND GRAPHITE are two minerals that closely resemble each other, especially when they are disseminated as small flakes in a rock. They are both soft and have a greasy feel, and they occur in various ways from minute scales to large foliated masses. The larger flakes can readily be told apart by the color as molybdenite is bluish lead-gray, while graphite is dark steel-gray to dull black. However, when either occurs in small specks or particles in a rock, the color cannot always be judged. One of the simplest tests is to mix some of the rock powder containing the mineral with potassium nitrate on a thin piece of platinum or tin and apply a flame beneath. Graphite will deflagrate, that is, will burn with miniature explosions like grains of gunpowder, whereas molybdenite will remain unaffected. Very small amounts of graphite in a rock can be detected by this method.

INFUSORIAL earth and tripoli include all porous siliceous earths, composed of organic fragments, such as infusoria or diatoms, which have accumulated either on ocean bottoms or in ponds. Such deposits are quite common in the coastal plain area of Maryland, Virginia, Georgia, and Alabama, where they form beds several feet in thickness, generally interstratified with the Tertiary sands and clays. Deposits in Missouri are different in their nature, consisting of the residual silica left by the leaching of an impure limestone. The largest and best known deposits are those in northern Germany, where they are found from 15 to 18 ft. below the surface in a bed varying from 18 to 45 ft. in thickness. This is exported to all parts of the world. Infusorial earth and tripoli are used chiefly for polishing powders and scouring soaps, while their porous character makes them valuable as an absorbent for nitro-glycerine. As a non-conductor of heat they are of value for steam-boiler packing, for wrapping steam-pipes, and for fire-proof cement. The tripoli of Missouri is used for water-filters.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

The Amalgamation of Copper Ore.

The Editor:

Sir—In your issue of October 20 there is an article on 'The Amalgamation of Copper Ore' by Arthur H. Keller, of Honduras. This article comes to me like an echo of twenty years back; in 1886 I was a subscriber to the MINING AND SCIENTIFIC PRESS, and was looking for silver ore in a district of Montana where the formation was presumably Carboniferous limestone. Silver was at that time all the go, and the great Granite Mountain mine in my neighborhood was beginning to yield its wealth. The ore in my locality was a gray copper (fahlerz) and a black mineral (likely polybasite), which some of the miners called a copper-silver glance; some of these minerals were oxidized, forming an ore as Mr. Keller describes.

In the gulch, James Hamond was running an arastra on this ore, using what he called Aaron's process; at that time freight and treatment were $40 per ton. Mr. Hamond had learned Aaron's process somewhere in Nevada. In the advertising columns of your paper I saw a book entitled 'Testing and Working Silver Ore' by Charles Howard Aaron, who was then an able and conscientious metallurgist of the Pacific Coast; in it Aaron describes his process minutely; it consists in grinding the ore in an arastra or some other way, an arastra preferred, wet, making a pulp of the consistence of mortar, heating by introduction of steam to boiling point, then adding 5 to 10% common salt and from 5 to 20 lb. bluestone per ton of ore. After being heated and the bluestone and salt added, the barrel is revolved for an hour or two; next the mercury is added, and scrap copper (or copper balls or copper bars) fastened lengthwise in the amalgamating barrel is introduced; after from five to ten hours revolving, the amalgamation is finished. This process cannot be used in an iron amalgamating pan, as the copper sulphate and chloride are decomposed by iron, and not only is it destroyed, but the copper enters the silver amalgam, making it base. Usually Aaron's process yields a retort of 0.925 to 0.950 fine, and no loss (or only a small one) of quicksilver. James Hamond told me that he lost one-half to three-fourths the bullion weight in mercury, that is, 50 lb. mercury to 100 lb. bullion, including all losses; careless work, I considered it. In the book of Mr. Aaron, he mentions a German metallurgist who came to Virginia City to introduce a process called the 'Dichloride of copper process', but the companies did not take it up and Mr. Landswirth, the inventor, left. The dichloride of copper, which is cuprous chloride, Cu_2Cl, is made by boiling bluestone, salt, and metallic scrap copper together, the proto-chloride of copper which forms from bluestone and salt, CuCl, being reduced by the metallic copper to the sub-chloride, Cu_2Cl, a white powder soluble in salt brine. This was the active agent in Aaron's and Landswirth's processes.

I experimented with Aaron's process with the ore described and extracted from 85 to 93% on ore carrying 25 to 40 oz. silver per ton; the tests were made on two and a half pound lots. I also tried rich ore 400 to 500 oz. Ag per ton, got about 80 to 85%, which, of course, would not do, for it left 75 to 100 oz. in the tailing. I made one test on low-grade ore with Landswirth's dichloride process; the result was as satisfactory as Aaron's process; I then tried copperas, the cheaper iron sulphate ($FeSO_4$), a little sulphuric acid, salt, and metallic copper; the result was good when there was plenty of green and blue carbonate in the ore; with ore having no oxide or carbonate—only sulphides of copper—the iron sulphate is useless.

The conclusion I arrived at was that in these processes sulphate of copper is necessary, first, to furnish Cu for the formation of CuCl, the sulphuric acid content of the bluestone being required to decompose the salt to liberate the chlorine. Metallic copper is necessary to reduce proto-chloride of copper to the sub-chloride, to reduce the silver chloride to metallic silver, and to protect the mercury. Metallic iron is tabooed. After separating amalgam from pulp, pulp can be run into an iron settler.

In ore having carbonate and oxides of copper, sulphuric acid and copperas can replace part or all of the bluestone.

WM. H. BAUR.

Valdez, Alaska, December 17.

Single-Stamp Mills.

The Editor:

Sir—The contribution of Mr. Algernon Del Mar with reference to single-stamp mills and consequent economy in milling practice, which appeared in your issue of November 17, and a subsequent article on the same subject by Mr. F. L. Bosqui, have interested me very much. I am indeed glad to read any expressions of experience on this question by competent engineers for there can be no doubt that it is a serious and important one and richly deserves careful attention.

I myself have been deeply interested in the tests recently conducted by the Boston Con. Copper Co. in Utah, and the results obtained there have opened my eyes to the possibilities of the single-stamp mill as compared to the old five-stamp battery. I have been positively assured by the manager of the Western Zinc Co., in southern California, who is a disinterested, competent, and reliable engineer, that this make of stamp is now crushing in their mill 10 tons of ore per 24 hours, per stamp, as against less than 3¾ tons per stamp in the old style of five-stamp battery of 1,000 lb. each, and to my certain knowledge, the results obtained in Utah are even better than this. The rapid and ready discharge, which is the chief object of this design, also produces less sliming, in itsef a feature of no small consideration.

Such results, as here quoted, might undoubtedly vary materially according to the character of the rock crushed and other attending conditions. Perhaps many of the low results in Nevada, as mentioned by Mr. Bosqui, may be due in a great measure to incompetent handling, as such is too often the case in the initial use of new devices. But when figures are obtainable from work performed by both kinds of stamps, side by side, under exact conditions, there is but little, I think, to prevent a just opinion.

In any event, I fear it will be difficult indeed for the vast majority of gold-mill men, particularly in California, to look with any respect whatever upon a mill of this character, because of their pet hobby of battery amalgamation. In my opinion, the single-stamp mill as put on the market today, is not at all adapted to that work, although the actual crushing capacity may be excellent. Nevertheless, such a vast saving in crushing as this mill promises to make, is entirely too important a consideration to be allowed to pass unnoticed, and I am glad to have this opportunity to add my little quota to the discussion.

The advent of the single stamp is bound to force the question: Is not the general cost of gold milling kept unnecessarily high, and the advancement and development of good practice retarded, as a consequence of sticking to the old custom of battery amalgamation? I admit that in some special cases, battery amalgamation may be

best. But from a varied experience of some twenty-two years, I myself, whenever opportunity permits, have invariabiy tried both inside and outside amalgamation, and have yet to find any advantage to be gained by the former. I am sure that most millmen do not understand the subject as they should, but religiously adhere to a custom, simply because it was practiced by some one before them. It must be admitted that economy in crushing may be looked for through the use of the single-stamp mill. Therefore let us take up a new arrangement of the mill throughout: In the old days all gold milling was 'free-milling,' otherwise there was no milling at all, as the proverbial Irishman would say. There was but little, if any, concentration and consequently the plates were placed under the lip of the battery, or against the battery itself. As concentration came into fashion, the machinery for this operation was placed at the tail end of everything, a matter then of no great importance, and this arrangement has been allowed to stand until the present day. But concentration has now come to be the most important feature in milling, more especially with respect to gold. Investigation shows that it is possible to move the concentrator further to the front to take the place of the plates nearer the battery, and with better results and greater economy.

Under any circumstances where concentration is employed, classifying or sizing of pulp is as necessary as any other feature of milling. No matter how fine the ore may be crushed in the mill, the pulp should be classed into at least three products, the coarse, the middling, and the slime, the latter containing particles that do not settle easily in water under agitation. He is indeed a poor millman, who cannot devise a sufficiently effective sizer with the aid of his carpenter and a little gas-pipe. But there are a number of cheap machines on the market and the purchase of one would be a profitable investment. I am aware that there are superintendents who do not regard with any favor sizing of their pulp, because, as they claim, they are crushing fine enough, yet their tailing contains value. Soft amalgam and quicksilver will escape with the tailing from concentrators, but the segregated particles of free gold will not. Any piece of free gold that will stick on a plate, will stay on the concentrator. If such a piece of gold would not stay on the concentrator, it would not stick on the plates.

With all these facts established, the arrangement of the mill should be as follows: Stamps, sizer, concentrator, slime-tables, plates.

Three-fourths of the lost amalgam and quicksilver from the plates is caused by the quicksilver escaping from the battery. The discontinuance of battery amalgamation is an economy in this case, and a further point is that the proximity of the plates to the battery causes a constant vibration that is exceedingly detrimental to good amalgamation. The waves flowing over the plates in gushes from each succeeding drop of the stamps, cause a varying rush on the surface, which prevents close amalgamation of the lighter particles. By removing the plates to a quieter locality below the concentrators and slime-tables where the product from these last may be passed over them with an even and well-regulated flow, the results would be better. For instance, the plates of a 40-stamp mill may be reduced from eight to two or three, the coarse concentrate to pass over one, the middling on another, and the product of the slime-tables on the third; and in this way, the grade of each plate may be adjusted to suit conditions favorable to good work.

In a great many cases ores contain various oxidized and other materials that have a tendency to foul the plates and thus cause loss from imperfect amalgamation. But this fouling substance would be eliminated in this way, the detrimental element having gone into the tailing, and a comparatively clean product passed over the plates. With this arrangement there should be no loss of amalgam and a close saving throughout the mill; if any amalgam should possibly escape the plates, it would go directly into the concentrate.

J. W. PINDER.

San Francisco, January 11.

Increasing Milling Capacity at Small Cost.

The Editor:

Sir — In 1900, Charles Tozer and C. D. Lane, of San Francisco, built a 10-stamp mill to treat the ore which was being extracted from a rich shoot in the Eureka mine, one of the claims now owned by the Bonita Co., in Whatcom county, Washington. The ore occurs in irregular bodies situated on the hanging-wall side of a fissure, which has a northeasterly strike through Cretaceous shale. No ore has been found in this fissure, but in the shale, which has been shattered, large bodies of ore from 12 to 60 ft. in width have been developed. The orebodies are intermixed quartz and shale. The company determined to increase the capacity to at last 200 tons per day. My attention having been called to an article, written by J. A. Wauchope, regarding slow-speed mills, the directors at my suggestion determined to install one of these mills to do the fine crushing and amalgamation, using five of the stamps as a secondary crusher. By making this test side by side, the results would enable them to determine the merits of the two systems and to form a correct judgment regarding machinery to be installed in the future. I think the information acquired from this test may be of interest to some of your readers, and therefore give a brief description of the results obtained.

A 10-ft. Lane mill was placed in front of one of the batteries, consisting of five 1,000-lb. stamps, making its intake low enough for the pulp from the battery to be delivered to it by gravity. A quarter-inch mesh No. 16-wire screen was put on the battery and the stamps were given a 6-in. drop with a 4½-in. discharge. The Lane mill was fitted with 8-mesh wire-screen and 6-in. discharge. The pulp from the mill was discharged to plates five feet wide, 18 ft. in length, and then to two Wilfley concentrators. The other battery of five 1,000-lb. stamps had a 6-in. drop, with a 5-in. discharge through a 25-mesh wire-screen, and the pulp was run over plates five feet wide and 20 ft. long, and then over one Wilfley concentrator. Hourly samples were carefully taken from the batteries (at the foot of the plates), and from the concentrators, for three days. Samples showed the saving to be:

Stamp system.	From foot of plates.	Lane system.
51%		65%
	From the Wilfley tables.	
80%		91%
	Screen test of tailing.	
90% passed	30 mesh	96%
70 " "	40 "	88 "
42 " "	60 "	66 "
36 " "	80 "	56 "
11 " "	100 "	36 "
	Screen tests of concentrate.	
97% passed	30 mesh	99%
89 " "	40 "	96 "
58 " "	60 "	92 "
51 " "	80 "	88 "
22 " "	100 "	80 "

The product from the stamps, when examined by magnifying glass, shows sharp edges and angular shapes. The re-ground product has rounded edges and globular forms. It is evident that the re-grinding process of the Lane system makes a product by abrasion that is entirely different from that of the stamps, and, in my judgment, it is better for amalgamation.

The Lane mill made six revolutions per minute and

crushed 40 tons per day of 24 hours, while the stamps dropping 96 times per minute crushed 16 tons with 25-mesh screen. The power required to drive the Lane mill with full load is 12 h.p. Judging from the present wear on tires and track, which have been in use six weeks, I estimate the cost of repairs will not exceed three cents per ton of ore crushed. The hardness of the ore we are crushing is above the average. By increasing the speed of the Lane mill from six to eight revolutions per minute, which we are going to do, I feel confident that the mill will crush at least 50 tons per day.

The cost of installation, ready to run, did not exceed $3,500. Had we installed ten more stamps, the cost would have been about $12,000. Freight from Seattle is 3½c. per pound. We would have had to build an ore-bin, increase the size of the building, and buy more plates and self-feeders, all of which are expensive. This company is greatly pleased with the above results and is preparing to install four more mills—one to be placed in front of the other battery and the remaining three to be fed by gyratory crushers.

In conclusion, allow me to state that I have been for many years an advocate of the stamp-mill process, but the experimental test recently made has shattered my former conviction.

JOHN A. STEWART,
Superintendent for the Bonito Mining Company.

Barron, Wash., January 10.

The Moore and Butters Filters.

The Editor:

Sir—Referring to Mr. E. H. Nutter's article on the Moore filter, in your issue of December 15, it seems to me that a choice between the two rival filtering systems must rest upon broader grounds than those given by Mr. Nutter. Even if experience should prove that the Moore method requires somewhat less power, and that, all conditions being equal, the Moore plant is less expensive to install, this would not by any means establish the superiority of the process.

Let us consider the vital points at issue. We can only arrive at a just estimate of the Moore and the Butters-Cassel systems by comparing operating costs, and particularly the important items of repairs and maintenance; and until such a comparison is forthcoming, no conclusion is possible. A comparison of the efficiency and operating expenses at two representative plants, namely, the Butters plant at Virginia City, treating 200 tons per day with the Butters-Cassel process, and the Liberty Bell plant at Telluride, treating 350 tons per day with the Moore process, would be extremely interesting. From my experience at Goldfield and observations at Virginia City, I can safely say that the cost of maintenance of a Butters filter is a very small item. The frames are stationary and subjected to no wear beyond the action of solutions on the canvas, and there is no shifting mechanism to require repairs. I am informed that the cost of repairs of the Moore filter at the Liberty Bell mill have been very heavy, and that breakages and certain defects in the mechanism of the plant have caused serious interruption of operations. I understand that many of these defects have been partially corrected, but they nevertheless point to fundamental weaknesses in the system.

Aside from the question of comparative operating cost—in which the Butters-Cassel filter can, I believe, be shown to possess distinct advantage—something must be said for the *stationary* filter. In most of the current discussions on filtering, this feature is barely alluded to. As a matter of fact, it constitutes one of the chief points of merit in the Butters system. The importance of keeping the filter stationary is obvious enough when we consider its true function. To ensure good work—that is, a uniform deposition and a clear filtrate—the frame must be as nearly as possible straight and true, and the canvas free from weak places, ripped seams, etc. In the interval between complete deposition and the displacing operation, we have a period of suspension during which the vacuum is reduced just enough to hold the cake in loose adherence to the canvas, yet not enough to dry and crack the cake. The maintenance of the slime cake in the best condition for the displacement by water is a delicate operation, requiring careful manipulation. Obviously, to give the best results, the filter must not be stretched or strained; there must be a uniform and quiescent condition of the filtering surface throughout.

In the Moore process, as is well known, the frames are mechanically lifted from one tank to another. To accomplish this without, to a great or less degree, disturbing the integrity of the cake, and straining the frame, is practically impossible; at least it could not be done without the use of a prohibitively delicate and expensive mechanism. However carefully the thing is managed, the filter is subjected to a strain; the unity of the cake is disturbed; minute cracks are formed, and portions of the slime-cake drop off during transfer. The seams of the canvas, subjected to an alternating tension and relaxation, weaken and finally give way, producing annoying leaks and murky filtration. The result of this straining action is not only that it interferes in various ways with perfect filtration, but it means endless repairs to the frames, and annoying interruptions. In addition, we have all the troubles incident to the use of a complicated traveling-crane mechanism under heavy duty.

I am sure that a history of the few Moore installations in this country would exhibit a somewhat heart-breaking record of difficulties and discouragements. On the other hand, I can attest from personal experience, that the Butters-Cassel system has been a source of complete satisfaction wherever it has been installed. The Combination plant at Goldfield has run from the day of its installation with uninterrupted smoothness, without a single important alteration, and no repairs beyond an occasional overhauling of the centrifugal slime pump. The filters have never been taken out for repairs during a service of nearly a year, and will probably last until the canvas rots. There is no sloppiness in the operation, no unsightly, dripping slime-frames to move about. The system shows a mechanical orderliness and cleanliness, which, whatever its other merits may be, appeal strongly to both operator and observer.

In a word, though the Moore system may possess the advantage of requiring somewhat less power, the sum of advantages, in so far as we can estimate them, would seem to be on the side of the Butters-Cassel process, from whichever point of view we choose to take, whether that of the mechanic who is looking for the simplest mechanism, or of the metallurgist, who is striving for the best net result and lowest cost of operation.

F. L. BOSQUI.

Denver, January 15.

PRICE OF COPPER.—While undoubtedly 25-cent copper will interfere to a certain extent with new construction, it seems that at 20 cents capitalists are willing to go ahead with the electrification of existing railway lines, and therefore it can with confidence be predicted that nothing at present will cause the price to break below 18 or 20 cents per pound. While aluminum theoretically at its present price could supersede copper, yet the mechanical difficulty of handling it prevented its extensive use in transmission lines.—J. Parke Channing.

Mistakes in the Design of Mining and Reduction Plants.

Written for the MINING AND SCIENTIFIC PRESS
By S. A. WORCESTER.

It is believed that by calling attention to some of the mistakes that are most frequently noted, this article may prove suggestive and useful to mine operators. A wide observation among the many mining and metallurgical works erected in the Rocky Mountain States, lends support to the impression that many of them have been built without any more elaborate plans than a penciled sketch on the edge of a newspaper; some large plants have been laid out with a soft pencil on a piece of plank; others have been designed by technical men freshly graduated and untouched by experience. A large proportion of the mining and milling installations are designed by machinery firms, who impress upon their patrons the idea that this designing costs the customer nothing, but no very brilliant reasoning is required to make the interest of the machinery builder evident in the sale of his own machines, to the exclusion of all others, regardless of the customer's interests. Too many of the works thus designed free of cost, prove to have a practical value about equal to the supposed cost of the drawings. A few of the large mining corporations employ a force of draftsmen, under the direction of engineers of long experience and thorough education; where this is done, and sufficient time is allowed for designing, the results are apt to be good. Not many operators, however, employ mechanical engineers constantly.

Not long ago the operator of a small mine, with a 20-ton cyanide plant, decided to add a second set of rolls, to move his crusher closer to the mine shaft, and to raise his head-frame, so as to give height enough to chute the ore direct to the crusher, and save tramming. About this time he was approached by an experienced draftsman, who offered to make drawings of the proposed changes for a small sum. The operator saw that the draftsman's ideas were practical, but did not see any necessity for drawings. "You're all right," said he, "but I know just what I want. I don't need any drawings." He proceeded to build a frame, on which he set his crusher, and found, to his surprise, that a feeder had to be made to get the ore from the crusher to the rolls. He then raised the head-frame a distance which he was sure would be ample, and built his chute, and found that he didn't have height enough after all, and he now shovels the ore from the chute to the crusher. With cutting, trying, and making over, he and two mechanics spent more than two months getting into operation an arrangement that any good draftsman and constructor would have designed in much better shape and got into satisfactory working order within three weeks at the outside, with the same force of men. In another case, a mining company was substituting an electric motor for a mule, to propel an ore-car between shaft and ore-houses, and the arrangement was complete and ready for work, except the trolley. No drawing or sketch had been made for this part, but a machinist was told to make some kind of trolley. He did so, with the help of the blacksmith, and when the complicated arrangement was attached to the car, it literally 'fell down,' and refused to be of any use whatever. A second trolley was made with the same result, and a third one was finally made to answer, although it was made with so strong an upward pressure that it broke the trolley-wire every few days. Finally the wire was replaced by a rail of ½ by 1½ in. iron, which withstood the pressure. About a month was consumed, after the first start, in experiment and delays, before the trolley was finally successful, and it is still a poor arrangement. An experienced draftsman was within easy reach, and could have sketched the simple, cheap, and satisfactory trolley commonly used in traveling-crane work, at a trifling cost.

Cases like these, in which designs and drawings are entirely omitted, are of frequent occurrence in every mining camp. The plank and soft pencil layout, which I have mentioned, is usually made by a carpenter or millwright whose principal weakness is his inability to analyze and calculate intelligently the stresses in his framed structures. When he lays out a piece of work, he uses timbers of the same size he has used or seen used before, as nearly as he can remember, and if in doubt he simply makes them good and heavy. With all his waste of timber there are usually a number of weak points in his structures, which become evident when any unusual lode occurs. One favorite practice is the lavish use of 12 by 12 timbers and struts, generally in places where no justification, either practical or theoretical, can be found for anything larger than 8 by 8. In supporting floors, tank-bottoms, ore-bin sides, and slopes, etc., the value of relatively deep joists and timbers is not appreciated. The tables authorized by the U. S. Department of Agriculture, Division of Forestry, using a minimum safety factor of 6, are excellent authority and safe dependence on the strength of timber, and they show very clearly, for instance, that a 4 by 12 joist, with its 48 in. of section, is not as strong edgewise as a 3 by 14 joist, having but 42 in. of section, and that a 12 by 12 girder, with 144-in. section, is not as strong as an 8 by 16, having but 128 in. In the timber bill for a single large plant, the judicious use of relatively deep joists and timbers has saved several thousand dollars, and given a stronger construction than usual.

One of the most common structural weaknesses is the result of using built-up timbers, of one inch to two and one-half-inch plank, bolted or nailed together, for sustaining compression. I have in mind a roof of 60 ft. span, 600 ft. long, supported by trusses whose upper chords (or compression members) are made of two-inch plank bolted together, and the lower chords (or tension members) are of solid timbers spliced. Not much observation or experiment is necessary to demonstrate the weakness, sidewise of a built-up timber of this kind. Any long built-up timber, if laid on end supports and turned first edgewise and then sidewise, will show a deflection so much greater sidewise, by its own weight, as to convince anyone of its weakness. I have observed a number of failures, in trusses and other structures on this account. Solid timbers do not have this defect. On the other hand, built-up timbers are much better than spliced solid timbers for lower chords of trusses and for tension generally, for the reason that a well-nailed and bolted built-up timber has from 70 to 90% of the tensile strength of a solid timber of equal section, whereas it is difficult to splice a solid timber so as to give more than 30% of its tensile strength at the splice.

An item of still greater importance than construction of buildings and stationary plant, is the transmission of power and the arrangement of machinery for this purpose, and for repairs and maintenance. The plant having the 60 by 600-ft. roof mentioned, was designed by a young technical graduate immediately on leaving school and included, among other peculiarities, 15 ore-bins, each of which had a complete inclined grizzly bottom. One conveyor about 200 ft. between centres, beneath the bins, carried the screening to the rolls, while a second 200-ft. conveyor, in front of the bins, carried the coarse ore from the bin-gates to the crusher. An experienced designer sees at once, in this arrangement, 14 superfluous grizzlies and one superfluous conveyor, with their firs[t]

outlay and maintenance to be provided for. A sampling plant that I have in mind was built five years ago with floors about 18 ft. apart, where there is no possible object in having more than 12 ft. All floors are at least one-third larger than they should be for economical working. The entire plant is built in duplicate at a cost of nearly $100,000, yet so designed that its actual capacity is less than that of others of half its size. Every pound of ore has to be shoveled into wheelbarrows. The great height of the floors makes elevators lift material at least 50% higher than should be necessary. Much expensive handwork is done and the power consumption is high, yet we are told that no amount of argument will induce the manager to spend a few dollars for labor-saving improvements.

In most stamp-mills the principal power consumer is the stamp-battery, and one particular arrangement, which still appears in the design of new plants, has so many objectionable features as make the perpetuation of it a blunder. I refer to the type of transmission which includes a number of small high-speed motors, with the necessary belts, shafts, and pulleys for reducing speed, and which places the transmission on front-knee framing. The horizontal belts are seldom at their most effective tension, and as they have fixed centre distances they must be taken up by using belt-clamps, when they stretch. Three speed reductions are usual between small motors and cam-shafts; the friction load of this arrangement is high and the efficiency of the small motors is low. Where one motor runs two or three batteries friction-clutches are used, and I have observed that these clutches need frequent repairs in both wet and dry mills. The front-knee framing, besides being expensive, occupies overhead room that is often desirable for other purposes. I prefer, for nearly all cases, the simple back-knee battery-frame, leaving a clear space in front of the batteries; one cam-shaft for each 10-stamp battery; one slow-speed motor for 30 to 50 stamps, belted to a line-shaft running beneath the battery floor; cam-shafts put in motion by tightner-pulleys on the slack side of belts. This arrangement is simple and compact, its friction-loss is low, and the belts can always be given just the right tension and will run by long periods without taking up.

In favorable contrast with such ill-planned plants as have been mentioned, there is occasionally found an installation that has been designed by an experienced engineer, technically educated, and having no business connections with manufacturers or agents. Such a constructor usually demands plenty of time and a good price for his work, and if his only interests are his professional reputation and the agreed compensation, the employer is apt to be benefited by the outcome. I have in mind a plant that was erected about two years ago. The general manager sent a full description of the conditions to a large number of manufacturers, inviting each to state what forms of apparatus he would recommend for the purposes indicated, and to submit quotations for such an installation. Each manufacturer replied, advising some form of equipment for which he had patterns and drawings on hand. The manager, dissatisfied with their proposals, engaged a mechanical engineer to design a special installation. After getting necessary measurements and other data, the engineer made five or six preliminary pencil drawings, outlines of different general arrangements for the plant, each of which seemed to have some special advantages. These preliminaries were then minutely compared and their relative advantages discussed in consultation with the manager and superintendent, and the one was selected that possessed the largest number of good points. This arrangement was then carefully modified so as to gain as many as possible of the merits of the other plans. Detailed drawings and tracings of the machinery and construction were then made, every needed dimension being shown and the number of pieces and material for every part being indicated on the drawings. These were then accurately checked in every dimension, letter and figure, by another draftsman. All calculations made in the process of designing were also carefully checked in every dimension, and after any errors had been rectified, six full sets of blue prints were submitted to manufacturers for bids. Full specifications were also written, itemizing material and workmanship in detail, including complete erection and testing of machinery by builders before shipment, etc. The highest tender received for this proposition was found to be lower than any of those made for the plants suggested by machinery concerns. The highest bid made for the drawings was 50% greater than the lowest and this difference was sufficient to pay the engineer's fee several times over. While nicely adapted to the local conditions in every detail, and making use of every up-to-date device for saving labor that could be applied to advantage, this specially designed plant made an actual saving of more than 50% in power over the best of the designs first offered. While this is probably an exceptional case, it suggests forcibly the value and importance of the work of a competent and unbiased expert. As a rule far too little time and expense are allowed for design and preliminary work, by operators of moderate sized mining and metallurgical plants, before beginning construction. They fail too often to realize the immense difference between the cost and time involved in construction and experiment on paper and the same operations in actual materials. The designs for an installation of any magnitude should not be approved until they have been thoroughly discussed by the manager or superintendent, with his responsible assistants, and all of their suggestions given due weight.

WATT-METER DIALS.—In reading these the beginning should be made with that having the lowest capacity, writing the result from right to left. In this way error due to reading pointers near the zero mark will be eliminated. Often it is common practice to read from left to right, which entails the necessity of looking at the next figure to the right before recording a digit, making an awkward proceeding, with a liability of error. Practically all meters in general use today are watt-hour meters, the dials registering the use of electrical energy in watt hours, which term is electrically defined as a current of one ampere flowing under the pressure of one volt for one hour. An electrical meter is an electrical motor, the speed of which depends on the amount of energy flowing through same, and should not register when current devices are not in use. They do register, however, when over-compensated or too finely adjusted to overcome the friction of the bearing, which condition is called 'creeping'—often due to the change in strength of the two permanent magnets placed in the meter to have a retarding effect on the speed of the disc.

ORDINARY business precautions are unfortunately often put aside when one comes to deal with mines. An otherwise smart business man, who drives a hard bargain in his own particular line, will frequently be found to part readily with money on the representations of a comparative stranger, without taking the ordinary precautions of making personal inquiries or getting the advice of a suitable man, should he lack time to investigate or knowledge of mining to enable him to himself form a correct opinion.

Dredging and Horticulture.

Written for the MINING AND SCIENTIFIC PRESS
By D'ARCY WEATHERBE.

Much has been said and written since dredging commenced in earnest in the Sacramento valley on the question of the destruction of the land by rendering it unfit for future agricultural purposes, chiefly fruit culture. A large portion of this matter, particularly that which has appeared in certain popular magazines, is, to say the least, misleading. Efforts have actually been made to restrain companies from carrying on their operations. No apology, therefore, is needed in referring to this subject. Care has been taken to obtain the facts from persons interested both in dredging and in the culture of fruit, and the following brief remarks sum up the results of such investigation.

Oroville is the most important district in this connection and here the possible dredging lands, including what have already been worked, will probably cover about 6,000 acres. Of this tract less than 400 acres has been planted in fruit and though about 1,000 acres of the remaining portion, at an outside estimate, might with irrigation be used, it is ground of a poorer quality, requiring much annual expense in water and cultivation, and it is extremely doubtful, judging by the prevailing conditions, whether it would ever be used for this purpose. Of the 400 acres mentioned, 150 acres are included in the Leggett vinery, which for several years has been infested with the practically fatal phylloxera and probably $300 per acre would cover the amount on which it would pay, say, six per cent per annum, for horticultural purposes. Similarly, the Wilcox peach orchard, covering 50 acres, produced an average of one crop in three years, and might provide an income of six per cent on $100 per acre. The Gray peach orchard of 20 acres would pay a fair rate of interest on $200 an acre. The Gardella tract is a fine piece of land of 40 acres and peculiarly adaptable for the production of vegetables as well as fruit, and for market gardening generally, and would possibly pay six per cent on $1,000 per acre. The remaining portion cannot be valued at over $50 per acre, and the whole 6,000 acres would not represent at the outside an invested capital of over $250,000. Moreover, it is a well-known fact that most of the ranches in this district were mortgaged.

If we say that the district will yield on the average 10c. per yard net profit and averages eight yards in depth, both fairly conservative estimates, then over 23 million dollars net profit will be produced and if invested in the State at six per cent, will produce an annual income of over $1,380,000 instead of the paltry revenue of $15,000 per year, which the land produced before. Besides this, for a long period a large population will be employed in the district and at the end of the period of operation another 20 million dollars should have been expended in labor and machinery.

On the Yuba the question of interference with arable land does not arise.

At Folsom most of the bench land has been worked over before by gravel miners, who left a large proportion of it in such a condition that it is unfit for cultivation. Of the 6,000 acres available for dredging, probably not over 5% has been planted and little more is available for planting, the chief product being grapes. This land is owned by the Natoma Vineyard & Winery Co., and the population it actually supports is small. A comparison similar to that at Oroville might be made in regard to this district, which would probably show even less favorable results for those busybodies and other uninterested parties who have attempted by unwarranted agitation to raise a storm in a tea cup. If the question be really pushed to an issue, an excellent solution would be to invest enough of the proceeds of the dredging operations in the filling of the now worthless tule lands (of vast extent in this valley), so that an acreage equal to that destroyed might be put into cultivation. This, however, would probably be an inconsiderable sum, particularly as the sale of such land would, of course, revert to the dredging companies.

After dredging, the land is covered with stack piles, containing boulders and pebbles, the fine material being hidden 6 to 15 ft. below. In regard to the reclamation of land in this condition, certain experiments attempted by Mr. J. H. Leggett, at Oroville, produced interesting results. Eucalyptus of both the 'blue' and 'red gum' variety and some fig trees were planted on the stack piles, and alfalfa grass is also growing. The trees, when set out, were only about 10 in. high. In the case of the largest tree, 19 ft. of growth was attained and of course this will increase in greater proportion with time. Some of these trees were planted directly on top of the highest ridges, 15 ft. above the original surface, and Mr. Leggett states that one cannot dig a hole at any of these highest points more than two feet without getting moisture, even in the driest time in summer. The volcanic ash that forms the bottom of the digging and the material of certain clay bands is often carried over the stacker in lumps and disintegrates on being exposed to the air so as to form the soil necessary to growth. The alfalfa roots were accidentally thrown up by the dredge and the grass seems to do particularly well. Absolutely no care was given to the trees or grass from the time they were set out.

Nevertheless, it is not considered with the stack piles in their present condition of irregular surface that a profitable horticultural industry could be built up. It has been suggested that the piles might be leveled with huge scraping rakes run by electric power, and in this connection an instance of the present cost by hand for leveling at Oroville is given. Near the town the original owner of a tract that was dredged agreed to put the ground in a suitable state of cultivation if given to him. He leveled one acre and covered it with one foot of soil and now has a productive garden; the total cost of levelling and covering being $250.

Ground that was dug by the single-lift dredges (with the long sluice on a pontoon to the rear) was left in as good condition as before dredging commenced, that is, for agricultural purposes. It is perfectly flat and the fine tailing is mixed with the pebbles and boulders, and in many cases is altogether on top. Instances of this may be seen where the Continental dredge operated at Oroville, and at Folsom a particularly good example is afforded by the work of the *Ashburton*. This boat originally employed a long-sluice method, but changed to the ordinary screen and tables, and the contrast between the two results in stacking may be observed on the same property, the work having been done by the same dredge.

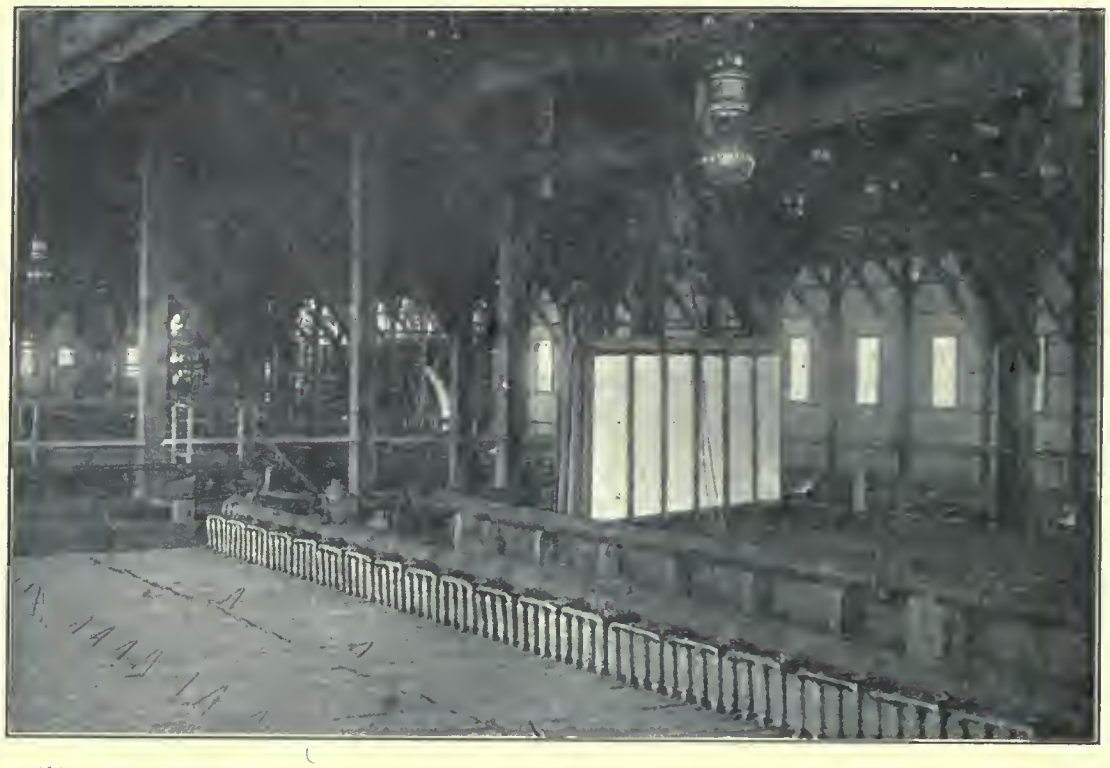
At Folsom the stack piles are to become a valuable asset in the hands of the enterprising management of the Folsom Development Co., who are installing a rock-crusher plant and the product is to be used in railway and road ballast, and for concrete work.

IN drilling with machines it does not pay to overload an air-compressor with too many drills, or to use a main pipe so small as to reduce the air pressure materially. Experiments show that a drop of pressure from 75 to 45 pounds will reduce the length of hole drilled by more than 50 per cent. Great care should be taken to have no leaks in the pipe-line, especially in the hose and couplings.

The Butters Filter.

Written for the MINING AND SCIENTIFIC PRESS
By MARK R. LAMB.

The accompanying illustration shows a Butters' filter with the necessary tanks and pumps. The filter is extremely simple and consists merely of two sheets of canvas sewn to a core of cocoa-matting. These resulting leaves or cells are supported by a wooden strip at the top and by a frame of half-inch pipe at the sides and bottom. The cells are connected by short nipples and hose to the vacuum-drum. When the filter-box is filled with pulp, which has been previously agitated with solution, the vacuum draws the solution from the slime, leaving the latter on the leaves in the form of a layer. This layer is made from 0.75 to 1.5 in. thick, depending on the class of slime. During the time the slime-cake is being formed the filter-box is kept full of pulp, the additions replacing the solution withdrawn through the cells and keeping the slime agitated.



The Butters Filter at Work.

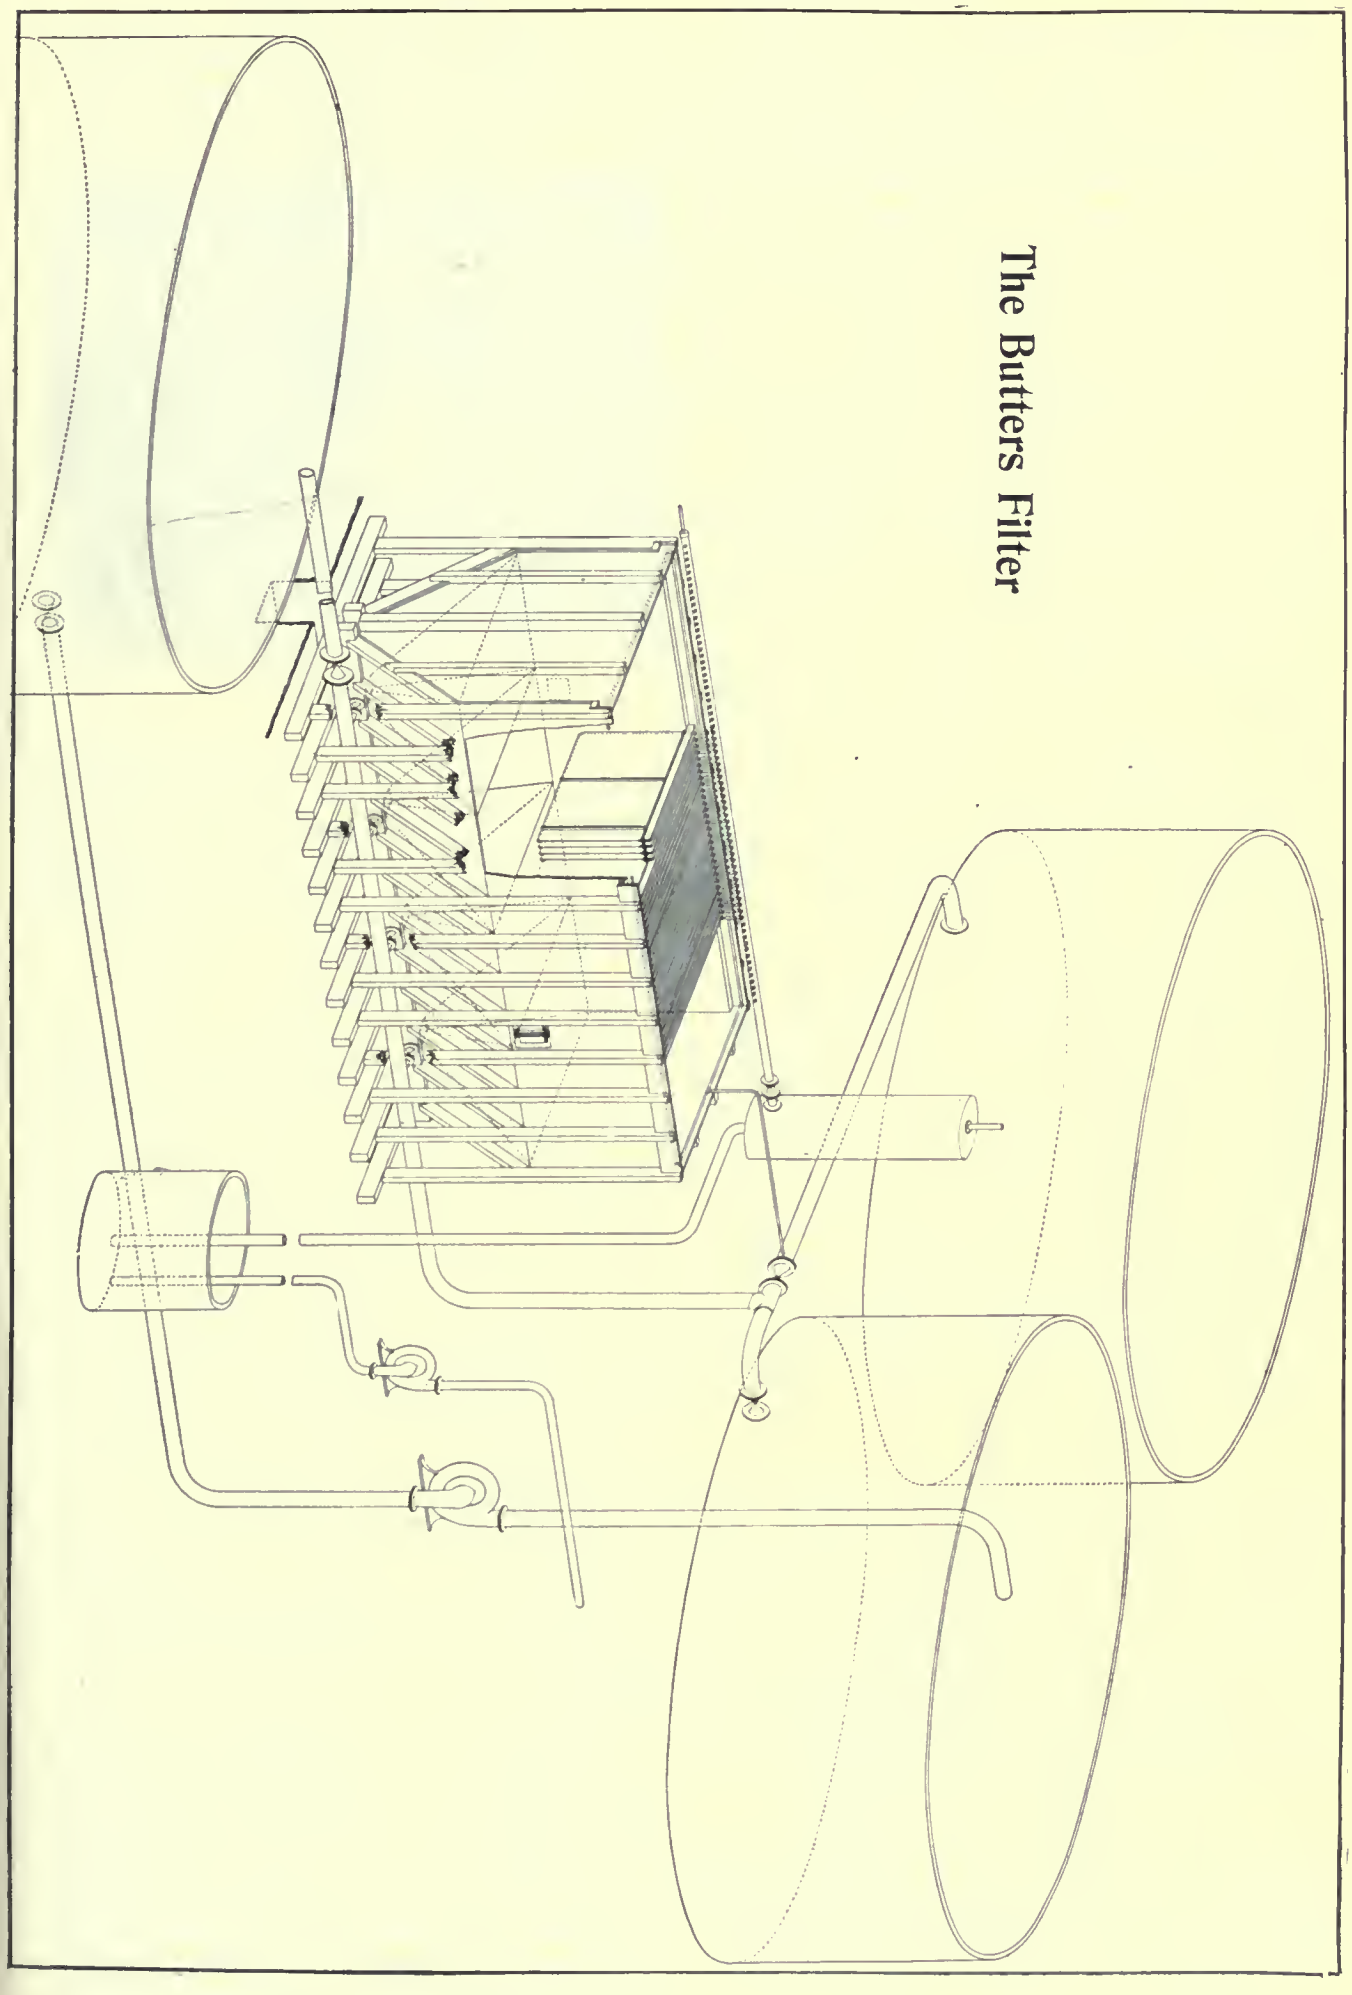
The layer forms continuously and, as would be expected from the nature of the operation, its thickness varies from top to bottom, depending upon the permeability of the stuff deposited. In other words, the slime resulting from all-sliming, which contains fine sand, forms a thicker layer on the lower portion of the leaf than on the upper. This thicker part is more permeable and is washed in exactly the same time as the thinner but denser upper part.

After the layer of slime has attained the desired thickness, the pulp remaining in the box is drawn off to the pulp-sump, and the box is filled with water. This water is drawn through the slime until the latter is thoroughly freed from solution and metal in solution. The vacuum is then broken and clear water introduced under slight pressure into the interior of the leaves. This dislodges the slime which is discharged from the hopper bottom through a gate-valve. Where it is desirable, a large portion of the water remaining in the box can be withdrawn before the slime is discharged, and if water is very expensive the slime can be dislodged with compressed air and trammed from the filter-box. The small centrifugal pump returns the pregnant solution to zinc or fume or electrolytic precipitation boxes. The large centrifugal pump returns the excess of unfiltered slime to its storage vat. All valve-stems are extended to the operating floor, which permits one man to treat almost any tonnage. The canvas does not seem to deteriorate, one set having been in service over two years. The lime used in neutralizing acidity appears to protect the fibre. When this calcium carbonate accumulates sufficiently to delay operations, it is removed by subjecting the leaves to a bath of 2% HCl.

The filter-box may be made either of wood or iron, as may seem advisable, depending on the locality, costs, and freight. Where the site does not permit of filling and emptying the box by gravity, the pulp is circulated and transferred by the pump. The valves in such a system are all placed near the pump and controlled from the operating platform above mentioned. The wash attained by the filter is notably perfect and is accomplished by the use of a minimum of water.

Slime is now being treated, resulting from the milling of Tonopah ores, which it would not be possible to treat by decantation, and for which a filter-press installation would be prohibitively expensive, as well in first cost as in labor and power. This filter combines the best features of the Moore, Butters, and Cassel patents and will be the means of extracting precious metal from slime not amenable to treatment by any other method, as well as from sand now treated by percolation, but which will be ground much finer and treated by agitation and filtration.

MEN are often heard to speak of the money they have made or lost in mining. On making closer inquiries we generally find that the losses or gains were not made in mining, but in speculation, the profits frequently coming out of other men's pockets instead of out of the ground; while the losses are often considered as the difference between the highest quotation during the time the operator held them, and at which they might have been sold, and the price at which they were eventually parted with.



The Butters Filter

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

Where the validity of the location of a mine had been unchallenged for more than five years and up to the beginning of an action in ejectment, and where it appeared that the original locators were absent from the country the court decided that the certificate of location created a presumption of discovery of mineral and of a valid location. The court said that especially should such a presumption be indulged in a summary proceeding instituted at the beginning of a suit where the granting or withholding of an injunction depended upon facts presented by affidavits and which rested largely in the discretion of the trial court, and where a subsequent locator attacked the title of the prior locator, or that of his successors in interest. The trial court committed no error in denying the injunction applied for, on the ground that the location notice failed to mention the discovery of gold on the claim, and that such conclusion was aided by the affidavit of the complainant, who had a lay on the claim and who stated in his affidavits that pan had been discovered by him and his co-lessees and that "gravel on said claim is exposed on the surface on many parts thereof and carries fine gold throughout, so that panning from the surface is easily done and colors are easily found."

In the same case it was decided that a location notice was sufficient which described the claim by metes and bounds and a reference to stakes set in the ground, and added that the claim "lies about one miles from Anville mountain, in a southeasterly direction." The defect of the notice was claimed to be that it pointed out no particular portion of Anville mountain as a beginning point. While the court was not advised of the shape or dimensions of the mountain it stated that in the absence of evidence to the contrary, it would assume that it was a recognized landmark.

Vogel *v.* Warsing, 146 Fed. 949.

A part owner of a placer mining claim brought an action to recover possession of the interest of his co-owner, claiming a forfeiture for failure to pay the amount of assessment work done on the claim. The issues presented for trial were whether assessment work of the value of $100 had been done, and whether the requisite notice of contribution had been served as required by statute. The law required $100 worth of work. The Court refused to order a forfeiture, where it appeared that such part owner simply went on the claim and did thereon what he considered $100 worth of work; it was not sufficient to entitle him to maintain his action that he made a bona fide attempt to comply with the law in order to obtain a forfeiture of his co-owner's interest had no part in the questions to be considered by the jury in aid of the proof that he did or did not do the requisite assessment work.

McKay *v.* Neussler, 148 Fed. 86.

The statute of Iowa provides that every laborer or miner who shall perform labor in opening, developing, or operating any coal mine, shall have a lien on all the property of the person, firm, or corporation owning or operating such mine, and used in the construction or operation thereof, including real estate, and personal property, for the value of such labor, to be secured and enforced as mechanics' liens are. It was held that this statute did not give a lien on the mining property of the owner in favor of the employees of a person operating the mine as a lessee, as the word 'or' between the word 'owning' and the word 'operating,' as used in the statute, could not be construed to mean 'and.'

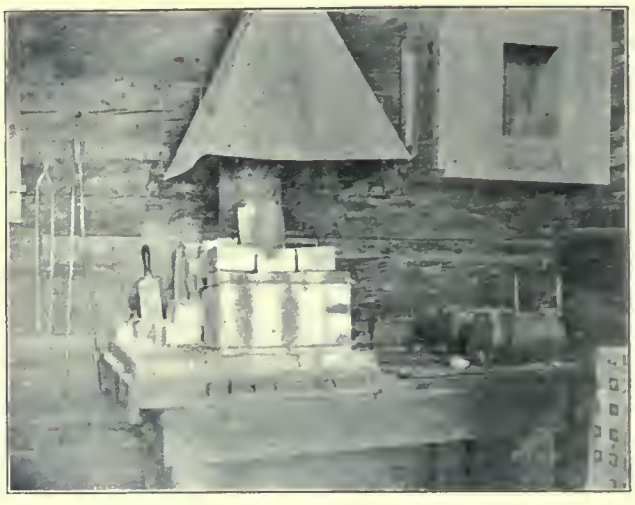
Caster *v.* McClellan (Iowa), 109 N. W. 1,020.

A person who performs services which consisted in caring for mining property in the way of paying taxes thereon, listing it, and keeping off trespassers, was held not to be entitled to a lien which followed the property in the hands of the purchaser.

Morrison *v.* New Haven &c. Min. Co., (N. Car.) 55 S. E. 611.

A Simple Assay-Furnace.

The illustration shows an extemporized crucible furnace erected at Cornucopia, Oregon, in 1897. Heavy snowstorms completely shut off the camp from communication with the railroad, and supplies ordered were held at the roadroad for weeks. The construction is simple, as illustrated. Eight ordinary fire-bricks were placed on end, surrounding one brick that served for a floor. Fire-clay was used as a cementing material, and the furnace clamped together by ⅜-in. iron rods, with an eye on one end and threaded for a nut on the other, such as could be made in any mine blacksmith-shop. Three fire-bricks were used as a cover. A hole was chiseled out for the admission of a gasoline burner.



A Simple Assay-Furnace.

Roof Support.

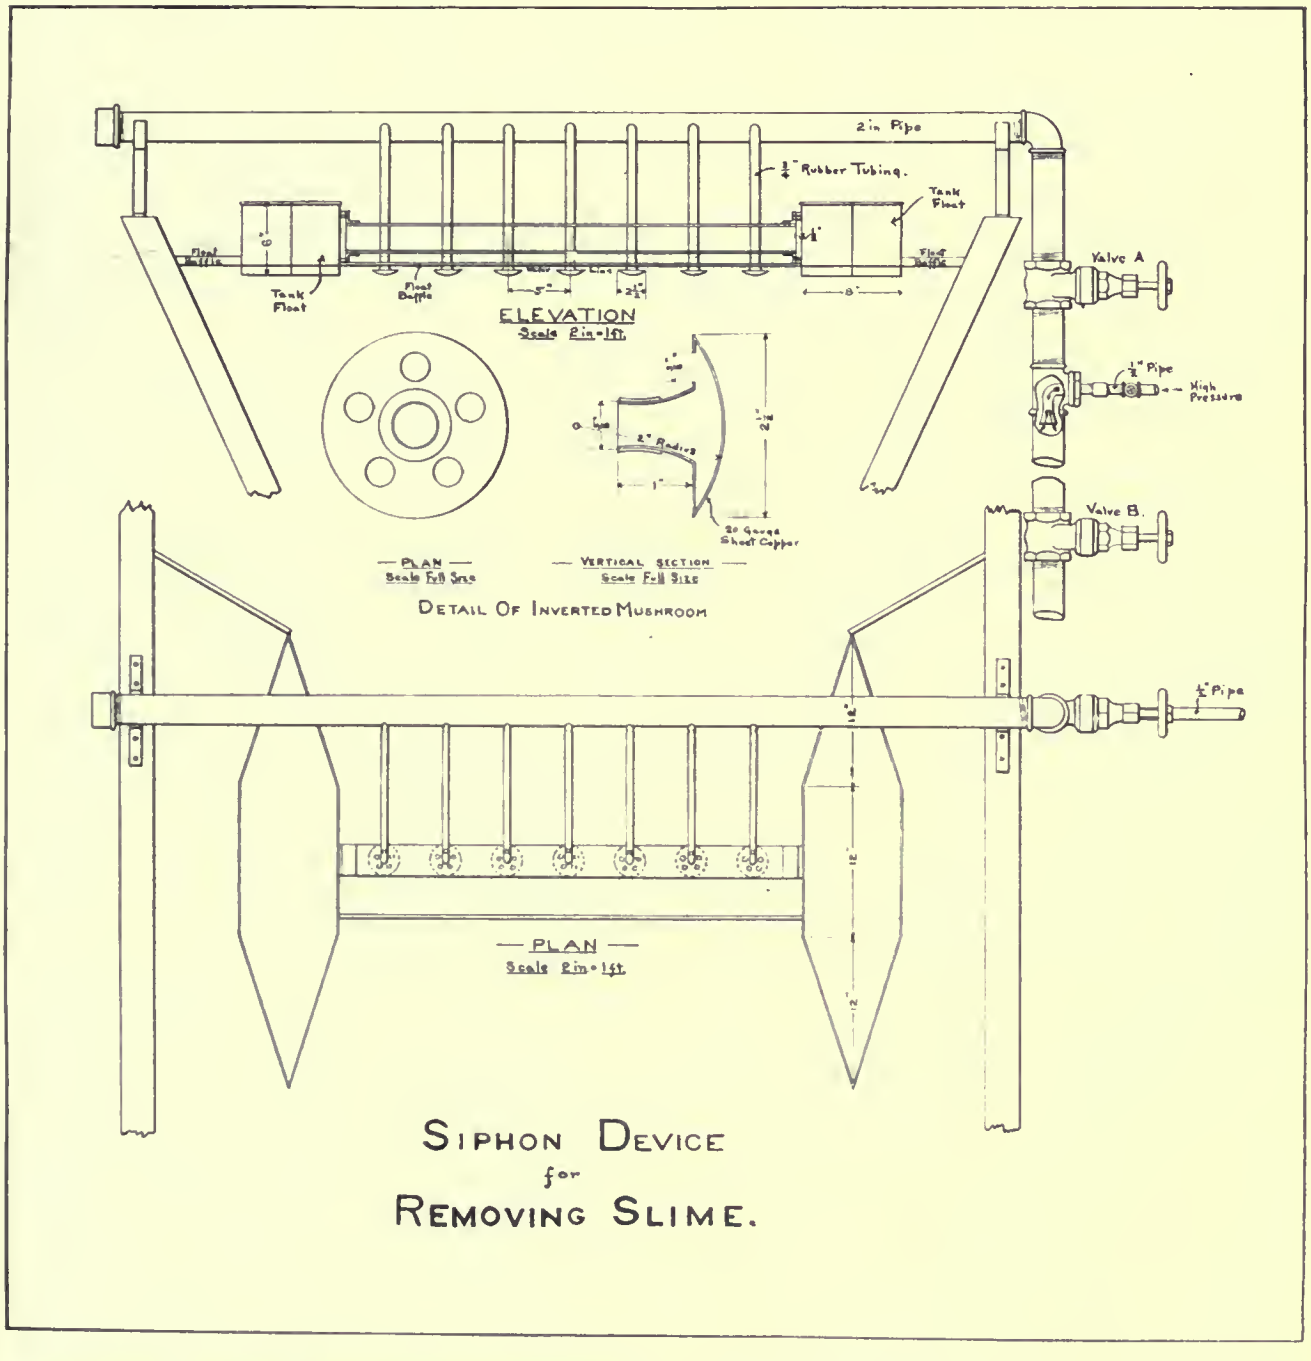
An economic method of supporting the roof in main haulage-ways is practiced in French collieries. Old iron rails are bent slightly and placed transversely across the drift so as to form a low arch. The ends of these are supported on dry-stone walls built up at the side of the drift, sill-plates being laid to distribute the weight. These rails are arranged at intervals of about one to three feet, according to the character of the roof. Across these a number of rods, having their ends turned down, are placed longitudinally to form the lagging. Iron bars, one inch square, may be used for this, but in practice a great deal of scrap iron can be made up by a blacksmith into suitable material. In this system nothing is fixed until the roof settles down, and all parts are interchangeable so that, in the case of a cave, repairs can be completed very quickly and all material used again. Where the system is feasible and good roads are required, the cost will be found very low, as most of the material can be gathered up round any large mine or bought cheaply. A heavy roof can be readily detected by the bending of the lagging rods, a fact which gives this method a great advantage over that of the systematic use of iron girders.

SECOND-HAND MACHINERY is seldom the bargain some purchasers suppose; it has often been discarded by more advanced mines; it can seldom be given a run before purchase, and not being new has no makers' guarantee. Frequently the machine is in some out-of-the-way place, so that it costs more to dismantle, pack, and transport it to a new site than it is worth; small parts get lost and broken, and it generally costs more to erect than a new machine. The purchase of second-hand boilers is almost always false economy, unless one knows they have been properly treated and looked after.

A Siphon Device for Removing Floating Material.

Written for the MINING AND SCIENTIFIC PRESS
By EDWARD S. WIARD.

The device described and illustrated in this article was used by the writer in a mill in northern Idaho to remove particles of floating galena from the surface of the water in a long V-shaped tank, distributing thickened pulp to a number of Wilfley tables and vanners. Owing to the manner of mining, the milling ore contained an extraordinary amount of wood, causing more than the usual trouble of stopping up plugs and clogging the riffles of the Wilfley tables. An examination of the floating material showed it to consist largely of fine bits of wood to which had adhered scaly pieces of galena; the adhesion of the two being possibly assisted by a film of grease on the wood. The galena was rather richer in silver than the regular run of concentrate; tests with silver-leaching salts and an examination with the microscope showing the increase over the normal proportion to be due to tetrahedrite. This mineral was in minor amount in the ore as it came to the mill, the predominant silver mineral being argentite. A little galena was lost by greasy flotation. The undressed ore contained large amounts of spathic iron and the tank-water was slightly acid. Apparently, the top layers of the water in the tank were perfectly clear but the insertion of a baffle-board would cause a black scum to dam up behind it, constantly being augmented, and spreading over the surface of the water. The galena could readily be separated from the wood by agitation; after shaking a portion of water and scum in a beaker, the wood would rise to the top and the galena settle to the bottom.



SIPHON DEVICE
for
REMOVING SLIME.

The water from the siphon was used to wash down the concentrate formed by the vanners. Clean water was scarce and, it being necessary to make a concentrate high in lead, it was not possible to use the overflow water of the tank for sluicing purposes. The overflow of the tank contained a noteworthy quantity of fine matter, which was further settled on the lower floor.

The device, herewith illustrated, is suggestive of a means of reducing the volume of water flowing through a tank. The slime and sand treated in the mill under discussion were rather free from clayey matter and the surface water but a few feet from the feed end of the tank was very nearly clear. The device floated in the water about two-thirds the way from the feed end to the over-

flow end, but it would have been possible to have placed it much closer to the feed end of the tank and obtain water free from low-grade slime. For the purpose of merely removing comparatively clean water, a number of the devices could have been used.

The two float-tanks should properly be made of thin sheet aluminum. My floats were made of No. 30 sheet iron heavily coated with bitumen. At the top the sides are bent over a heavy wire, bent to the shape of the tank, to give stiffness. The rubber tubing used was ¾ in. outside diameter, with walls 3/32 in. thick. The tubing should be thin-walled, so as not to interfere with the free vertical movements of the floats. The bracket between the floats, supporting the tank-end of the tubes and the inverted mushrooms, is made of light strips of wood stiffened by four little angle-irons in the corners. These can be quickly made and bored and countersunk for wood screws by the mill-blacksmith. Care should be taken to make the upper row of holes in the bracket vertically above the corresponding lower ones. These holes should be of a little less diameter than the tubing; the tubing will then be firmly held and yet adjustable. The inverted mushrooms or strainers are made of No. 24 copper plate. With the form of strainer used, the pull due to the siphon action drew the top layer of water downward and in from the sides firmly and gently. With a simple tube in the water a current would be created from the bottom of the tank that would stir up the low-grade slime below the upper layers of water. The nipples on the 1½-in. pipe are short pieces of pipe screwed into the sides. The tanks are prevented from moving from their positions by strings fastened from their points to the nipple pipe; they are not shown in the drawing. The little strips of wood from the points of the floats to the sides of the tank are in the nature of baffles to cause the floating material to converge toward the mushrooms and prevent its passage between the floats and the sides of the tank. A similar strip floats behind the mushrooms to prevent floating material from passing by them.

The siphon device is started by opening the valve from the high-pressure supply; after it is started, the valve is closed and regulation is effected by the valve *A*. To avoid a climb to the tank, a second valve (*B*) was placed on the vanner floor for starting or stopping the siphon.

PLATINUM was first found in the present Republic of Colombia (then a part of the Spanish boundless domains), about the year 1735. "Not knowing its utility, it was thrown into the sea, so that it should not be used to adulterate silver." It was named *platina* (little or inferior silver). Besides having it thrown away into the sea, the Spanish Government enacted a law forbidding it to be exported in any form from tropical America to Europe, as its weight had already been seized upon by some false-moneyers (coiners) in Barcelona and Madrid, to put spurious 'gold' coin in circulation. While silver and copper, if used in base gold coin, would betray themselves by their weight alone, an alloy of platinum and copper, covered with a thin coating of gold, would not only deceive the eye, but also the most sensitive touch.

IN a cooling layer of fused rock, the smallest number of fractures that can be opened about a point on its surface by equable contraction is three, and hence this number is easiest to make; and since three such lines symmetrically placed make angles with one another of 120°, the hexogonal prism, more or less regular, is the most common form of the resulting column. This columnar structure is most common in basaltic rocks, but has also been observed in phonolyte obsidian, and other volcanic rocks.

Spanish-American Mining Terms.

Written for the MINING AND SCIENTIFIC PRESS
By H. E. WEST.

One reads nowadays in the current mining press of terms familiar enough to those conversant with the Spanish-Americas, but still foreign to many readers, and it may not be amiss to mention a few of the more common words and phrases.

Many such words have been borrowed and are in daily use in mining communities the world over; as, for instance, who does not know of *bonanza*, *patio*, *arrastre*, and the like.

In Central America the native is called a *mozo*. In some republics he is compelled by law to work. The services of a native are said to be 'compromised', or he is *compromiso* when he owes any sum of money that he may have borrowed from an obliging *finca*, or coffee ranch, and he is compelled to pay such a debt by service, not being enabled to liquidate, unless with the consent of the creditor, which is very rare, as labor is scarce and illy paid. Once in debt the *mozos* remain in debt, and they often leave the mines earning a good wage for a mere pittance. This seems an iniquitous system.

Each miner is given a *boleta*, or ticket, numbered, which must be shown at the *liquidacion* of the *cuenta* or account, every *quincena* or fortnight. The miner is called a *barretero*, that is, one who works with a *barreta* or bar. *Minero* applies to a mine owner, or to a foreman, the workmen being known as *operarios*. In Mexico we have the *peones* or serfs, poor Indians who know little else but work and often cannot understand the Spanish language. The *barretero*, of conrse, is above this class, as some centuries of mining have raised a fairly efficient, if a somewhat rough, class of men.

A *gambuchino* is a prospector. A mine is said to be worked *en partido* when the miners retain a part of the ore won in lieu of payment, and is identically the same as the Cornish 'tribute' or 'leasing'; a certain proportion of miners the world over always work on this system, and often make very substantial returns. It calls for a certain kind of ability that takes time to acquire and such men deserve all they ever get.

In Mexico, under the old laws derived from Spain, mines were held in *barras*, or one twenty-fourth part. One *barra*, often held by some of the old mining families, in a rich mine, would constitute a veritable fortune. The shares were of two classes, *aviadoras* and *ariadas*. An *aviador* is one who subscribes working capital for a mine—assessable shares, in other words; *ariada* shares, on the other hand, were free shares, subscribing nothing but participating in the profits—that is, non-assessable shares. The modern terms are *liberadas y pagadoras*—free and payable. There is a distinction in respect to the division of the profits between these old and new terms. The addition of *y Anexas* implies the mine named and its subsidiaries—for instance, in Pachuca, you will see quoted 'San Rafael y Anexas', which includes San Rafael, Sorpresa, and Soledad, and the share carries a partial dividend from each, while 'San Rafael, Aviado', pertains to that one mine and carries the full dividend declared; and the same applies to the subsidiary companies, all worked as one company, but with their ores credited to each mine, and the profit or loss arrived at separately.

The claims being pegged to all parts of the compass, more often than not there is a fraction between, called a *demasia*. This *demasia* is equally divided between the contiguous claims by a vertical projection of the dividing line.

'Denouncing' a claim is a term used for the application of properties originally taken under the old laws

and almost all property has been denounced at one time or the other, and abandoned time and time again. *Antiguas* applies to the old mines, the workings of which testify to the work done in bygone days. These *antiguas* are scattered from Texas to Panama, and a great number are being opened up at the present day.

In Central America ore is universally known as *brosa*, and waste as *tierra* or *atierres*, similar to the Cornish 'attle' or 'addle'. In Mexico ore is *metal* and waste *tepetate*. In Central America this term was used for a 'hard-pan' at surface, very similar to the *caliche* of South America. *Terreno* is the dump. A vein is *veta*. *Veta ramal* is a branch vein; smaller veins or droppers are *hilos perdidos*—lost threads. *Veta recestada* is an inclined vein. *Rumbo* is its strike. An adit or level in Central America is *taladro*, literally a drill; or, at times, *tunel*. *Socavon* is universal in Mexico. *Socavon crucero* is a cross-cut, the latter alone being adequate in Central America. *Respaldo* applies to the walls, *alto* or *arriba* and *bajo* serving for the hanging and foot-wall respectively.

Caballo is the equivalent of a 'horse', sometimes *puertas*. *Pozo* is a shaft, while in Mexico *tiro* is used; and a *tiro* applies to a shot in the former country. *Chimenea* is a raise. *Comida* is a stope—eaten-out ground after the idea of the Cornish 'gunnies'. A stope is a stope in reality when in the act of stoping—hence the Cornish distinction, which appears correct.

Bolsa is a small pocket of ore. *Bonanza* is a shoot of ore. *Borrasca* is barren ground. *Escalera* applies to the 'chicken-ladders,' or the notched poles, found wherever the Spanish language is spoken, and sometimes where it is not. *Tanates* are the bags on which the *tanatero* packs out the ores by the *escalera*, and the writer has seen this peon-packing in modern times both underground and at surface, with modern equipment lying idle—claiming an economy. *Peones* are certainly wonderful packers, and you may depend, if humanely possible, and sometimes when it is not, that a *peon* will get his job on his back—irrespective of any physical properties it may possess.

Carga is a mule-load and *cargadores* are the muleteers. *Malacate*, properly a 'horse-whim', is applied to all hoists. *Malacate* is applied to a rope in Nicaragua. *Bodega* is a store.

It is remarkable with what little knowledge of the language one can carry on work in Spanish countries. I am reminded of one good old fellow who once worked for me in Nicaragua. He was very deaf and well up in years. One day he remarked to me: "Somehow or other I can't catch on to this 'ere lingo." However, he progressed, and one day I heard him sing out "Hi, Jose, go to the *dago* and fetch me *macarthy*." These were about the only two words he ever really mastered. They refer to the two terms last quoted, in case there should be any doubt. He got his rope just the same.

Just how *santiago* should designate a 'Jim-Crow', or why the latter is considered fitting to such a useful article as a rail-bender, is beyond my ken.

Those living in New Mexico, Texas, or the Border, do not need reminding that *aparejos* and *alforjas* apply to a pack-saddle and saddlebags.

In milling parlance treating an ore is 'beneficiating'—*beneficio* meaning to treat an ore to extract its metallic contents. *Haciendas de beneficio* are treatment plants. *Patio* is the court paved with close-fitting blocks in which the patient mules tread the silver ores in the classic metallurgical process that is now passing rapidly away.

Since the fifteenth century, when Bartolomé de Medina in Pachuca, discovered amalgamation, practically all the vast silver production of Mexico has been won by the *patio*, and I remember only in 1903, at Guanajuato, seeing many large *haciendas* in vigorous work. Today the *mazos* displaces the *rastron*, or Chilean mill, and the *arrastre*, and have driven the mules, I was going to say, from, rather to, the field. It looks possible that soon no more will the *magistral*, or roasted copper ore, be incorporated in the *torta*, or pile; nor the patient *ensayador* make his *tentadura*, or horn-spoon assay, and the *planchas* will be won by cyanidation, or the modern amalgamation plant.

Petanque is applied to tetrahedrite, and *rosiclara* to ruby silver; *negrillo* to the black silver sulphide; while gossans or oxidized ores are *coloradas* and sulphides, *negras*.

What's in a name? we often hear. Much, both on the stock exchange and to the Mexican holder. These are not by any means akin in sentiment, for the former wants something that will 'catch on', as 'Sallies', 'Kangaroos', etc., while such names as 'Santa Maria de la Paz', 'Espiritu Santo', 'San Felipe de Jesus' imply a dedication and a prayer for the success of the venture to the particular saint. For religion enters strongly into the everyday life of the Mexican miner, and even today, in Mexico, altars and shrines are all but universal in the mine. Religion is woven into the warp and woof of the Indian life. The Catholic churches in Central America have embodied into all their important festivals the propensity for pyrotechnic display so loved of the Indians, so that in the early morning, and throughout the day, the city appears besieged by the number of day-rockets that are mingled with the celebration.

When a miner made a strike he usually celebrated by building a church, as the Borda church at Tlalpajahua, or gardens, as at Cuernavaca; or even solid silver altar-rails, as at Guadalupe. Alvarado, of Parral, a worthy man, but a very maligned one, built a palace.

It is not unusual for priests to officiate in the blessing of some new piece of machinery. I remember, not so many years ago, reading of the blessing of the large pump at the Difficultad shaft of the Real del Monte Co., and who shall say that either the mine or the *peon* is the worse either for a title that is full of expression to him or for a rite that through centuries of training has become as natural as the blessing of his daily bread.

Mining to the Spaniard is not merely a business proposition necessitating maximum rush and profits. A good mine is a charge to be carefully nurtured and handed to posterity. The spirit of modern mining—the maximum profits consistent with the shortest life—is an abomination to his soul and altogether foreign to his temperament.

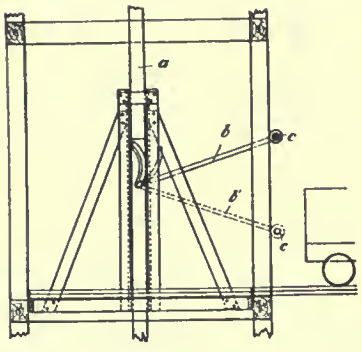
Sometimes one cannot but feel regret that all this is passing; the mines are falling day by day into the hands of the 'gringos'. Let them all go; yet many of the Spanish terms, indelibly carved on the annals of an illustrious past by a great mining nation, will outlive its mines and people.

THE kaolin, or china-clay of Cornwall and Devon, exists in irregular deposits consisting of granite decomposed in place, not by atmospheric agencies, as is often stated, but far more probably by hydrofluoric acid brought up by deep-seated fissures. That the decomposition was due to the veins or fissures seems evident from the fact that the altered rock occurs in bands adjacent and parallel to them. Where the veins are numerous a large mass of china-clay may be found, extending for a width of a hundred or more yards. The depth to which the alteration of the granite continues is quite unknown. The veins are often tin-bearing, and workings for tin have led to the discovery of china-clay; indeed, the two minerals are often worked together.

MINING AND METALLURGICAL PATENTS.

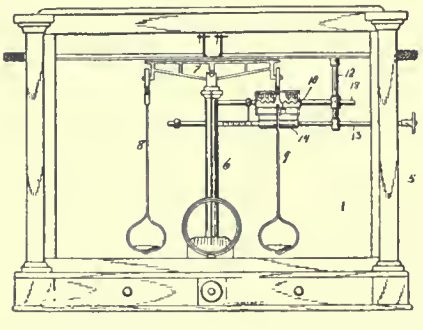
Specially Reported for the MINING AND SCIENTIFIC PRESS.

MINE-SHAFT.—No. 841,416; Josef Mika, Bottrop, Germany.



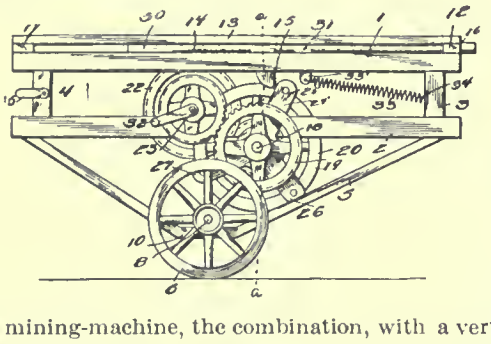
In a mine-shaft, means for closing the opening of the shaft, comprising, in combination, a rod c destined to close the shaft-opening, and two rods, b, b' pivotally mounted in the two track-ledges of the shaft and connected at their front ends by said rod c and provided at their rear ends with projections adapted to project, when the shaft-opening is held closed, beyond the track-ledges and to be pushed aside, when the shaft-opening is being opened, into slots provided in said track-ledges of the shaft, and thus to be lifted together with said rod c for opening the entrance to the shaft, substantially as described and shown.

ASSAY-BALANCE.—No. 841,477; Robert G. Ainsworth, Denver, Colorado.



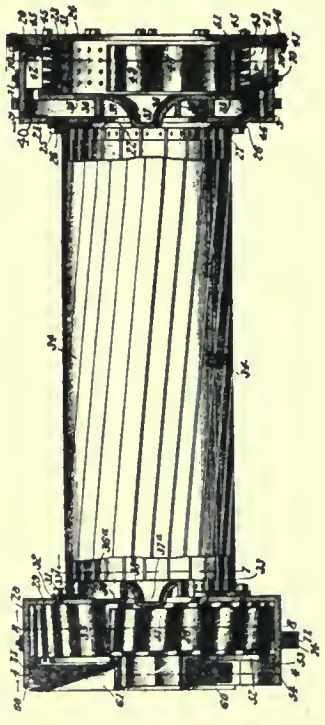
In a balance of the class described, the combination with a balance-beam, of a hanger connected therewith and provided with a horizontal part adapted to hold weight-riders, a rider-carrying lever mounted in suitable proximity to said horizontal part, and means for manipulating said lever comprising a revoluble rod carrying fingers projecting on opposite sides of one arm of the lever whereby the latter may be moved in opposite directions by the manipulation of the rod.

MINING-MACHINE—No. 841,625; William B. Chapman, Wilburton, Indian Territory.



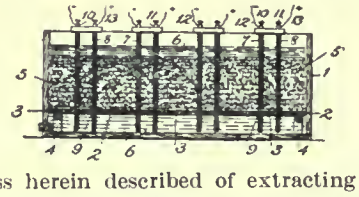
In a mining-machine, the combination, with a vertically-tiltable frame, of a strip secured to the upper face of the frame in spaced parallel relation therewith; an endwise-movable plunger mounted in the space between said strip and frame; a retractile spring connected at opposite ends to said plunger and frame; means adapted to engage the plunger at successive intervals to force the same rearwardly within said space, against the action, of said spring; and means for operating said forcing means.

APPARATUS FOR CRUSHING, CONVEYING, AND COOLING ROCKS, ORES, &c.—No. 840,730; Robert F. Wentz, Siegfried, Pennsylvania.



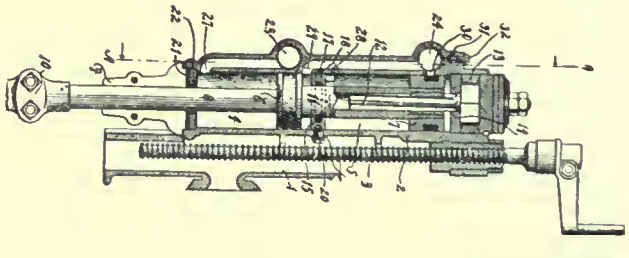
In an apparatus adapted for the crushing of rock, the combination of a rotary cylinder having perforated heads for the feed and discharge of the material, a crushing-cylinder supported within the said revolving cylinder, of a length less than the revolving cylinder and having a perforated periphery, a diaphragm closing the rear end of the chamber formed by the crushing-cylinder, feeding-flanges arranged between the crushing-cylinder and the outer shell of the revolving cylinder, means for directing the crushed material through the opening in the rear head of the revolving cylinder and means for advancing the material through the cylinder.

EXTRACTING METALS FROM SULPHIDE ORES.—No. 840,511; Robert L. Packard, Washington, D. C.



The process herein described of extracting metals from sulphide ores, which consists in converting the sulphides into sulphate by subjecting a body of unroasted pulverized sulphide ore, freely distributed throughout a suitable acidified solution, to the action of chlorin saturating said solution and recovering the metals from said solution.

ROCK-DRILL.—No. 841,139; Arthur H. Gibson, Easton, Pa., assignor to the Ingersoll-Sergeant Drill Company, New York, N. Y., a Corporation of West Virginia.

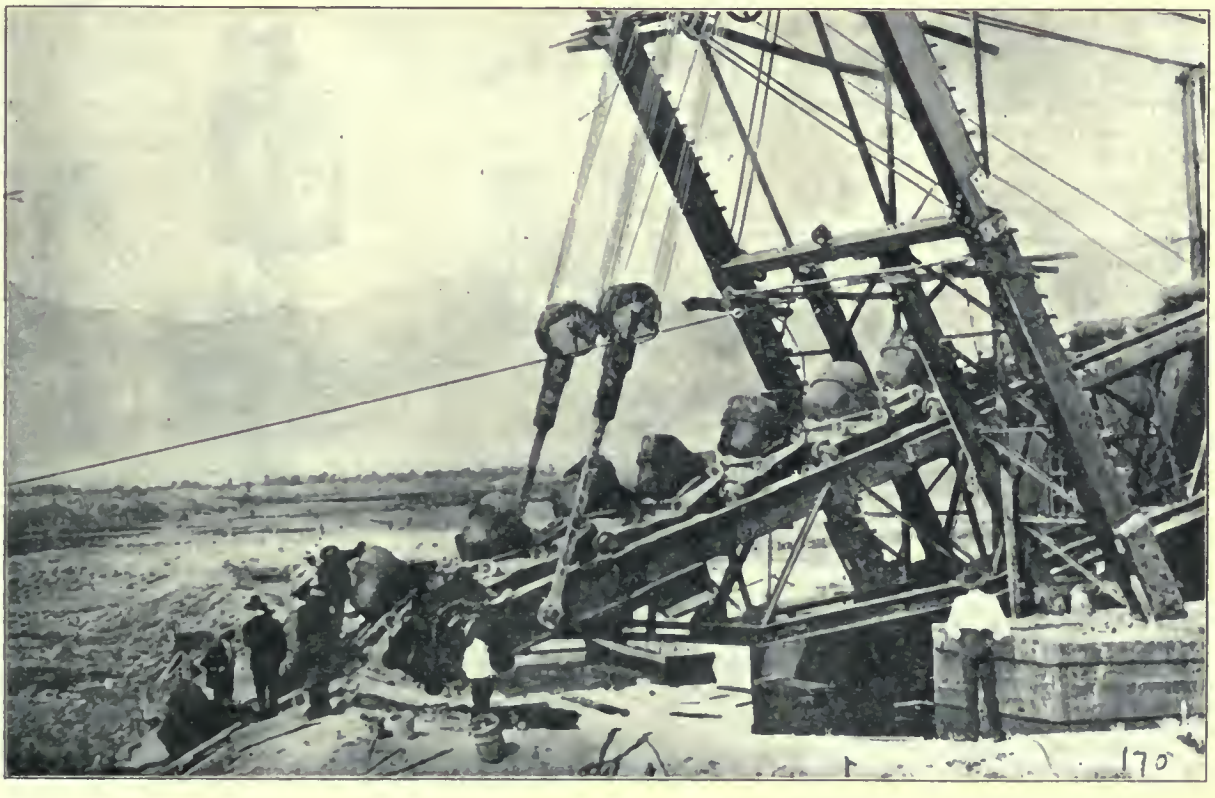


A percussive tool-cylinder, a division-ring dividing the cylinder into front and rear chambers, a piston having front and rear piston-heads, two air-pressor tubes, valveless passages leading from the one air-pressor tube to the front ends of the front and rear chambers and valveless passages leading from the other air-pressor tube to the rear ends of the said chambers whereby the tool-piston may be operated by reciprocating columns of air.

Electricity in Gold Dredging.

The Conrey Placer Mining Co., at Ruby, Montana, has in commission three gold dredges, operating at the mouth of Alder gulch. This locality is celebrated for the large amount of gold produced forty years ago.

Two of the Conrey dredges are operated by steam, one having first started in 1899, the other in 1902. Since then the art of dredging in compact auriferous gravels has advanced so much, and the practice so thoroughly established on safe mechanical lines, that much thought has been given to the perfecting and cheapening of the operating methods. In California it is the general practice to use electric power, but this has been slow of adoption on the Conrey property, owing, first, to the belief that the character of the ground presented difficulties that could be met more readily with the steam power; and, second, to the need of artificial heat, both in water and air, for operation in the winter months. It was decided, however, to equip the next dredge with electric machinery, using a supplemental steam heating for the colder months.



The Conrey Dredge.

Operated by Electricity.

This third dredge is of the single lift, sluice-box type. It was built entirely from designs made by the owners. The hull is 130 ft. long by 48 ft. wide, giving it probably as much if not more area than any other dredge of its kind ever built. It is 8 ft. deep and thoroughly trussed for all the known strains. The ladder-way, or well, in the centre of the forward part, and in which the bucket-chain and ladder work up and down, is 64 ft. 9 in. by 7 ft. 3 in. The ladder is 100 ft. from centre to centre of tumblers. It is of bridge-work construction, built up of angles, a lattice-truss, and a plate-bottom connecting the lower ends of the side flanges. This bottom or cross-plate serves the double purpose of strengthening the structure and providing a trough for some of the slop and spill of the buckets to return to the point of digging under the water.

The bucket-chain is of the open-connected type at present, with 41 buckets and 41 space-links. The bucket complete, with manganese lip and sheet-steel hood, weighs 2,600 lb. The space-link weighs about 1,400 lb. They are all fitted in the back eyes with manganese circular bushings, and connected together with high-carbon steel pins of 5⅝-in. diameter. The upper tumbler is six-sided, fitted with manganese wear-plates and bearing on a 16-in. nickel-steel shaft, the centre line being 31 ft. above the lower deck. On this shaft is suspended the ladder, so that its inclination is constantly the same as that of the chain. On the ladder are 12 steel rollers, 12½ in. diam. The lower tumbler is also six-sided, with face plates and flanges of manganese. It is keyed to a nickel-steel shaft, 13¾ in. diam., the ends of which run in a capped bearing continually filled with oil or grease.

The material excavated is elevated over the upper tumbler, dropped into a steel dump-sheet, where it enters a revolving grizzly, or screen. This is made of ½-in. boiler plate and is 18 ft. 3¾ in. long by 61 in. inside diam., lined throughout with manganese wear-plates. There are numerous openings 4¾ by 6 in. and 6 by 7 in. through which the smaller rocks and finer dirt pass to the sluice-box underneath. The grizzly is set flat, but fitted with spiral angles to drive the large sizes to the discharging end, where they are dropped onto inclined chutes that convey them to either side of the dredge. It is also banded near each end by a heavy locomotive tire, each resting on, and between, two manganese car-wheels. The shaft on one side also carries a gear, which meshes into the train that is finally moved by a 10-h.p. type F Westinghouse induction motor.

The sluice on the upper deck is 28 ft. 10 in. long by 62 in. wide, lined with Hungarian riffles, made up of angles and spring-steel liners. The long sluice on a separate pontoon (40 by 50 ft.) is 135 ft. long and 66 in. wide, also lined with similar riffles. Near the lower end is a set of closely spaced bars, with an opening in the bottom of the sluice itself, permitting a portion of the finer material to be carried into an undercurrent or auxiliary sluice, 54 ft. 6 in. long and 13 in. wide, and lined with wood riffles of the same type. The main long sluice is supported by an angle-iron structural trussing, the whole attached to the boat by a steel adjustable tongue, the connection of the sluice itself being circular, with a pure gum packing fitted between specially designed cast rings to prevent leak or spill. The flume is swung side to side in the pond by means of ¾-in. cables, attached on the pontoon to a manually operated double-drum winch, and to suitable anchorage on shore.

In the well-way also is provided a set of bars, through which the drippings and sippings from the bucket-chains pass to another sluice-box at the forward part of the dredge, provided with necessary riffles. The dredge is swung side to side in the pond by means of ¾-in cables, attached to one

end to the forward part of the deck and leading out to a shore sheave, whence they return to the dredge and connect to a reversible friction type winch propelled by a 10-h.p. type F induction motor of Westinghouse make.

The dredge is held to its work by the mooring line system. This consists of a heavy framing at the rear, on which sets the steel mooring head, revolving on a double ball-bearing and equipped with four sheaves for the lines. These lines are anchored at the corners of a square, about 600 ft. apart. The two forward lines are 1⅜ in. diam., one end being fastened to the mooring head itself, thence running out to a sheave near the anchorage and returning to pass through the mooring head sheave to a large four-drum winch on the lower deck. The winch is equipped with the necessary brakes, friction clutches, etc., weighs about 45 tons in all and is operated by a 30-h.p. type F Westinghouse motor. The two stern lines are one inch diameter and are fastened on one end to the log anchorage, thence running through the mooring head to the winch. When the boat is to be moved ahead after a cut has been taken out, the stern lines are slacked off and the head lines pulled in. The latter also serve to hold the buckets to their work, and the system gives an elasticity for hard digging that is not allowed by the spud method.

The power for the digging is transmitted through a specially built 150-h.p. type F Westinghouse induction motor, capable of 100% overload and a stall of three minutes. It is set on a structural strut connecting the mooring head with the bearings of the upper tumbler; it is pinioned to a specially designed Miller slipping friction, the 7-in. shaft of which is geared to a 10½-in. shaft, carrying a pinion which meshes into the 13-ft. main driving gear on the tumbler shaft. This large gear is of the split hub and run type and weighs 11 tons. There is also provided an auxiliary brake on the friction shaft.

The ladder is suspended by means of two 1⅛-in. lines, working through a double tackle and connected to a Marion hoist, propelled by a 75-h.p. type F Westinghouse induction motor, equipped with a magnetic brake.

To wash the gravel there are one 10-in. Worthington horizontal volute pump, coupled to a 50-h.p. General Electric motor; one 12-in. Morris centrifugal pump, coupled to a 50-h.p. type C Westinghouse motor; one 14-in. Worthington horizontal volute pump, coupled to a 75-h.p. General Electric motor. The total capacity is about 12,500 gal. per minute.

The dredge has a capacity of about 100,000 yards per month, if not more, and operated continually on the 3-shift basis. It commenced digging on September 12, 1906. The gold is fine, flaky, and floury, and is caught by the use of quicksilver freely sprinkled in the sluices.

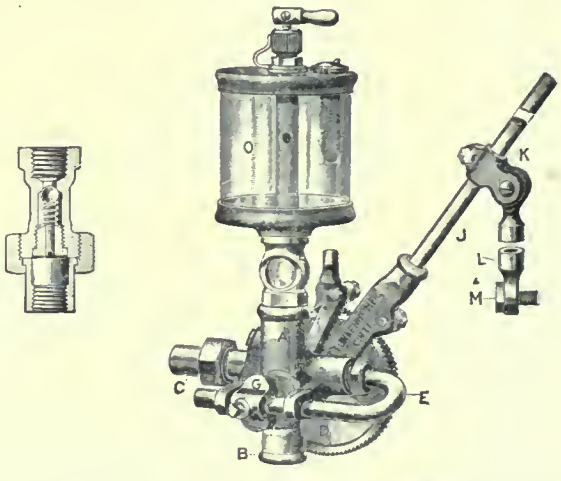
Commercial Paragraphs.

THE HEWITT MACHINERY CO., of 503 Monadnock Bdg., San Francisco, representative for the Atlas Co., state that the Atlas Engine Works of Indianapolis has been awarded a $40,000 contract for the Charleston Navy Yards against the competition of ten other boiler manufacturers.

DENNISTON'S SAN FRANCISCO PLATING WORKS, the old established and successful manufacturers of amalgamating plates, have been in business in San Francisco for 40 years. Their silver-plated copper plates are extensively used in the Rocky Mountain mining region, the Pacific Coast, in Alaska, Mexico, South America, and Australia, to the entire satisfaction of millmen. The demand for these plates is constantly increasing. Only the best Lake Superior copper and refined silver are used, with perfect adherence of silver to the copper, and full weight of silver and copper as per contract. Old plates can be re-plated and made fully equal to new. They are annealed, straightened, and buffed, then silver-plated. Any gold or silver on them is saved. Old plates also are purchased; or gold, silver, and copper are separated at a low cost. The San Francisco establishment was destroyed by fire, during the late disaster, but now larger works have been erected at 1349-1351 Mission St., between 9th and 10th St., which are in full operation, and contain the best and most modern improvements in the business.

An Improved Mechanical Oil Pump.

The Lunkenheimer Company, of Cincinnati, Ohio, are the manufacturers of the pump illustrated herewith, which they have given the trade name of 'Marvel.' As will be seen, the driving mechanism is of the ratchet type, operated by the clutches that work co-operatively by the motion of the rod, which can be attached to the eccentric rod, or other moving parts of the engine by the couplings shown. The motion obtained is transmitted to the piston by the crank-pin mechanism seen on the rear view of the illustration. The ratchet wheel is provided with a handle whereby it can be rotated by hand in case it is desirable to force a quantity of oil at any time, as for example, in starting the engine. The coupling on the rod may be moved up or down, thus lengthening or shortening the stroke of the pump, and regulating the amount of oil fed by the pump, independent of the feed from the oil-cup. Joints of the cup are tight, the sight feed glass being packed so as to prevent access of air that would have a tendeney to cause the cup to feed after the engine had ceased running. This feature and use of



check valves in the pump prevent wastage of oil supply. The feeding of oil is automatic: that is, starting and stopping with the engine. The outlet is connected to the steam pipe or engine valve-chest, and a spring-check valve, supplied with the pump, should be placed in this connection as near as possible to the point of entry into the steam-pipe or chest. The bottom of the pump body is tapped with ⅜-in. bolt-thread to receive a stand so that it can be placed wherever desired. All parts are made to jigs and templets and are, therefore, easily renewed and interchangeable.

The ratchet wheel, pawls, shaft, and yoke are made of tool-steel, tempered and hardened. All other metal parts about the pump are made of the very best bronze composition. Each pump is carefully tested before shipment, and satisfaction is guaranteed. It is listed with and without oil-cup, but it is usually supplied with a Lunkenheimer No. 6, one pint capacity, 'Sentinel,' snap lever, sight-feed cup, and so sent unless otherwise specified. The filling hole is of large area, so as to fill easily, the cup is also fitted with a strainer and hinge cap which cannot be lost. This pump is also made with double-feed and for traction engines, or where a heavy oil is to be fed, the pump is supplied with a compression oil-cup, the oil being forced to the pump by means of a spring actuated plunger in the cup. Where pressure systems have been installed the pump is equipped with a Lunkenheimer 'Reserve' pressure oil-cup, a combination giving perfect satisfaction whenever used.

Publications Received.

ILLINOIS GEOLOGICAL SURVEY.—Bulletin No. 3. This deals with the composition and character of Illinois coals, their distribution over the State, and tests made on them.

ROBINS CONVEYING BELT CO., of New York, issues Bulletin No. 16, describing conveying machinery as applied to the handling of ore. The pamphlet is handsomely illustrated and full of interesting matter, to a degree unusual in trade catalogues. Most of this publication is devoted to illustrated descriptions of important conveyor plants installed by the Robins Co. in large mines, and concentrators.

Editorial.

THE DAILY PRESS has published an absurd story, emanating from New York, that large quantities of copper lie concealed in storage and that the scarcity of the metal is artificial. A man named Norton is stated to have made some startling disclosures to this effect to the President and Attorney-General. It is a cock and bull story of the worst type, but, while it was widely and prominently repeated by irresponsible newspapers, it was not denied or corrected by them when the yarn had been thoroughly punctured. Yet we doubt not that it is being passed on from man to man among the mining camps, as proof positive of a copper trust.

THE ARTICLE on 'Cornish Tin Mining,' by Mr. H. E. West, will be found interesting, for the revival of activity in that historic region is one of the picturesque incidents in modern mining. Of course, the high price of tin is the chief stimulant, but the confident belief that new methods and larger ideas can reduce the cost of operations is also a decisive factor in causing the introduction of fresh capital. The letters of our London correspondent, himself an experienced miner, have made this clear. Among other features of the movement, we note again the fact that while Cornishmen have taught so much of the moden world how to mine, they have allowed their own place of origin to remain a type of unprogressiveness. This is not so contradictory as it seems, for the Cousin Jack is at his best in finding and breaking ore, not in the treatment of it or in the choice of his surface equipment. If the experience of other regions is now to be applied to Cornwall, it is only a fair return for all the mining knowledge that the Cornishman has given to the rest of the world.

AN effort is being made to secure a Geological Survey for Colorado. The movement ought to have the support of good citizens. Such a survey, if properly organized and sustained, would be of great service to that magnificent mineral region, for in no State has the practical application of geology been so valuable commercially as in Colorado. The Leadville monograph by Emmons stands to this day as the type of the most useful kind of geological work. Structural geology plays a large part in the distribution of ore and in order to obtain the data bearing upon the relation that exists between the ore and its encasing rock, it is necessary to have the aid of thorough scientific investigation. The finding of ore is as much more important than the extraction of it, as it is more difficult. And this applies particularly to Colorado, the character of whose deposits is so diversified. There was a time, twenty years ago, when the U. S. Geological Survey had an office at Denver in connection with the

work done on the Denver basin, Leadville, Silver Cliff, and other localities that have become the subjects of valuable treatises. It is a fact that this office, through the men that occupied it, had a most stimulating effect on economic geology in the State and contributed many ideas that were applied with success in the exploratory work of mining. A similar influence would be exerted by a well-organized State survey and if the office could be kept away from the slimy hands of politics, it would redound to the industrial development of a mineral empire—for such assuredly is Colorado.

The Metal Markets.

The outlook for the industrial metals is excellent and high prices are likely to be maintained. The present price for copper is most satisfactory to producers, but the irregular supply of the metal makes business difficult to the dealers. Metal merchants are besieged by customers who want copper for near-by delivery, making demands that it is impossible to satisfy. Recently conditions have been more normal, and if consumers use good judgment and do not rush into the market, the probability is that the scarcity of copper, which at present is greatly accentuated by the fact that production everywhere is falling off on account of the shortage of fuel, will not be so pronounced as the spring approaches. Generally, during the summer months there is a falling off in the demand and this may help to make both ends meet again, which is desirable. The large demand for copper is due mainly to the requirements for electric appliances, and it is not likely that there will be any material decrease in the requirement from this source. Naturally, as time goes on, the high prices will be felt in a great many directions, and we already hear that for copper sheets, certain kinds of brass, etc., consumers refuse to pay present prices, but this is all out-weighed by the demand for wire. It may be said that nearly all the railroads are seriously considering the question of electrifying their equipment, especially on short distances, where travel is extraordinarily heavy, as, for example, to the outskirts of large towns. The experience, short as it has been, on the elevated lines of New York, and on the New York Central, will prove that a tremendous saving in operating expenses can be effected by electric roads, in spite of the high cost of construction. All this insures high prices for copper for probably a long time to come. On the other hand, the increase in production, which one would naturally expect during a period such as the present, will not come about so quickly. There is a great scarcity of labor, and what makes it worse, all the smelters are suffering from the non-arrival of fuel. Phelps, Dodge & Co., the Greene Copper Co., the Old Dominion, and other large producers, have to shut down every few days. The same is the case with the Granby smelter, at Grand Forks, and the British Columbia Copper Co., and now even Butte is suffering.

In spite of the heavy output, there is not sufficient lead produced in the United States for present consumption, and foreign lead constantly finds its way over here, notwithstanding the protective duty of 2⅛ cents per pound. It may be assumed that with the present high prices, the production of ore is as large as it can be expected, and if supplies are not large enough now, what will they be if lead should decline one cent or 1½ cents. This contingency therefore is rather remote.

When the price of spelter reached 5½ to 5¾ cents per pound some time ago, there came complaints from all the galvanizers that the demand would fall off considerably. Meanwhile, production has greatly increased; the price has gone up to 6½ cents at St. Louis, and there is actually a scarcity of near-by spelter. The brass mills have never been known to require as much of this metal as they have during the last six months, and the largest galvanizers are in the market practically every week to buy whatever is offered. It is obvious, therefore, that prices are apt to remain stiff.

How Mining is Discredited.

A trustworthy correspondent writes to say that our remarks on gambling in the shares of mines at Cobalt were "quite mild," in view of the facts. And it may be added that he writes not as a pessimist, but as a mining engineer who has strong faith in the prosperous future of the district. He says: "The Green Meehan mine is capitalized at 2½ million $1 shares. They are selling at $1.40, or a valuation of $3,500,000. Now, as a matter of fact, the mine consists of two open-cuts showing three to six inches of rich ore, but there is practically no ore blocked out, no shaft, or underground work of any sort. Forty-acre lots adjoining the Green Meehan are selling for over $100,000 apiece, with actually not a pound of ore. The Silver Queen mine, with a shaft not 200 feet deep, stands at a valuation of 3½ million dollars. The Silver Leaf, selling at a valuation of $1,000,000, has not a pound of ore in sight. And so on. It is absurd; the bottom will drop out, and before long. A claim with an inch vein of calcite will sell here for from $30,000 to $100,000, according to location." Unbiased statements such as these show the length to which irresponsible promotion can go. It is called 'mining,' but it is no more legitimate industry than the shady practices of the turf are part of the breeding and racing of horses. Speaking of such matters, we desire to refer to a letter on Greenwater that we recently published, much to the annoyance of people who are known as 'boosters.' Two contemporaries undertook to lecture us on the proprieties of journalism, and to them we venture to suggest that they teach their grandmother the pneumatic extraction of the albuminous contents of an egg. Life is too short for a reply to periodicals that are the organs of the unscrupulous kind of finance that is hurting real mining. Greenwater may furnish one or two profitable mines, just as Cobalt can boast several splendid bonanzas, but that does not get away with the fact that both are the scene of a great deal of bunkum and chicanery, holes in the ground being sold as rich mines and hungry prospects as proved properties. The honest enterprises will take care of themselves; we are simply doing a little to create a healthy public opinion, and to prevent the prostitution of a beneficent industry.

By the Way.

In a recent address before the People's Forum, at New Rochelle, Mr. Jacob G. Shurman, president of Cornell University, discussed 'Individualism *vs.* Socialism.' He said:

In recent times in all progressive countries the functions of government have been considerably enlarged. In the United States, for example, the view of government that has hitherto prevailed is that of an institution for the protection of life and property. It rested on the very wise theory that the less men were governed the better. But the growing complexity of modern life and the multiplication of material commodities and the varying conditions under which they are produced and exchanged have compelled modern legislatures to enact laws on subjects not only inconceivable to their fathers, but transcending the limitations set by them for the scope of governmental activity. This necessity has produced a change in our attitude toward the State. We have come to think of it, perhaps in an exaggerated and dangerous degree, not merely as an institution for the protection of its citizens in their rights, but as an association for the positive promotion of the common interests of all its members.

Laws for the protection of working people, and for the improvement of their condition, have rapidly increased, both in the United States and in Europe and Australasia. The lead in this so-called 'State socialism' was taken by Germany, which adopted measures for the insurance of workmen against accident, sickness, and old age. New Zealand, under the leadership of the late Richard Seddon, went still further in the same direction, and established in addition a system of compulsory arbitration in labor disputes. In this country and in England factory legislation may be mentioned as an illustration of the same tendency. And, in a different field, the Federal Railway Rate bill, Pure Food bill, and Meat Inspection bill of last year, with their recognition of the need of Government supervision of certain kinds of private property, were by many people regarded as another example of State socialism.

For my own part I will add that the presumption is always against any extension of the functions of government, as government is already overburdened and the men who conduct it are not equal to the growing task, being neither demi-gods nor heroes, but mere human beings, little, if any, above the average of their fellows either in ability or character. No fallacy is more pernicious than the complacent assumptions that a problem is solved when the task of solving it is put on the President or Governor, Congressman, or Assemblyman, or some lower official of their selection or appointment. The State is not a wise, benevolent, and all-powerful earthly Providence. Concretely realized the State for us is President Roosevelt, Senator Platt, Gov. Hughes, Mr. Murphy, and a number of other political leaders and public officials of similar or inferior standing and influence.

It is a widespread belief that certain political, social, and economical evils can be obviated or mitigated by public ownership of industries which in their nature are monopolistic. Under this conviction cities have become owners of waterworks, gas, and electric light plants, tramways, and street cars, and States have purchased or constructed railway, telegraph, and telephone systems, and even undertaken the business of banking and insurance. * * * Now, I do not understand that any appreciable advance toward the millenium has anywhere resulted from the municipal or State ownership of public utilities, though I am far from opposing that system of ownership. On the contrary, I know that if in Germany you want a good train on a Government railway you must take one run by a private company which has its arrangements with the Government. I know that in London, where municipal ownership had been carried almost to an extreme, mismanagement, especially in connection with the street cars, the river boats, and the electric service, entailed such enormous municipal debts that the rates or municipal taxes were greatly increased, and the supporters of the municipal ownership policy were overwhelmingly defeated at the elections only a few months ago. I know that in Russia, which is the most perfect exemplar of State and municipal ownership, you find as a consequence a highly centralized government and a corrupt beaureaucracy which is not only morally reprehensible, but which yields in practice the worst service in the civilized world.

I do not want to see a Government despotism in the United States. I dread the bureaucracy which Government ownership of American railroads would make inevitable. I can see nothing but folly in a policy which would call for Government loans of billions of dollars to purchase the railroads and which would entail the loss of billions of dollars in mismanagement and corruption under political control after the roads had been taken over by the Federal and State Governments. No Government in the world is qualified to go into the railway business, and least of all the Government of the United States, which draws its life from party politics and in which all administrations are necessarily short lived.

We have witnessed in the last two or three decades an enormous increase of wealth in the United States. All classes of the community have profited by this enrichment. But the feature of this economic phenomenon which stands out most conspicuously, which attracts all eyes, which throws everything else in the shade, is the large and, in some cases, colossal fortunes accumulated by certain individuals. This feature so completely obliterates all others that many thoughtless and ignorant people assume that impoverishment of the many has resulted from enrichment of the few. Others, again, suppose that the fortunate few have robbed them of opportunities of becoming wealthy by monopolizing fortunes of which they were entitled to a share. All this vague thought and sentiment rests on the tacit assumption that wealth, like dirt, is lying round and needs only to be picked up, and that one man has as good a right to pick it up as another.

The fact is that wealth is a creation. The colossal fortunes of the millionaires and billionaires, excepting, of course, those that have been dishonestly acquired, are positive contributions to the sum total of human wealth. These fortunes have been created from possibilities of nature and human society divined by the genius and organizing ability of great captains of industry. The rest of us would not be the richer, but poorer, had these men of economic genius not created their vast fortunes. And I have no doubt that in the material world and in the needs of human nature there are still infinite possibilities of wealth open to any of us who have the genius and skill to utilize them.

Does anyone pretend that the United States would today be a better country to live in if we were all poor, if there were no millionaires and billionaires, or if the sons of millionaires and billionaires squandered the wealth which their fathers had accumulated? The very question reveals the folly of the underlying assumption. What we want is not a diminution in the wealth of any individuals or a reduction in the number of wealthy men, but an increase. And every increase is so far from being a detraction from the prosperity of others that in its results it is a boon to them and to the community.

Mining Summary.

ALASKA.

(Special Correspondence).—The Alaska Copper Co., at Coppermount, has a 250-ton matte smelter at its property, which operated four months last year. Its present idleness is due to an insufficient coke supply. At the mine a long adit is being driven to open the sulphide orebodies. This will cut the vein 1,100 ft. below the apex of the mountain, and 1,200 ft. above sea-level. The property, which is directed by an executive committee, has an office in Seattle. —— C. L. Parker, and associates, of Seattle, are mining on Cleveland peninsula, on Helm bay, in the Ketchikan district. Their property is well opened by adits, and there is a winze on the lode that yields gold ore. The surface improvements comprise a five-stamp mill, now in operation; a gravity tramway from mill to mine, and a railroad from the water-front to the mill. The ore is, in part, free-milling, the balance being concentrating.

Portland, Feb. 1.

Recent reports from Candle City state that there are over 100 people living there this winter, and that there are fully 400 miners on the creeks in that district, and 45 more on the Kugruk, which is 25 miles distant. Guinan, McDonald, and McIntosh are carrying on the most important operations. One dollar to the pan at bedrock is not uncommon on their property, and the small buckets used for hoisting average about $5. Coal for the mines is brought from Kugruk creek. Two steam-hoists and 15 men are working for this outfit on Candle creek.—— A rich strike is reported on Montana creek, a tributary to the Kugruk. A 24-h.p. boiler has been installed there. A new $4,000 hospital has been built in Candle, by subscriptions from the miners.

Extensive prospecting is being done on Solomon river. A number of outfits are at work with steam-boilers, and bedrock has been struck at a depth of only 15 ft. The shallow bedrock makes development easy, and the gravel is easy to handle, being coarse, but without many large boulders. At Nome, the first beach line, which lies about 1,500 ft. back from the sea, is showing up well, and seems to extend from Snake river to Cape Rodney. Strikes have been made averaging 12 and 15 ft. below the surface, running about 10c. per pan. The shallowness of the pay-streak makes it easy to work.—— The vicinity of Bluff is being prospected vigorously, on the third beach. Lapelle is taking out a dump, from ground of the Northern Mining Co. The beach is over a mile back from the sea, and 20 outfits are working, although only a few are down to bedrock.—— Many outfits are working on the third beach from Anvil creek to Penny river. The Wild Goose Co. is the only one that has yet reached bedrock.

All of the mines and mills of the Treadwell system have been closed, owing to lack of fuel. The Treadwell mine and the 240-stamp mill were the last to suspend operations.—— The Treadwell management is putting in oil burners, and in the future the mine will be operated with this fuel. An independent line of tank-steamships will be run by the company.——The Treadwell mines employ about 1,500 men, and the Perseverance about 100 men.

ARIZONA.

GILA COUNTY.

(Special Correspondence).—The Blackhawk and Copper Hill mines of the Arizona Commercial Co., in the Globe district, which have been idle for some time, are being worked, sufficient fuel having been secured.——The reduction works of the Old Dominion M. & S. Co., which have been closed since the first of the year on account of the shortage of fuel, have resumed operations with two furnaces. Coke and fuel are arriving daily and the other furnaces will soon be started. The shaft on the Gem claim of the Globe Consolidated Co. is at the 370-ft. mark and is in diorite. It is expected that the 500-ft. level will be reached within three weeks and from this point lateral development work will begin.——Orders have been placed for machinery for the claims of the Superior & Boston Co. W. E. Carter is foreman, and he will also have charge of development work on the Great Eastern, Black Oxide, and Limestone mines.—— At the Mallory mine, the vein on the 460 level is being explored at three points by drifts. About 40 ft. of driving has been done along the vein. The ore runs from 1 to 5% copper.——The railroad being built by the Arizona Commercial Co. to the Copper Hill and Blackhawk mines is awaiting construction material. About a mile of steel has been laid.

Phœnix, Feb. 3.

GRAHAM COUNTY.

An important deal has just been made in the Clifton-Morenci district. Los Angeles capitalists have purchased or bonded a large area in the centre of the mineral belt, made up of about 160 claims. This deal includes the properties of the Stevens Copper Co., consisting of 48 claims; the Julius Lezynsky group of 34 claims; and the Elliott-Wright group of 27 claims. With the consolidation of all these properties, this new company will have holdings on each side of Chase creek, and extending from the west side of American Mtn., near Eagle river, to the region east of Metcalf, and nearly to the Frisco river.——Owing to the high water in the Frisco river, which interferes with the improvised pumping plant of the Arizona Copper Co., the smelters were forced to close down for a short time. There has been considerable difficulty in getting sufficient water to run the plant of this company, ever since the washing away of the old dam across the Frisco river in December.

MOHAVE COUNTY.

At the property recently purchased by New York capitalists from C. G. Werner, work is progressing rapidly. The mine is situated in Box cañon, 18 miles northeast of Florence. The tunnel when completed will be about 1,200 ft. long, and will cut the Arizona King vein at a depth of about 500 ft. An air-compressor, boiler, and machine drills have been ordered.——A carload of copper glance rich in silver has been shipped from the old Queen mine at Superior. The ore was taken from the 300-ft. level. This district has produced some rich ore, the old Silver King having been famous as a high-grade shipper.——Thirty men are employed by the Picacho Mining Co. The mine has been bailed out, and men are driving on the 200-ft. level. The railroad from the mill to the mine, a distance of five miles, is being put in shape.

SANTA CRUZ COUNTY.

There is a good deal of activity near Patagonia. The Happy Jack Mining Co. has a tunnel in 900 ft. Ore is being shipped regularly.—— The Pride of the West in Washington camp is shipping good ore, and the old Mowry mine is turning out a good amount of lead and silver bullion. The Alta mine, about 12 miles northwest of Patagonia, is sending ore to the El Paso smelter.——The Mansfield company has a shaft down 160 ft.——The Gringor company has a 5-stamp mill running and will add 10 more.——The Presidential property, about one mile southwest of Mansfield, has a good showing of ore, and 12 men are employed. ——The Santa Cruz company is working a force of men on its property, two miles east of Patagonia, and has a shaft down 350 ft.——The Flux mine is producing lead carbonates, as is also the Hardshell property, both owned by R. R. Richardson and now under bond to California parties.—— The Dawson mine, 10 miles northwest of Patagonia, has just struck good ore in the foot-wall. This property has been operated by W. P. Blake, of Tucson, for four years.—— A consignment of ore has been shipped to the El Paso smelter by the National Consolidated Mining Company.

CALIFORNIA.

BUTTE COUNTY.

At a recent meeting of the operators in the Oroville dredging field, the subject of the injunction suit threatened by the Anti-Debris Association was discussed. No objection was made to the muddy water which finds its way into the river by percolation, but the Anti-Debris Association does object to the open ditches from the dredgers and dredging ponds, which run directly into the river. Another point is the fact that there are no restraining walls to prevent the river, at high water, forcing its way into the ponds and tailing piles, and carrying down stream a load of gravel and sand. A stay of proceedings has been granted to the operators, until they can investigate the grievances of the Association.

EL DORADO COUNTY.

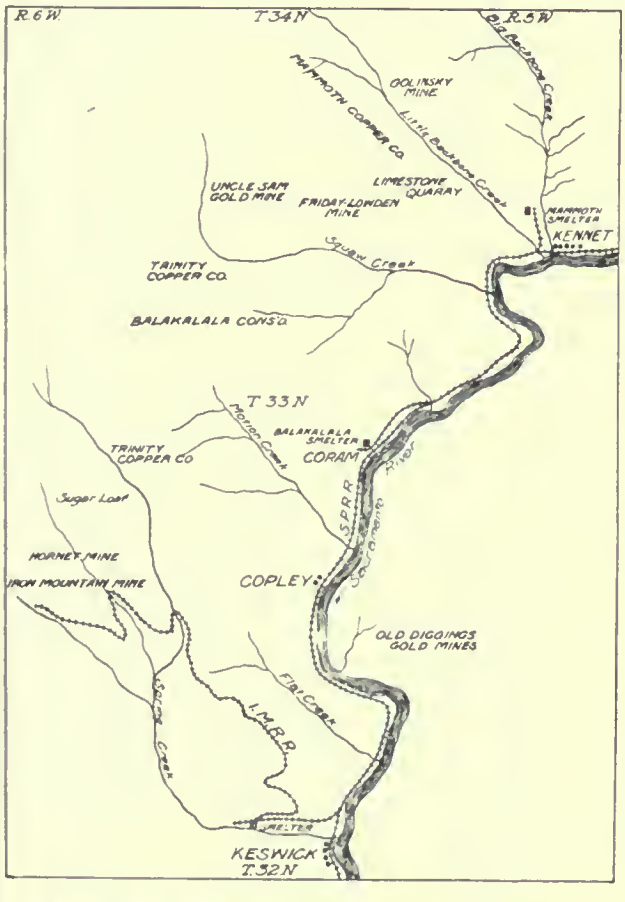
The El Dorado canal is still clogged with snow and ice, none of the mines are able to run, and the machinery at Placerville is only being run for temporary purposes.——All the mining in Consumnes township is stopped by a break in the Plymouth ditch. It will be six weeks before much water can be obtained for mining.

INYO COUNTY.

On Feb. 10, a new agency station, named Sperry, will be opened at the end of the track on the Tonopah & Tidewater railroad, three miles north of Dumont (the present terminus), and 78 miles north of Ludlow, Cal. Thereafter Dumont will be a non-agency station, and freight consigned to that point must be prepaid. All freight and passenger business for Greenwater and points beyond the end of the track should be routed to Sperry, as all freighting lines and stages will arrive at and depart from that point.

NEVADA COUNTY.

The new power-line from Colgate to the Boss mine, near Sweetland, has been completed.——Prospecting is still going on at Iron Mtn., and cross-cutting has been started, to cut the copper lode.——The Colfax mine at Willow valley has developed good ore in the lower tunnel, about 400 ft. from



Map of the Copper Region in Shasta County, California.

the portal. A shipment of high-grade ore will be made soon to the Selby plant.

PLUMAS COUNTY.

The coming of the Western Pacific railroad is expected to open up a rich district in the northern part of this county. The Plumas-Eureka at Johnsonville has a good record as a producer, and the railroad will open up the Greenville mother lode district, ranging from Taylorsville, through Crescent Mills, northward to the head of Wolf creek. To the west is the Seneca district, which will also be reached by the new road. Free-milling gold-quartz has been found there in many places. The Indian Valley region has some good copper lodes, especially in Lights cañon.——The old Gruss mine, at Ward creek, has produced half a million in gold, and a tunnel has been run 1,400 ft. on the lode.——A tunnel has been driven into Cooper hill, and Salt Lake parties are large owners in the district.——The North California Mining Co. has done a great deal of prospecting along the northern and western boundaries of the county, and has built many trails and roads.

SHASTA COUNTY.

Another strike is reported in the Lappin mine, near Deadwood. A two-foot lode was struck in a cross-cut, and is followed by this new strike in the shaft. Sixteen men are employed, but no stoping or milling will be started until the spring.

The Keswick smelter is to be repaired and blown in again. Probably but two of the five furnaces will be overhauled at once, with the idea of keeping one furnace running continuously. Low-grade ore from the Hornet mine will be treated, as well as some from the Iron Mountain, and the resultant matte will be shipped to the Martinez reduction works, which are owned by the Mountain Copper Co. The restoration of the smelter is rather a large undertaking, as much of the machinery was removed to Martinez. Pipes were disconnected, hot-air blasts torn down, six McDougall furnaces were removed, motors shipped away, and wiring taken down. Nevertheless, two of the furnaces are expected to be in shape inside of two months. Lewis T. Wright is the general manager, and F. H. Goodspeed is the superintendent of construction.——It is reported that within a few months a test run will be made in smelting iron by an electric furnace process, in the preliminary plant now being constructed by H. H. Noble on Pit river.

SISKIYOU COUNTY.

(Special Correspondence).—The Blue Ledge copper mine, bonded to Robert S. Towne, of New York, has undergone thorough development within the past year. Five adits, from 200 to 800 ft. in length, have been driven. Besides this, over 7,000 ft. of diamond-drill prospecting has been done. The ore carries 5% copper, $2.50 in gold, and $1.50 in silver per ton, the orebodies occurring in the schist and slate. Mr. Towne has expended $200,000 on the property, and it is anticipated he will take up the bond. The mine is 35 miles from Medford, Ore., and 120 miles from the coast. A railroad may be built to the mine and a smelter erected there.

Medford, Feb. 3.

(Special Correspondence).—The Alta Con. M. & M. Co., operating on Hungry creek, six miles from Coal station, will complete its mill this spring, and treat its ore by amalgamation and cyanidation. O. C. Tiffany of Ashland, Ore., is manager, and Frank Morin, of McLeod is interested. H. Crouch will have charge of the mill.

Ashland, Feb. 6.

TUOLUMNE COUNTY.

(Special Correspondence).—The Horse Shoe Bend Gold Mining Co. has purchased a 40-stamp mill and will erect it on the property, situated on the Stanislaus river, as soon as the weather permits. The company will continue development the coming spring.——The Yorktown mine, situated on the Ida Klein ranch, near Stent, which has been attracting attention as the result of a rich strike, has passed into the control of F. B. Keever, of Boston. A hoist and other machinery will be installed at once, the crew increased and development pushed at a rapid rate. J. F. Bryson is superintendent.——The Pennsylvania shaft of the Soulsby mine has reached 800 ft. and driving on this level was commenced a few days ago. The shaft is 400 ft. deeper than when the Bagdad-Chase company began operations. At the Davidson shaft of the Soulsby a new concrete foundation has been placed under the machinery which operates the jackhead pump.——It is said operations will be resumed at the Kanaka, Fair Oaks, Prudhomme, Del Monte, Mt. Jefferson, and the Cosmopolite. Operations ceased at the latter mine only a few weeks ago, as a result of the severe weather. The Mt. Jefferson will be in activity as soon as electric power is available, which will be about May 15.——Negotiations for the sale of the Black Oak mine, near Soulsbyville, are reported to be in progress.——The Imperial Gold Mining Co. has filed articles of incorporation in this county. The capital stock is 1,000,000 shares of $1 each. The amount subscribed is given as $350,000. The directors, thirteen in number, are all residents of San Luis Obispo county.

Tuolumne, Feb. 3.

COLORADO.

BOULDER COUNTY.

The main shaft of the Pine Grove mine, near Wolfram Junction, is down 180 ft., and is being sunk fast. The shaft is going down on the main vein, which is often six feet wide, and carries some shipping ore along with the second-class. Levels have been opened at 80 and 160 ft. J. Collins is the superintendent.—— The Spencer Mountain Tunnel Co. is working steadily in the east branch of the Mogul tunnel. Six thousand feet of workings are now open, and the adit is designed to drain all the mines of Spencer, and is expected to cut the veins at a depth of 1,000 ft. J. A. Gilfillan is the superintendent.—— The Alton company has completed 650 ft. of the tunnel which is to be driven 3,000 ft. under the Sherwood flats, and work is progressing rapidly. Hand-drilling is done now, but the company expects soon to install a compressor. At a recent meeting H. R. Burns was elected president; W. A. Burke, treasurer; H. F. McClellan, manager, and Jas. Cheney will be the superintendent.——The shaft of the Livingston property, at Sugar Loaf, is down 300 ft., and will be pushed to the 1,000-ft. level. This mine is reputed to have already produced $400,000 in gold.

CLEAR CREEK COUNTY.

(Special Correspondence).—Great activity prevails in the Georgetown district, and a number of concentrating mills are being built. The machinery for the East Griffith mine was put in place this week and there are enough lead and zinc-ore reserves to insure a steady output. The Democrat Mountain Mining Co.'s new 50-ton mill has started, and is doing good work. Ores from the Boston and Beecher lodes, cut in the Moline and Kelly tunnels, are being treated. The Nashatah mill, situated below the portal of the Diamond adit is running, and from 100 to 125 tons of dump material are being concentrated daily. This is said to be one of the most modern plants in Clear Creek county. Work was started last week upon the Homestake group of six claims, situated on Lincoln Mtn. The cross-cut, now in 40 ft., is to be driven with all possible speed. The first lode to be intersected is the Homestake, 50 ft. distant, which from surface produced high-grade gold-silver ores. A new strike is reported from the Ramsdell mine, also situated on Lincoln Mtn. In shooting into the hanging wall a 10-in. streak of ore was uncovered which assays 20 oz. gold and 120 oz. silver per ton. George W. Teagarden is the general manager. The Doric tunnel property which has been idle for the last two months, will again be operated, and stoping on the Magnet and Sequel lodes will be resumed. In both stopes a streak of fair-grade ore is showing, which can be mined at a profit. Riley Bros., leasing on the famous old Stevens in the West Argentine district, have uncovered an 18-in. streak of silver-lead ore. The first shipment of five tons brought returns of 60 oz. silver and 55% lead. Stoping is in progress. John Bowen, leasing on the upper Frostberg on Sherman Mtn. will start shipments within the next 10 days. A drift is in 100 ft. and the ore-shoot has been found. The streak is 18 in. wide and carries silver values of 150 oz. per ton. Steady shipments mark the progress of development on the Smuggler, located on Brown Mtn. The average value of the smelting material is $100 per ton, while the concentrates bring about $50 per ton. A number of leases have been issued on the property and every lessee is working. Work in the Crowfoot adit has been resumed. The bore is now in 4,800 ft. Wm. M. Cooper is the manager. The ore-body in the lode intersected measures from 5 to 12 ft. in width, carrying from 2 to 3 oz. gold per ton. Hundreds of tons are in the ore-bins, but owing to the crowded condition of the custom mills it cannot be handled. A mill of a capacity of 200 tons per day is to be erected at once for the treatment of this material. This property is within the corporate limits of Georgetown. Carl Nelson, leasing on the Gold Dirt, has a body of ore eight feet in width, carrying values of 4.4 oz. gold per ton. Shipments are being made to the Denver smelters. These lessees have a block of ground 350 ft. long by 300 ft. deep. One foot of smelting-ore has been opened on the Denver City property on Coyote Mtn. The discovery was made at a distance of 500 ft. from the portal of the cross-cut, where the Louis J. lode was intersected. The values will probably average $50 per ton, principally in gold. The Philadelphia Gold Mining Co. has been incorporated with a capital stock of $100,000. The company will operate a group of 17 claims on the south slope of Bellevue Mtn. The Little Chief cross-cut is to be continued. Jos. Boyd is manager.——Operations have been resumed on the Prince Albert mine located on Columbian Mtn. Shipments were started to the Georgetown sampler this week, the ore bringing $40 per ton. D. J. Williams of Lawson is the superintendent. A contract was awarded this week for running the two lower adits on the Stemwinder 200 ft. further. The lower level is being driven east from the bottom of the shaft at a depth of 35 ft. It is hoped to again catch the shoot from which ore running 325 oz. per ton was extracted a few weeks ago. Work on the Ramsdell mill was started this week. The contract calls for the completion of the same within 90 days. The capacity is to be 75 tons daily, straight concentration.

Georgetown, Jan. 31.

SUMMIT COUNTY.

(Special Correspondence).—The Colorado Consolidated Electric Co., which last year took over the property of The Gold Pan M. & M. Co., has given an option on all of its holdings to Ben. S. Revett, the dredge operator. The option covers all water rights, ditches, flumes, pipe lines, manufacturing, electric power, and lighting plants and machine shops. It is Mr. Revett's intention to supply his dredge on the Reliance property in French gulch with electric power and to operate dredges on the Blue and Swan rivers by electricity. It is estimated to take 200-h.p. for each dredge. This, with the lighting of the town of Breckenridge and the supply of power to mining plants will use all the power that can be generated.——Robert A. Niles, who has had charge of the Blue Flag Mining Co.'s affairs since its organization, has resigned from his position as superintendent and is succeeded by Charles M. McGrew. Mr. Erisman, the president, visited the property last week. Milling operations will be resumed in the spring.

Work on the Senator mine is being carried on under the supervision of M. M. Howe, and a force of 20 miners are employed. No shipments will be made until the road is opened up in the spring.——The Wonderful London mine, is being developed at depth. A force of 15 men is employed and the main shaft is now down 500 ft.——The Puzzle Gold Dust mine is under new management. W. A. Walker of Mt. Pleasant, Ohio, has been appointed manager, and the superintendent is John B. Nelson. A large body of lead and zinc ore has been struck in the raise above the main tunnel level. This will provide ore for the concentrating mill which is soon to be started.——The Wellington Mines Co. is employing a force of 25 men. Loading chutes have been built, and six teams are hauling ore.——The Maize Co. is doing work on Rock Creek, north of Dillon, on the Boss and other lode-claims of their group. The main tunnel has intersected the old Boss vein at depth, and a body of silver ore has been opened.

Breckenridge, Jan. 23.

IDAHO.

BLAINE COUNTY.

(Special Correspondence).—The Wood River Zinc Co., operating near Hailey, under the management of John Williams, has been for some time shipping six cars of ore per month from its Nayaug mine, which yields 50% lead, 60 oz. silver, and $12 gold. The zinc ores have accumulated to the amount of 30,000 tons. The latter ore carries lead, silver, and gold in addition to the zinc. It will now be milled.

Portland, Feb. 1.

LEMHI COUNTY.

(Special Correspondence).—Definite information has been received that the Oregon Short Line will build a line this year from Armstead on the Utah Northern to the Gilmore district in Lemhi county, a distance of 70 miles. The Gilmore property and the properties of the Junction Mining Co. have been consolidated and a large smelting plant is to be erected. Ore from the Gilmore has heretofore been hauled 70 miles by wagon.

Spokane, Jan. 20.

SHOSHONE COUNTY.

(Special Correspondence).—The Champion Co. has been incorporated for $1,250,000 to develop a group of 12 claims north of Mullan and Snowstorm hill. The officers are: C. H. Reeves, president; F. H. Harper, vice-president; M. R. Keith, secretary; W. S. McCrea, treasurer. The foregoing, with E. J. Harper, Al. Harper, and J. T. Ome, constitute the board of directors. The property has been developed, and a well mineralized vein of good proportions has been exposed. Work will be begun at once under F. H. Harper on a tunnel which will run 1,200 to 1,500 ft. to crosscut the level at depth.—— R. H. Pascoe, superintendent of the Standard mine, is authority for the statement that an important strike has been made on the International. The managers of the property claim they have struck the Hercules lead. The International is east of the Hercules, and is separated from that property by only one other—the Ajax. The principal owners are: H. F. Knight, Wallace; R. H. Pascoe, Mace; W. J. Hall, and Ellis Hale, Wallace.—— A strike of three feet of miling galena-ore has been made in the Arlington mine, six miles east of Burke. The lode carries three inches of shipping ore. Cyrus W. Gossert, of Wallace, is president of the company. Much of the stock is held by Boston people. The same lode was opened 500 ft. higher on the hill, so the recent strike gives the mine an immense stoping ground. The strike was made when the lower tunnel was in 70 ft. The company owns 20 claims.—— Word from Wallace states that a smelter will be built at Mullan by Eastern and Butte capitalists, and the Greenough interests. Frank D. White, superintendent of the Amador smelter, announces that a location has been selected just east of the Snowstorm mill. The smelter company will erect a long aerial tramway to Copper mountain to handle the ore from the producers of that district, and the Hunter mine will send its ore to the Mullan smelter.—— At a meeting of the directors and shareholders of the North Franklin Mining Co. in Spokane, it was decided to increase the par value of the company's shares from $1 to $5 per share. The company is incorporated for $1,000,000, and the treasurer was required to file a bond for $25,000. The property of the company is 800 ft. north of the Morning mine at Mullan, and arrangements have been completed with the Federal Co. by which a supply of air is conducted from the lower tunnel of the Morning mine to the North Franklin property, and in this way the installation of a compressor is not necessary. Three shifts of men have been employed for some time.—— Contracts have been awarded to S. W. Merrill to drive a 500-ft. tunnel on the property of the Nonpariel Co., which lies south of Mullan, adjoining the Carney property. The surface buildings have been completed and work will be pushed. The contract stipulates a minimum of 50 ft. of work per month. The tunnel has been started on the vein, and when continued for 3,000 ft. a depth of 1,420 ft. will be had on the vein. The iron on the surface carries from 8 to 10 oz. silver, and from 1 to 1½% copper.——The Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 112 of $180,000 Jan. 4. This makes the total amount of dividends paid to date $8,046,000.—— The option on the control of the stock of the Rex, held by F. J. Finucane, supposedly in the interests of the Federal Co., has been surrendered.—— An assessment of five mills per share has been levied on the stock of the Oom Paul Mining Co. This assessment will bring into the treasury nearly $5,000, which will be enough to carry the workings into the orebodies. A compressor has been installed.—— The Yellowstone group of three claims adjoining the Copper King mine, near Mullan, has been bonded to E. J. Hunter, of Spokane, who will incorporate a company to handle the property.—— Herman Hueman, of Wardner, and Richard Emmons, of Galena, Kans., will install a tailing plant at Wallace. It will treat 15 tons of tailing daily, hoisting from the river bed by two 14-in. buckets.—— A strike of rich galena-ore was made in the upper workings of the Daisy mine, near Mullan, a few days ago. The orebody varies from 18 in. to two feet. The mine was acquired by the Greenough interests two months ago.—— J. C. Jensen, superintendent of development work now being done on the Lewiston group in Moon gulch, reports a strike of importance. In the lower tunnel, which is now in 95 ft., a fine body of galena-ore has been encountered.—— The Assaska Mining Co., a new corporation, has purchased five claims in the Cœur d'Alene district from J. H. Marks. The property was secured for $75,000, the seller taking stock in the company for a large part of the purchase price. The new company is composed of Spokane men, with J. H. Marks, president; W. Steffer, vice-president; S. J. Crane, secretary, and B. N. Hodson, manager. The company's property has been developed by a 200-ft. tunnel and a number of open cuts and shafts.—— Copper ore has been found in the Log Cabin mine in the Black Lead district in the Bitter Root Mtn. H. Gerber, one of the owners, says the Log Cabin ore is similar to that of the famous Murray producers. The ore carries some native copper, and values in gold and silver.—— At a meeting of the Transcontinental Mining Co. the following board of directors was elected: President, W. W. Woods; vice-president, Frank Hutchins; secretary-treasurer, George E. Marlowe; directors, W. W. Bixby, and Thomas C. Marshall, of Wallace. George E. Marlowe was appointed manager. The company owns nine claims in the Hunter district, 400 ft. north of the Reindeer. The property is traversed by a strong vein, and assay returns of ore taken from the grass roots give 4% copper, and 3½ oz. silver.—— The Crescent mine, a few miles east of Pierce City, is to be worked again, and active development work will begin early next month. R. E. Willoughby has purchased the mine from the Bone Mining Co., to which corporation the property has belonged for years. The price paid is $20,000. The property is well developed by tunnels, shafts, and pits, and is equipped with a five-stamp mill, a sawmill, hoists, and other machinery.

Spokane, Jan. 30.

NEVADA.

ESMERALDA COUNTY.

The shaft on the Frances lease of the Polverde claim of the Jumbo extension is being sunk. The 50-h.p. hoist from the Frances-Mohawk lease has been installed, and an eight-drill compressor will be used. A station-pump, electrically driven, will be placed on the 300-ft. level, to take care of the recently encountered water.——The report that the Consolidated company had asked the District Court to stop work on the Jumbo Extension until the apex-rights to the orebody had been determined is denied. Apex litigation between the Mohawk and Combination mines was avoided by the purchase of the latter by the merger company.

LINCOLN COUNTY.

(Special Correspondence).—The Vincent mining district (unorganized), situated 25 miles southeast of Los Vegas, has produced ore rich in gold. The Catlin property has three tons of ore sacked ready for shipment and is sacking more. This property is reported sold at $60,000. A Hartford, Conn., syndicate is working in this district, and reports having encountered some rich ore. Thos. Hays, of Salt Lake, also reports a rich strike, and the district looks lively.——Gravel Gulch is shipping rich copper ore from Moapa.——The Vegas Copper Co., 30 miles southwest of Los Vegas, will sink a 100-ft. shaft. A small shipment of 10% copper ore was made from this property.——The Lucky Strike, 25 miles northwest of here, made a small shipment which returned 70% lead.——The Potosi, 25 miles southwest, continues to ship 35 to 40 tons per day of lead and zinc ore.——The Vegas Artesian Water Syndicate is loading machinery at Los Angeles, and will shortly commence its first bore, two miles from here.

Los Vegas, Jan. 29.

(Special Correspondence).—The Searchlight Consolidated Co. is grading for the foundations of its new plant, and machinery is on its way. Owing to the scarcity of lumber in the district, Mr. Egge, the superintendent of the property, has ordered the material for the head-frame from Los Angeles, and the first carload will be received this week. In addition to the hoisting plant, the company has ordered a full equipment for a machine shop, and will be prepared to do lathe work, and will have the best and most complete mine equipment in the district. Considerable difficulty has been experienced in sinking the shaft, as the ground was heavy and had to be timbered closely.—— John Hug-

gins, who has charge of the Quaker City group, is now timbering the shaft on the property, which is down 75 ft., and it is the intention of the company to sink to 300 ft., and then cross-cut to the west, to cut the vein of the June Bug, from which Paul Barlock has been extracting some rich ore.——At Camp Dupont, Colo., D. H. Jackson has installed a whim on the Golden Terra and put on three shifts of men sinking the shaft, which is now 80 ft. deep. George Dupont has cut the vein in the breast of the 400-ft. cross-cut that he has been driving for the past few months. The ore in the vein at this point shows copper, gold, and silver, and the width of the vein is not yet determined.—— On the Copper & Iron claim, Scotty Price has struck ore at a depth of 28 ft., the bottom of the shaft showing values in gold and copper.—— A report is current that the Empire mine at Newberry mountain has changed ownership on a basis of 75c. per share for outstanding stock.——The Searchlight Co. has installed a new Dean duplex station-pump at the third level, of a capacity of 200 gal. per minute, and is sinking the shaft. The company has some ore on the third level, and now they are prepared to control the water; the lower levels will be opened as rapidly as the sinking will permit.

Searchlight, Jan. 26.

NYE COUNTY.

(Special Correspondence).—Activity in mining has been hampered during the past month by bad weather. The snowfall has been much heavier than usual, and travel by automobiles between Manhattan and Tonopah has been entirely suspended and freight traffic greatly retarded.—— Developments in the Mustang property are of interest. Work on this property was recently started by J. C. Humphrey, the present superintendent. The cross-cut on the 210-ft. level encountered a vein of quartz, showing gold and sulphides.——On the Chipmunk property, adjoining the Mustang, driving is progressing on a vein encountered by a cross-cut on the 100-ft. level. A hoist will arrive soon, and the shaft will be sunk.——Developments near Central continue. Among the active operators is the Monday Extension Co., which is driving on the 40-ft. level. Report has it that lessees are to work some surface-ores by rockers. The Ivanhoe property, including the Hooligan claims, is being developed on the 100-ft. level, and a hoist is soon to be erected.——The Consolidated is doing work on the Silver Pick claim. Timber for shaft-work is difficult to obtain, owing to freight congestion. Recent development in the lower workings shows no abnormal increase in water.—— Prospecting with drills similar to those used in the California oil-fields is to be tried on the Wolftone Extension. On the Joker ground a cross-cut adit is to be run to tap the vein opened on the hill-top near the Union No. 9.——Six miles south of Manhattan, the Willow Spring district is active. Low-grade veins of considerable size bear both gold and copper.——Superior, a copper camp 20 miles north of Manhattan, is expected to make a good showing as soon as the snow leaves, allowing prospecting to continue.

Manhattan, Jan. 30.

A new double-compartment shaft has been started on the West End property. Machinery is in place with a capacity of 1,000 ft. in depth.——The Tonopah Extension may be forced to close down on account of lack of fuel. The Golden Anchor, McKane, and Red Rock properties of the same company have all been closed down. Ore is being stoped on four levels of the Tonopah Extension, but car shipments to Salt Lake are greatly delayed. The company claims to have 25,000 tons of milling ore on the dump, and a mill of 300 tons daily capacity is contemplated.

BRITISH COLUMBIA.

The heavy snowstorms and prevailing cold weather has handicapped the railroads, with the result that there is still a fuel shortage at Rossland. The shipments of the last week in January from the Centre Star were 780 tons; Le Roi, 2,105 tons, and Le Roi No. 2, 415 tons. The Trail smelter received 3,477 tons from the Kootenay camps during the week.—— The Granby company has kept four furnaces in operation, while the British Columbia and Dominion Copper companies have run one furnace each.—— An electric transmission line has been run to the Brooklyn mine of the Dominion company, and a 50-h.p. electric pump will be operated there. The mine is closed down, owing to lack of fuel. The Rawhide is still running, but the shipments are light.—— Only 35 men are employed at the Snowshoe, which ships ore to the British Columbia Co.'s smelter, and to the Trail smelter.—— The Little Bertha mine, on the north fork of the Kettle river, has been taken over by a company, with a capital of $375,000.——The Riverside group of claims has been bonded to P. J. Dermody for $60,000, and work has started. The Fern mine has been bonded to a syndicate of Spokane men. The property is equipped with a 10-drill compressor, a 10-stamp mill, a gravity-tramway 2,300 ft. long, an electric plant, and other accessories. Much stoping has been done above the 300-ft. level.

It is stated that a smelter will be built at White Horse. A company has been formed for this purpose, with a $1,000,000 capitalization.—— Reports indicate activity in the Salmo mining district. The Nugget mine has 200 sacks ready for shipment, and recently shipped a car of high-grade ore.—— The Kootenay Belle is working 10 men, and has a good showing.—— The Queen property is producing, and the mill is running steadily. The Emerald company ships three cars per week of lead carbonate ore. A carload of ore from the Ore Hill was recently treated at the Hall Mines smelter.—— The consolidation of the British Columbia Copper Co. and the Dominion Copper Co. has been considered by the directorates of these two companies, and the idea of forming an amalgamated company has not been abandoned. If this amalgamation is consummated it will

Map of Part of British Columbia.

mean that the new company will be of gigantic proportions, as the combined capital of the two companies now is $7,000,000, the British Columbia Copper Co. now having a capitalization of $2,000,000, while the Dominion Copper Co. has a capital of $5,000,000.—— The St. Eugene mine at Moyie has been closed down for two weeks, as no fuel is to be had. Very few men are leaving the camp, but there are no immediate prospects of securing coal.—— It is reported that the British Columbia Copper Co. will declare a quarterly dividend of 50c. per share in February, which means a return of 40% per annum on the par value of the stock, or 16% on the market price.—— The Granby mines have resumed work after a five-day shut down, due to lack of fuel. The smelter has been blown in at about half its normal capacity. A. B. W. Hodges, the manager, states that four furnaces will be kept in blast, as 1,000 tons of coke have just been delivered. The latest official figures show that the Granby mines turned out 801,404 tons of ore during the past year, an increase of about 22% over 1905.

Personal.

CHARLES BUTTERS is at Copala, Mexico.

W. H. WEED has gone to Santo Domingo.

WILLIAM W. MEIN is on his way to London.

ARTHUR R. TOWNSEND is at Telluride, Colorado.

H. H. WEBB is on his way back to Johannesburg.

J. P. HUTCHINS is at Boschland in Dutch Guiana.

THOMAS J. BARBOUR has returned from New York.

WM. L. COBB is examining mines in Durango, Mexico.

W. MURDOCH WILEY has left New York for Guanajuato.

JOHN CAMPION, of Denver, visited San Francisco this week.

MARK R. LAMB has been on a visit to Guanajuato, Mexico.

FREDERIC J. SIEBERT has returned to Los Angeles from Arizona.

PATRICK HARRIGAN has received an appointment in Alaska.

ROBERT V. NORRIS has recently lectured on coal mining at Harvard University.

J. R. FINLAY passed through San Francisco on his way from Nevada to Spokane.

PELLEW HARVEY & FELL have removed their offices to 62 London Wall, London.

JOHN HOGAN is the new foreman of the North Star mine at Grass Valley, California.

ALVA ADAMS, twice Governor of Colorado and thrice elected, is visiting California.

H. P. ROBERTSON arrived from Australia on the *Sierra* and has gone to Mexico City.

F. L. BOSQUI has returned from Colorado. He has an office temporarily at Berkeley.

F. DIETZSCH has gone to Russia in the interest of the Siberian Proprietary Mines, Ltd.

H. C. BELLINGER is to take charge of a copper smelter to be erected at Greenwater, California.

R. S. BOTSFORD is on his way from London to the Argentine, to take an appointment there.

R. C. GEMMELL has returned to Salt Lake from an inspection of mines at Yerington, Nevada.

T. H. OXNAM is inspecting mines near Humboldt, Arizona; he will proceed shortly to New York.

G. A. DUNCAN, of Denver, is opening up some mines in Eldorado cañon, in Lincoln county, Nevada.

W. H. STORMS has resigned as superintendent of the Yellow Aster mine at Randsburg, California.

THOS. J. JONES, mining engineer to the Mountain Copper Co., has returned to Keswick after a short visit to the East.

BENJ. B. LAWRENCE has been erroneously reported as Western manager—instead of consulting engineer—for the Lanyon Zinc Company.

ABBOT A. HANKS will remove his offices and laboratory back to San Francisco in March. The new quarters will be at 425 Washington St., opposite the U. S. Custom House.

R. W. FOSTER, manager for the Sevier Con. Mining Co., operating near Kimberly, Utah, has resigned. He has accepted the position of engineer for the Union Pass Mining Co., near Kingman, Arizona.

ROBERT W. HUNT & Co. have been appointed consulting engineers to the receivers of the Union Traction Co., Chicago, and placed in direct charge of the lowering of the car tunnels under the Chicago river.

It is reported that M. J. DALY, assistant manager of the Silver King mine at Park City, will shortly be promoted to the position of general manager of the mining interests operated under the control of David Keith and Thomas Kearns. He will be succeeded at the Silver King by WILLIAM BLOOD.

Obituary.

GEORGE H. EVANS died at Berkeley on February 4. He was taken ill suddenly and an operation on the gall bladder resulted fatally. His death has caused wide-spread regret in San Francisco, where he had a large number of friends. Born at Hull in England, forty-two years ago, he was a mining engineer in active and successful practice. His specialty was placer mining. He came to California ten years ago to take charge of the operations on the Golden Feather channel, at Oroville, succeeding Col. Frank McLoughlin as manager. This position he occupied for three years and then he became manager of the Banner mine, also in Butte county. Subsequently he traveled widely, becoming consulting engineer of various alluvial enterprises in Colorado, California, and elsewhere. He was one of the consulting engineers associated with the Risdon Iron Works. As a member of several engineering societies and of the Bohemian Club, he had a wide acquaintance, among whom a kindly disposition and cultivated manner made him always welcome. The engineering profession has lost a worthy member.

Dividends.

On February 4, the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 113 of $180,000. This makes the amount of dividends paid since January 1, $360,000, and total to date, $8,226,000.

New Flotations. — The Einasleigh Copper Mines. — The Anglo-Spanish Copper Co.—The Mount Cattlin.—Mineral Rights in Cornwall.—Large Capital to Be Invested.—Encouraging Outlook.—An American Syndicate in Cornwall.—Returns From Esperanza, Camp Bird, and Dolores.

Money being easier and January dividends being available, several new issues have made their appearance. The adoption of the old-fashioned prospectus would seem to prove that speculators' purse-strings are being loosened and that the public are again 'coming in.' Copper propositions predominate. One of the most promising of these is the New Einasleigh Copper Mines, Ltd., which has been formed, with a share capital of £200,000 to acquire a property in northern Queensland. The Queensland legislature has passed a bill authorizing the construction by the Chillagoe Company of a railway to the Etheridge goldfields that will pass within 12 miles of the mine. The property consists of 120 acres, and the purchase includes a lease of some 80 acres adjoining, which the company has the option of acquiring. The prospectus states that a main shaft has been sunk to 191 ft., and levels have been driven at 120 ft. and 170 ft. from the surface, proving in each instance the existence of an extensive body of copper ore. A blast-furnace of 50 tons capacity is on the property; but on the completion of the railway it will probably be more profitable to send the ore for treatment to the Chillagoe Company, with which negotiations are now in progress. It is said that the success of this flotation is already assured. With regard to the immediate prospects, it is reported that about 2,700 tons of ore averaging over 10% copper are lying at the mine and the ore proved about the 170-ft. level is estimated at over 36,000 tons of an average assay of about 10% copper. The ore carries an appreciable amount of silver and gold, which are collected in the matte.

The prospectus of the Anglo-Spanish Copper Co. is also advertised. The nominal capital of this company is £300,000, of which £110,000 is to be reserved for working capital. On the board of directors are found the names of Arthur C. Claudet and Andrew Johnson, late technical manager of Rio Tinto. The company acquires a lease in perpetuity of a valuable copper and sulphur property, situated in the province of Huelva, Spain, between the famous mines of Rio Tinto and Tharsis on one side, and San Domingo (Mason and Barry) on the other. The property consists of four groups of mines — the San Vincente, the Fronteriza, the Valrubio, La Carolina, and La Infanta, together comprising an area of about 444 acres, with an aggregate length of 5,100 metres, or over three miles along the line of lodes. Some £30,000 has already been expended in development on the San Vincente and Fronteriza mines, with satisfactory results, and in regard to these W. R. G. Rivington reports under date of October 2, 1906, that "5,000 tons of ore per month can be raised from the San Vincente mine within a short period of starting work. This tonnage, together with that raised from the Fronteriza mine, will enable 200 tons to be smelted daily, equal to 50,000 tons per annum, and will also, in addition, provide a further 100 tons of ore daily, making a total output of 80,000 tons for the first 12 months after commencement of operations."

Another copper mining company—Mount Cattlin—has just held its first stockholders' meeting. The chairman reported that the issue of the 200,000 shares of the company in November last was a satisfactory one, inasmuch as the whole amount was quickly over-subscribed, there being a number of applications from Western Australia—evidence of good opinion on the part of people who should be able to gauge the intrinsic value of the property. A cable from the consulting engineer, G. C. Klug, states: "Have located the three shoots of ore on the 200-ft. level. No. 1, 80 ft. long, 8 ft. wide. It contains 5% copper, 4 dwt. gold. No. 2, 80 ft. long, 6 ft. wide. It contains 3% copper, 2 dwt. gold. No. 3, 70 ft. long, 4 ft. 6 in. wide. It contains 2.5% copper, 2 dwt. gold. Preparations are being made to sink shaft; extending drift on the 200-ft. level, in order to develop country east and west. New air-compressors will be in full operation at the end of the month. Ore shipped to smelters to date, 1,264 tons, containing 67 tons copper, 261 oz. gold, 26 oz. silver. Gross value, £7,471; estimated net value, £3,808. 1,400 tons of ore on the dump ready and waiting shipment to smelting works. Selwyn Goldstein, late Great Boulder staff, has been appointed manager." Arrangements as to smelting have been made with the parent company, the Phillips River Gold & Copper Company.

The view expressed in my last week's correspondence as to the effect on the future of Cornish mining of the purchase by London financiers of the Tehidy 'lord's dues,' is receiving ample confirmation by local authorities. One of these, Mr. Herbert Thomas, is reported as saying that he thinks it is likely to be better, from the standpoint of the investing public, that the lord's dues should be held by business people who are heavily interested in Cornish mining ventures, than that they should be held by a private landowner, who has only invested a handful of money in the mines. Another statement (made in London), apparently from inspired sources, is to the effect that it is the intention of the newcomers to revolutionize mining in Cornwall, and their proceedings will be watched with extreme interest both inside and outside that county. One of their first steps will be to consign to the scrap heap some of the wretched stuff that in Cornwall goes by the name of 'machinery,' which is continually breaking down and costing in repairs more than it is worth. The newcomers will have no more corkscrew shafts, but will sink vertical shafts and drive direct to the lode. Great expense will be saved by such shafts in the items of hauling and pumping. They will also employ a far larger number of men than at present, and we believe they will get them if, as is stated, they are prepared to assure them regular employment and fair wages. The whole of the attention of the newcomers will not be concentrated upon the working of the mines, as the working of the market will also absorb some of their attention. There will be a rattling market for the shares, and encouraging reports will not be wanting. This is the sort of talk supposed to make Cousin Jacks sit up. Your correspondent can imagine some of them thinking, on contemplating such a glowing picture of what is to happen in the old county, that it may be less difficult to obtain "encouraging reports" than, at least in some cases, to "drive direct to the lode," even with the aid of vertical shafts and modern machinery.

The sale of his mineral rights by Mr. A. F. Bassett is still the subject of much comment and curiosity in western Cornwall. At an interview with a press representative, E. W. Meyerstein, of the firm that has acquired these rights, is reported as saying that the fault in the present working of many tin and copper mines in Cornwall was that the work was done on too small a scale. There was also a lack of modern machinery, some of the plant in use being from fifty to a hundred years old. With such antiquated plant the profits of the industry were so small that nothing was left for the landlord, who was entitled to dues upon the quantity of mineral sold.

In these circumstances the landlord would not allow the mines to be worked at all, if it were not that pumping operations were necessary. If one shaft was allowed to fill, the water would spread from one mine to another. Thus it paid the landlord better to let the mines be worked, even though he derived no cash benefit from them, than to permit them to remain idle. A company with a large capital would be formed by the new landlords, who would act in a sense as financiers to the various mines. The combined concern would represent the whole of the mineral rights on some of the most famous Cornish mines, including the Wheal Basset, Carn Brea, East Pool, a part of South Crofty, and the various streams in the Red river. Some of these concerns had paid no dues to the landlords for years, but the company to be formed would occupy a very different position from that of the landlords. For instance, any one of the companies might say that it was not in a position to pay its dues. The answer of the big company would be: "Very well; reconstruct your company, and we will, on terms, give you the financial aid you need in the way of adequate working capital." He cited the case of the South Wheal Crofty, in which his firm took an active interest. That mine was recently removed from the old 'cost-book' system of working, and was taken under the Limited Liability Acts.

The capital of the new company was £50,000. The machinery to be put into the mine involved an outlay of some £25,000, but the immediate result was that the company was able at once to step into a position of prosperity. The dividend for this year would be no less than 50% and for the following year 100%. The landlord thus came in for the dues which had been so long in abeyance. It was the success of this operation that paved the way for the more comprehensive scheme which was now being carried out. It is considered pretty certain that the new landlords will insist upon drastic changes at Carn Brea, and the public is prepared for an announcement in regard to East Pool. Several abandoned setts on the Tehidy estate will, it is thought, be taken in hand by the owners. Meanwhile a correspondent anxious about the labor question, sees in the royalty purchase an indication of a bright future for Cornish mining, but he points out that the labor question will become more and more difficult with the expansion of the industry, and contends that the mine-owners will best serve their interests by securing the services of Cornish miners for Cornish mines. He says: "There are hundreds out of work in the Transvaal who have no money to come home, the mail-boats being too expensive. I suggest that it would pay the syndicate that has purchased the Tehidy royalties to charter an emigrant ship to bring them home and give them work. A proportion of the men's wages could be kept back monthly until their passage money was paid." Meantime, while the local mines are advertising for men, miners continue to leave the country for foreign parts. R. Arthur Thomas, who presided at the first ticketing of the year, found several strangers in attendance, it is said, one of whom was a New York pressman engaged in writing up the boom! The quantity of black tin sold was 235½ tons realizing £25,998 at an average price of £110 10s. 3d. Anent the New York influence, it is announced that an American syndicate is buying up tin mines in Cornwall, and intends to spend £1,000,000 in their development. Among the mines acquired are said to be Balswidden and Consols, in the Wendron district, and Wheal, Speedwell, Rodney, Crabb, and the Virgin group in the Marazion neighborhood. In addition it is intended, if possible, to gain possession of several mines in the Camborne and St. Just districts. The name of the syndicate has not been published, but its agent, Edward Melville, has for some time been staying at Penzance, conducting negotiations. There is also some tall talk from the same source about the erection of tin smelting works near Marazion. An event of some importance may be noted in another part of the county—the ordering of an Elmore vacuum oil plant by the Clitters United capable of treating about 30 tons per day of pyritic copper-tin ore.

The Siberian department of the mining market has become somewhat steadier since the return of Mr. Orkin from St. Petersburg. The 'titles' scare, so effectively worked by the 'bears,' appears to have exhausted its force. On the other hand, it cannot be said that the news regarding the gold-mining results of the Orkin group is of such a character as to warrant even the present quotations of the operating mines.

Some of the American-managed mines on the London market continue to send reports calculated to maintain the interest of the speculating public. The December return of Esperanza (Mexico) shows that the mill ran 29 days and crushed 12,598 tons of dry ore; shipped to smelter, 4,338 tons of dry ore; estimated value of bullion produced, $145,186; value of concentrate, $74,609; value of ore shipped to smelter, $274,682; receipts from rents and other sources, $548; total, $495,125. The deduction of usual working and other expenses leaves a profit at the mine of $270,939. Shipping ore on hand, 529 tons. The manager reports that the amount of ore sent to the smelters is below the average, owing to the shortage of railway cars. He further reports that "development on the north end of the 5th, 6th intermediate, and 6th levels, on the West veins, is looking very well indeed, and in the northern portion of the mine the development of the San Rafael vein is showing up considerably more oxidized ore than was expected." In 1906 the total profit was £937,933; dividends amounted to £705,250. Thus, after paying dividends amounting to 31s. per £1 share, there is sufficient cash in hand to pay a further dividend of 10s. per share, with a substantial balance to carry forward. At the Camp Bird (Colorado), the mill ran 28 days in December and crushed 6,676 tons of ore, yielding 15,333 oz. bullion and approximately 651 tons of concentrate. Amounts received from sales of bullion effected during the month (including cyanide bullion), $238,216; concentrate (581 tons), $33,322; total revenue, $271,568; usual expenses, $55,664; surplus profit at the mine, $215,901. Feet of development work, 315.

Camp Birds were in demand on the market on the publication of the above-mentioned record return for December. In this connection the public has been reminded that the chairman, at the meeting held on September 7 last, announced that on the resumption of milling, high-grade ore would be put through the mill, thereby making larger profits than the average, so as to re-adjust the financial position as soon as possible. He cautioned his audience that such returns would be abnormal, and must not be regarded as average results. Following precedent, the news from Dolores (Mexico) is of less recent date. The returns for November are announced: Tons of ore treated, from the mine, 267; from tailing, 379; for cyaniding, 563. Total value of the production, $53,000; expenses, $23,000; profit, $30,000. From a review of the general situation at the mine, taken from the report of the new manager, W. H. Paul, dated December 6, it appears that the fourth (bottom) level was advanced in November 31 ft., and it looks as if it would be but a short time before the ore-shoot from above is cut. The manager thinks the third level is in the centre of the broken zone that showed for over 200 ft. on the main tunnel-level above. To remedy the recurrent difficulty as regards shortage of wood for fuel,

the manager suggests the possibility of water-power for the mill. He states there is a fall of 500 ft. vertical at the back of the mill, and that with the necessary plant, he believes there would be sufficient water-power to drive the mill for eight months in the year, if not longer. Apart from a shutdown of four days from lack of wood, everything has been running smoothly at the mill. Various improvements are in hand. Nearly all the concentrators had arrived and the remainder were due in about a fortnight. The additional tube-mill was ready at the makers and would be forwarded at once. The sand-plant had been put in commission, and the manager was considering the question of the most suitable place in which to install the Butters filters when they arrive.

Butte, Montana.

Bad Weather Impedes Operations.—Lessened Output.—No Copper in Storage.—Boston & Montana.—Butte & London.—Two Re-organizations of Doubtful Status.—Barnes-King Development Co.—Vigorous Exploratory Work.

Zero weather for nearly three weeks, a coal famine, and inability to get railroad cars caused a reduction of more than 6,000,000 lb. in the copper production of the Butte district in January. The total production was but 21,337,176, as against 27,491,420 lb. in December. Many of the mines had to suspend for several days at a time and three or four times during the month. The extreme cold weather froze the ore in the bins and on the cars so

that they could not be unloaded, and the long continuing storms blockaded traffic on the railroads so that nearly all the mines and smelters ran out of fuel.

The ore tonnage and copper production for the month was as follows:

Company.	Tons of ore.	Pounds of copper.
Boston & Montana	71,300	5,418,800
Anaconda	78,182	5,707,286
Butte & Boston	12,865	900,550
Washoe	11,501	865,070
Parrot	7,006	420,360
Trenton	14,291	928,915
North Butte	30,690	3,069,000
Coalition	24,800	1,785,600
Original	17,050	1,023,000
East Butte	3,782	340,380
Pittsburgh & Montana	4,030	314,340
La France	5,425	406,875
Miscellaneous	3,100	217,000
Total	294,022	21,337,176

The protest telegraphed to Attorney General Bonaparte by James Norton of New York against an alleged effort of a copper trust to run up copper prices by storing the red metal in various parts of the country, was not based on facts as far as Butte is concerned. He said 9,000 tons of copper were stored in Butte. At the time the statement was telegraphed there were not 400 tons of copper in the whole State of Montana. That fact was ascertained by careful investigation. It has been a fact well known in Butte, Anaconda, and Great Falls, where the big smelters are situated, that for a year copper has been loaded on cars and shipped before it had time to cool, and for more than a year there has never been on hand at any smelter in Montana more than one day's production. Daily shipments have been made when cars were available. During the severe cold weather in January and December, and the consequent car-shortage and tie-up of traffic on the railroads, the accumulation sometimes was of several days' production; but, aside from that, there was no copper on hand anywhere. If Mr. Norton's statement concerning other localities was as erroneous as it was about Butte, he will have some difficulty in furnishing the proofs which he promised the Attorney General.

Since the improvement in the weather the Boston & Montana Co. has resumed sinking in several of its large shafts. The Leonard shaft, a large four-compartment affair, is 1,260 ft. deep, and will be sunk to a depth of 1,400 ft. The big shaft on the West Colusa has reached a depth of 1,700 ft., where a station is being cut. It will be completed in a few days, when sinking will be resumed and the shaft carried to a depth of 2,000 ft. At that point the immense vein opened at the 1,600 will be crosscut and developed. The Colusa vein is 150 ft. wide and it is estimated that when thoroughly opened on the 2,000 there will be enough stoping ground to last the company for 10 years, and that the mine will be capable of yielding 1,000 tons of ore per day. All of the mines of the Boston & Montana have been yielding the usual quantity of ore since the cessation of the extreme cold weather which continued almost uninterruptedly for four weeks during December and January.

The head-frame of the Butte & London and the station at the 800-ft. point have been completed. This station is to accommodate the big pump, which occupies a floor-space of 13 by 48 ft. The present flow of water is not great, but an increased flow is expected with every vein that is cut. Report has it that the vein cut by the shaft between the 600 and 700-ft. points contains much better ore than was admitted by those in charge, and color is given to this by the fact that some of the miners familiar with the ground have been trying to secure a lease to work the vein, and the company has refused to lease on any terms.

A number of New York stockholders of the Butte & New York Copper Co. have been in Butte the past week inspecting the company's properties and the progress of the development work being done. The Butte & New York Co. was organized on a majority of the stock of the Butte-Milwaukee Co. and has assumed control of the property of the latter company. It is understood to be a re-organization of the Butte-Milwaukee Co., although the minority stockholders of the latter were not notified or consulted. The company owns the Pollock, a developed silver property; the Colonel Sellers, upon which the new company is sinking a deep shaft; the Bird, and an option on another claim known as the Narrow Gauge. Some of the New York men interested in the re-organization of the Butte-Milwaukee are interested in a similar re-organization of the Butte Copper Co., under the name of the Butte Copper Montana Co., the latter having recently been organized on a controlling interest in the Butte Copper Co. The minority shareholders of the latter company were given no chance to participate, and their status under the new company has not yet been explained to their satisfaction.

R. B. Lamb, general manager and consulting engineer for the new Barnes-King Development Co., has completed his working force for the mines, and it includes some of the most experienced gold miners in the West. Mr. Lamb, after a thorough examination of the mines, is satisfied that they can be made to yield 500 tons of ore per day. Special importance is attached to workings on the north end of the property, known as the Horse Shoe mine. More than 700 ft. of development work is under way there, and it is all practically virgin ground. From the main level a winze is going down in splendid ore, the body being regular and solid. Development is also in progress north and south on this level, and it is planned to erect an electric hoisting plant in a short time to hoist from below the 700-ft. level. A short distance from the Horse Shoe is the Mule Shoe mine, and another body of ore is being developed there. Stoping is going on from this point and the ore is shipped to the mill. Below the two mines mentioned a small silver vein is being developed. It carries close to $100 per ton, the ore being sacked. Above the silver vein an adit is being run, and $8 per ton ore has been encountered there. In the south end of the property the main development work is being done, and some good ore has been opened, but it will be necessary to go farther before the main orebody is cut. To handle the ore properly and economically from these workings, a new shaft will be sunk and deeper levels run. In the Santiago, which is situated still farther down the mountain, the orebody is proving to be all that was anticipated.

Salt Lake, Utah.

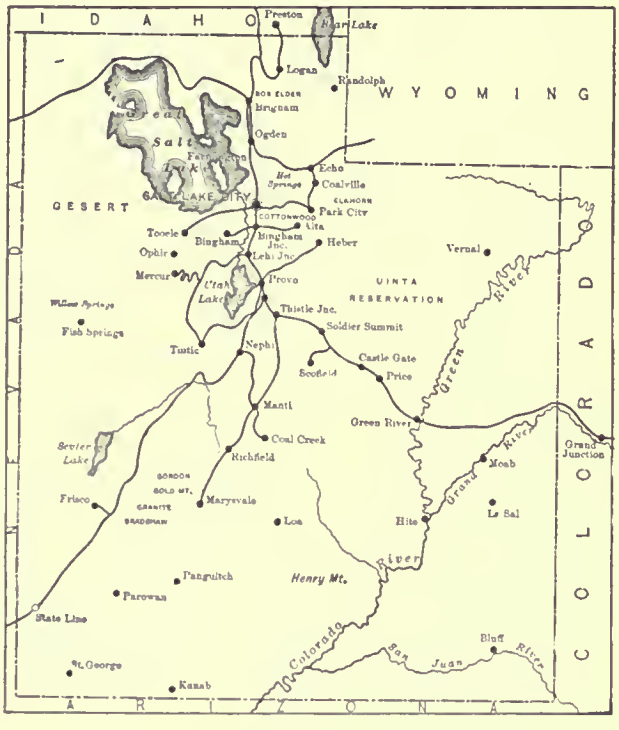
Dividends.—Shipments from Tintic.—The Grand Central-Mammoth Suit.—Good News from the Ajax.—Activity in Beaver County. Transportation Facilities Needed for Bingham.—Mercur Mill at Work Again.

Ten Utah mines paid dividends during January, the total distributions amounting to $1,193,000, as follows: Daly Judge, $112,500; Silver King, $50,000; Columbus Consolidated, $42,500; Yankee Consolidated, $15,000; Beck Tunnel Consolidated, $40,000; Grand Central, $15,000; Victoria, $10,000; Utah Mine, $3,000; Utah Consolidated, $900,000; Century, $5,000.

Nineteen mines in the Tintic district sent ore to the smelters during the past week, the total was 156 carloads, distributed thus: Ajax, 3; Beck Tunnel, 14; Bullion Beck, 8; Carisa, 3; Centennial Eureka, 53; Eagle & Blue Bell, 9; Eureka Hill, 6; Gemini, 10; Grand Central, 3; Ladede, 1; Mammoth, 12; May Day, 2; Scranton, 6; South Swansea, 1; Tintic Iron, 10; Uncle Sam Con., 2; Victoria, 5; Yankee Con., 6 carloads.——Another chapter has been closed in the now famous Mammoth-Grand Central suit, which has been pending in the courts for several years. The Grand Central brought an action against the Mammoth for title to certain mining claims and $300,000 damages for the value of ore alleged to have been unlawfully extracted therefrom. The case was decided in favor of the Grand Central in the State courts, whereupon the Mammoth company endeavored to carry it to the Federal Court on the ground that the Grand Central was a foreign corporation; but the application has been denied.——The installation of two electric hoists at the Lower Mammoth will be completed during the present week when the company will produce at the rate of 100 tons of ore daily.

Some interesting developments have been reported as having occurred on the 1,000-ft. level of the Ajax mine. ——An official of the Tintic Smelting Co. has made the statement that the breaking of ground for the proposed lead smelter, to be erected this year near Silver City, will begin some time in March. Water to be used for smelter purposes will be pumped from the Swansea mine.

The coal famine having come to an end, the management of the Cactus, in Beaver county, has resumed milling operations, after having experienced much annoyance. The plant is equipped to treat 1,200 tons of ore per day, and, if all goes well, the company should make money rapidly. The management of the Indian Queen mine, situated near the Cactus, has reported that two drifts from the main tunnel are showing shipping ore. L. N. Morrison of Salt Lake is manager.——The minority shareholders of the Blackbird Gold & Copper Co., which



Utah.

owns a large area of mining ground adjoining the Cactus mine, have brought suit to enjoin the company from selling the remaining bonds (amounting to $156,700) for ten cents on the dollar, to the president of the corporation, together with a stock bonus. At the late shareholders' meeting John E. DuBois was elected president.

The new tramway of the Utah Apex Mining Co. at Bingham is in operation after several weeks of vexatious delay. It is the intention of the company to increase ore shipments at once.——Suit has been instituted in the Federal Court against the Columbus Consolidated Mining Co., operating at Alta, the Government being the plaintiff. It is alleged that the mining company is occupying a portion of the public domain without proper authority. A restraining order is asked for, also judgment for $1,000 damages.

The matter of ore transportation from Bingham to the smelters is still a matter of anxiety to operators, notwithstanding the recent completion of the Rio Grande Western Co.'s second line into the camp. Without better motive-power equipment the railroad management will not be able to handle the traffic coming to it from the mines. The first unit of the Utah Copper Co.'s new mill will be ready for operation next month, but it is doubtful if the present transportation facilities will be adequate to keep it supplied. The announcement that the directors had decided to call a special meeting of shareholders to authorize an increase in the capital stock of the company 60,000 shares, the same to be alloted among present shareholders at $25 per share, came as a surprise. Additional funds are needed to complete the mill and power-plant.

Toronto, Canada.

Shipments From Cobalt.—Explorations in the Nipissing.—Other Exploratory Work in Progress.—Pyrites Deposits.—The Ontario Legislature.—Confusion in Names.

Reports of the shipments of Cobalt ore over the Temiskaming & Northern Ontario Railway will henceforth be made weekly. The shipments for the week ended January 19 amounted to 334 tons, by the following companies: Nipissing, 118 tons; Buffalo, 70; O'Brien, 62; La Rose, 61; Foster, 22 tons.——Testing by diamond-drill at La Rose mine to a depth of 383 ft., has established the fact that there is rich ore at that depth. It has therefore been determined to sink the shaft to the 400-ft. level and drive on the vein. Samuel Newhouse, W. R. Thompson, and other directors of the Nipissing will inspect the company's mine this week. The policy of the newly constituted board as outlined by Mr. Newhouse involves a systematic course of development and the installation of more machinery. It embraces the driving of at least three different main shafts with a complete cross-cut exploration to tap the large number of rich veins crossing the property.——The new machinery of the Erie mine is now being installed and a force of 58 men is at work.—— About 6,000 ft. of trenching has been done, and eight well-defined veins have been uncovered.—— At the Green-Meehan mine, 73 men are at work. A 40-ft. foundation is being prepared for the new boiler-house, in which two 100-h.p. boilers will be installed to supply power for the drills and hoists. Mining is being actively carried on along No. 1 vein, which has been opened for 315 ft. Veins No. 8 and 9 have been open-cut for about 40 ft. These workings are being covered, so that the weather will not interfere with operations.——A stamp-mill and concentration plant are being installed at the mines of the Cobalt Central Mines Co., where work has hitherto been done by pick and shovel, and the ore shipped in bulk; another big strike is reported at the Big Pete, owned by this company, at the 58-ft. level, where a blind vein has been exposed carrying 11,000 oz. silver per ton.——Contracts have been let for the sinking of shafts on the properties of the Coleman Development Co., on which three promising veins have been uncovered. Superintendent Leyson, of the Silver Queen, reports that a 7-in. vein of good ore has been struck on the 125-ft. level.——A large force of men is at work on four locations belonging to the Cobalt Union Mines Co., about five miles west of Cobalt, for the development of which comprehensive plans have been adopted.

The Northern Pyrites Co. has acquired possession of a valuable sulphide property lying north of Dinorwic on the shores of Vermilion lake in northwestern Ontario. Complete arrangements have been made for the development of the property for the supply of the New York market. E. R. Michie, the general manager, was in Dinorwic last week, arranging for the freighting to the mine of a large plant including two 65-h.p. boilers, a 12-drill Duplex compressor, and a saw-mill and machine-shop outfit. A spur line of about five miles will connect the property with the Grand Trunk Pacific Railway.

The Ontario Legislature was opened on January 24. The address of the Lieut.-Governor, outlining the legislation proposed by the Government, stated that a measure providing for the taxation of mining properties would be submitted. It also contained a warning against "hasty and reckless investment and speculation"—which will no doubt be universally approved and generally disregarded.——In consequence of the numerous complaints of the confusion caused by the similarity of the names of many Cobalt mining companies, the Provincial Secretary has ordered that the Lawson Cobalt Silver Mining Co. and the Kerr Lake Lawson Mining Co. shall each adopt a new name.

Labor is inferior at Cobalt, but wages are good. Pick-and-shovel work is paid for at the rate of $2 and board, miners get $2.50, and machine-men $3, with board. Board costs about $4.50 per week. Sinking is done by contract, prices averaging from $18 to $35 per foot according to the depth. After 40 ft. the windlass is removed and a steam-hoist (costing $750) is employed. A steam-drill is often added, at a further cost of $250. Only a few contracts have been made for over 40 ft., at which depth a shaft must be timbered.

The latest strike of rich ore is in the Temiskaming in Lot I Concession III Coleman, a portion of the district which up to a week or two ago was not considered very important. Such rich bodies of ore are coming to light in different portions of Coleman, Bucke, and Lorrain, wholly disproving the early theories and extending the silver-bearing area to approximately 50 miles square, leaving, of course, many undeveloped square miles in between. The Larder Lake excitement bids fair to be a permanent gold camp. The Temiskaming & Northern Ontario Railway is considering a line from Englehardt to Larder Lake, and the spring will bring a rush of gold-seekers to the region. While every one is intent on finding quartz veins, the alluvial is being overlooked.

Leadville, Colorado.

Homer Shaft to Be Sunk.— Extension of Ore Measure.— Important Development on Breece Hill.— Horseshoe District.— Mammoth Placer to Resume.

During the fall of 1906, developments in the Coronado workings proved that the great ore-shoots of this property dipped rapidly toward the west, and in consequence the theory of the late Henry Higgins has again come into prominence. Mr. Higgins attempted to put his theory into practice by sinking the Homer shaft about a mile and a half west of the city, but water put an end to the project. Recently local capitalists have completed arrangements to sink this shaft to the first contact. It is estimated that $200,000 will be required to buy the necessary equipment and sink the desired depth. The machinery will include a pumping plant larger than any of similar character now in operation in the district, and the development work contemplated by the new company will probably settle the long mooted question of ore-shoots west of the city.

More than twenty years ago a shaft was sunk on the Jaybird property, near the head of California gulch, to a depth of 185 ft., and abandoned, as no pay-ore was discovered. Recently Dr. J. J. Cook, the owner, granted a long lease to A. Sandusky and F. Bochatey, who continued the shaft but a few feet when a body of sulphide ore was discovered, carrying high values in gold, silver, and copper, and approximately 24% zinc. A shipment is now being made as a check on the assays obtained from smaller lots.—— Not since the discoveries in the Little Johnny and Printer Boy properties has so much interest been aroused in the Breece Hill district as has resulted from the late discoveries made in the President. The properties lying in Big Evans gulch on the trend of the new shoot are making active preparations to sink to the contact that carries this shoot. The ore resembles that from the Little Johnny in character, and the direction of the shoot leads many mining men to conclude that it is an extension of it; therefore, the strike is being watched with unusual interest.

The Mount Harvard claim, which for the past twelve years has been undergoing development, has at last entered the list of producers. The owner cut a four-foot

vein of unusual richness, and of good size, as indicated by the work done in the past two months.—— Reports from the Horseshoe district indicate a lively campaign just across the Mosquito range from the head of Iowa gulch. The lessees of the Clover group report a 14-ft. vein of quartz running well in both gold and silver; also the Madsill, under lease to W. H. Powless, has opened up a large shoot of good mill-ore.

The important announcement has been made that the Mammoth placer in Big Evans gulch will soon resume operations; in fact, work is now well under way under the direction of the manager of the new company, J. A. Murray. It will be remembered that last year a shaft was sunk that opened up an unusually rich orebody, but the lessees forfeited their lease by not being able to cope with the large body of water. The new company is styled the Leadville-Wellington Bonanza Mining Co., and is composed of Boulder county capitalists. Excavation has been started for a large power-plant, a 10-in. water-column is being installed, and electric turbines will be employed to generate the power. The resumption of work on the Mammoth means a great deal to Leadville, since the known body of high-grade ore, which was explored by Major Bohn for the old company, proves the extension of the Breece Hill ore-shoots in this direction, and means a much larger area to be included within the Leadville gold belt. —— A strong company has been organized to develop the Arizona placer, embracing 160 acres, and located on Empire hill, eight miles from Leadville. The work of cleaning out the old workings, which were abandoned 28 years ago, has begun. The main shaft was sunk but a few feet when a strong shoot of carbonate ore, running 65 oz. in silver, was uncovered.

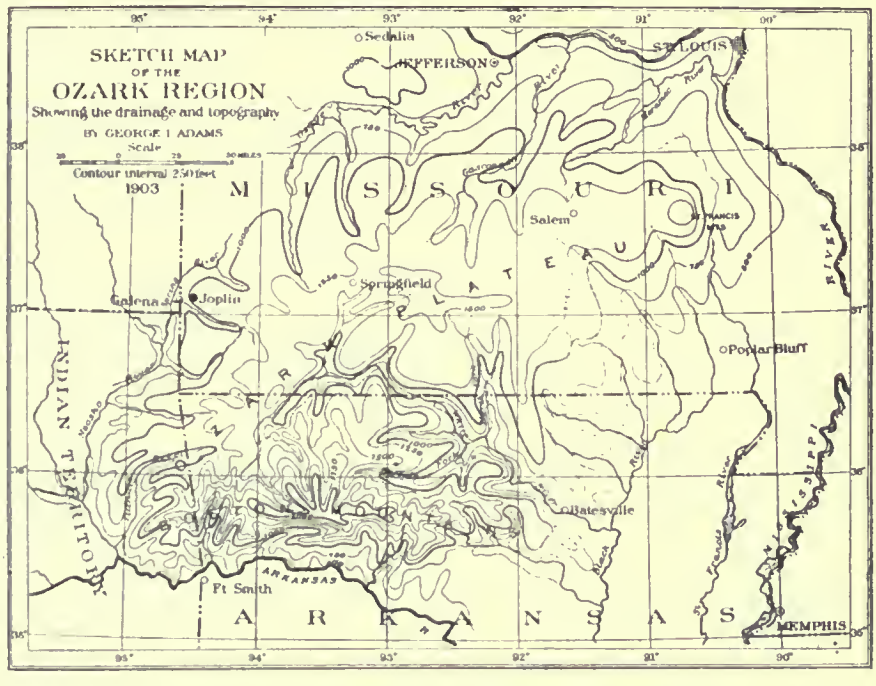
Joplin, Missouri.

High Prices for Zinc and Lead Ore.—Shipments for the Week.—Several New Strikes.—Activity in Prospecting.—New Companies Organized.

The highest price reported paid for zinc ore last week was $51 per ton for the ore from the Greencastle mine on the land of the Rex Mining & Smelting Co. and the ore from the Temagami on the land of the Continental Zinc Co. It was reported that $52.50 was paid for some ore from the Missouri Lead & Zinc Co.'s land, but the report could not be verified. Lead ore continues to hold strong, advancing a little every week, $88.50 having been paid last week and with each week the prospects for $100 lead grows more encouraging to producers. Last week the Galena Smelting Co. of Galena, Kansas, sold their smelter to the Hammar Bros. White Lead Co. of St. Louis, which may be an advantage to the lead producers and help raise the price. This smelter has been closed down for the past several months but the new owners will re-start the plant as soon as arrangements can be made to do so.

The shipments last week were: Zinc ore, 11,201,360 lb., valued at 258,213; lead ore, 1,539,330 lb ,, valued at $65,437; combined value $323,' 50. Compared with the previous week it was an increase of 1,838,940 lb. zinc ore and a decrease of 38,390 lb. lead ore, and an increase in value of $12,652. It was also an increase in value over the same week of 1906 of $70,510. The total January sales of 1907 mark an increase of 757,050 lb. zinc ore and 655,150 lb. lead ore, and in value $74,253, over the January sales of 1906.

The Old Times Lead & Zinc Co. of Joplin has purchased the lease on the Superior mine and mill on the Leonard Realty Co.'s land at Chitwood, which has been owned by Eastern capitalists. There is only one shaft at present connected with the mill but it is understood that the capacity of the mill will be doubled and tramways constructed connecting it with two or three other shafts in which pay-ore has been found, and in this way keep the mill in steady operation.——The Ishpeming Mining Co., operating at Sherwood, has made a new strike of zinc ore and now has a 16-ft. face from which to work on.——The Alpha Mining Co. operating at Spurgeon, south of Joplin, has been making a splendid showing for several months.



Map Showing Position of the Joplin District.

Activity in prospecting mineral lands southwest of Jasper is being resumed. Coal is being hauled to the Schmuck land, where some prospecting was done and some free ore encountered in a shaft that was sunk to a considerable depth. Preparations are also being made to resume work on the Rice land in the same vicinity where prospect work was done with some promise of success.—— A new shaft at the American Beauty mine on the Underwriters Land Co.'s land north of Webb City is now down to 110 ft., which is within 10 ft. of the orebody as shown by the present hoisting shaft.——The Black Cat mine, on the Guinn land north of Webb City, has temporarily shut down for the purpose of making some needed repairs to the mill and while this is being done development work will be pushed.

The Last Chance Mining Co. composed of Otto Gosch, W. S. Marquiss, and Roy Hilburn of Webb City, operating on a lease on the Chinn land at Prosperity, has made a rich strike of lead ore by drill. They have penetrated 22 ft. of ore. This lease is located just east of the General Lead & Zinc Co.'s lease, one of the best leases in the entire district. A shaft will be started at once and if the property proves as good as the drill-cuttings a mill will be erected in the near future.——The S. W. Prospecting Co. of Joplin has filed articles of association with a capital stock of $30,000. The same parties have organized the L. W. Mining Co. with a capital stock of $50,000. Sidney L. Wilkins, W. S. Bartlett, and J. W. Perry all of Joplin are the stockholders.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE specific gravity of a substance is its weight as compared to the weight of an equal body of pure water.

THE celebrated metric bar serving as an international measure, preserved at Paris, is of platinum, with 10% alloy of iridium.

In using hemp ropes, the bowline is one of the most useful knots, as it will not slip, and it is easily untied after being strained.

IN corrugated iron, both for roofing and siding, corrugations 2½ in. wide by ½ or ⅝ in. deep are recognized generally as the standard size.

AN easy rule-of-thumb to remember in estimating the weight of material, is that a sheet of iron one foot square and one inch thick weighs 40 pounds.

THE stamp-cam curve is an involute of a circle, the radius of which is equal to the distance between the stamp-stem and the cam-shaft, centre to centre.

AN act of the Congress passed in 1893 established a standard gauge for sheet iron and steel, which is based on the fact that a cubic foot of iron weighs 480 pounds.

EVERY triangle has six parts—three angles and three sides. When any three of these parts are given, provided one of them is a side, the other parts may be determined.

THE weight of common loam, shaken, is from 82 to 92 lb. per cu. ft.; that of dry gravel or sand, 90 to 106; and that of sand, perfectly wet, 118 to 129 pounds per cubic foot.

ONE square of roof, means 100 sq. ft. of surface. Using pine shingles, if four inches is exposed to weather, 900 shingles will be required, weighing 216 pounds; while if six inches is exposed, only 600 shingles will be required, weighing 144 pounds.

IN English practice, cable-traction ropes are commonly made with six strands of 7 or 15 wires, while in the United States, strands of 19 wires are generally preferred as being more flexible. Much of our hoisting rope is made on the latter plan.

PLOUGH-STEEL ropes are made from a very high grade of crucible steel, having a tensile strength of from 100 to 150 tons per square inch. This rope is used for long ropes where the reduction of the dead weight of the rope becomes a matter of serious consideration.

COBALT, in the form of smaltite, is being obtained at the Standard mine, in Grant county, Oregon. A concentrate containing 15% cobalt and 10 oz. gold is obtained, but in small quantities. The ore affords an interesting problem in concentration, as it contains native gold, smaltite, and chalcopyrite.

IN spite of the apparent inaccuracies of the method, the crucible assay continues to be used almost entirely in the determination of lead. Most of the smelters buy on the basis of crucible-assay returns, and the wet method, although far more reliable, is seldom seen in use in the field.

A FEW YEARS AGO it was predicted that a high price for copper would bring aluminum or an aluminum-copper alloy into successful competition with copper, in the manufacture of the wire used in transmitting electric power. This has proved a delusion. The output of aluminum is too restricted to enable it to replace copper, the demand for which has overtaken the supply.

MOUNT BISCHOFF tin mine, in Tasmania, has returned £2,079,000 to its shareholders. The discovery was made by James Smith in December, 1871. In 1873 the present company was formed with a capital of £60,000, of which only £29,000 was called up. In February, 1877, the first dividend was paid and since then the profits have been distributed each month with marvelous regularity. At present the average ore yields 2.75% tin.

A METHOD in use in diamond-drilling in the copper district of Michigan, for determining the dip of the drill at the bottom of the hole, consists in lowering a glass tube partly filled with hydrofluoric acid. A duplicate tube, similarly filled, is kept at the surface, and when the acid has etched a well defined line marking the angle at which the surface of the liquid rests, the tube is withdrawn from the hole, and the dip read directly, by means of a protractor.

IN reply to the question as to who has the best right to the mining claim, wherein *A*, in January, 1905, locates the claim and has the location work done, but does not record it with the district mining recorder (though but a short distance away); and then near the latter part of 1906 he (*A*) arranges with a contractor to excavate about 280 cu. ft. of work on the claim (where it was all easy picking and shoveling ground, and where he would not need to blast) for $100; and the contractor commences work there on the last day of 1906 and quits on January 3, 1907, and moves off the claim January 4, 1907, taking away all of his tools, claiming that he had performed his contract and was done with it. As this work did not quite fill his contract as to the number of cubic feet, and could have been done by a first-class worker in less than two days' work of eight hours each, then comes *B*, after the contractor had moved away, and locates the claim on January 4, 1907, claiming that but a very small part of the annual assessment work was done for 1906. Which has the better right to the claim? The contractor had to come 60 miles to do the work, and return home when it was done, and he only did from two to three days' work on the claim for his $100, which it was agreed should be paid him for a certain amount of cubic feet excavated in loose or picking ground.

The facts recited in this communication do not present a question upon which the MINING AND SCIENTIFIC PRESS should venture an opinion except in so far as it might possibly involve the application of general principles of mining law, and we shall content ourselves with a simple statement of these principles: The value of assessment work is not to be determined necessarily by the contract price or the amount paid. These may be elements entitled to consideration, but are not necessarily controlling. The question simply is: What is the reasonable value of the work done, considering the local environment? The remoteness of the claim and the time and expense necessarily involved in reaching it, where the camp is inactive and labor is not obtainable, may under certain conditions be considered in estimating the value of the work. A mere expenditure is not sufficient. The work must tend to develop the claim and be of the reasonable value claimed. The burden of proof to establish non-performance of the work rests on the party asserting forfeiture. Where there has been work done and done manifestly in good faith, judicial sympathy rests with the original discoverer as against the 'jumper.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Treatment of Slime.

The Editor:

Sir—The attack upon the slime-treatment problem seems of late to have been worldwide and during the year 1906 crowned with a large measure of success, through the various devices for vacuum-filtering brought out up to that time.

Having been greatly interested in the matter bearing on the subject, published in your journal since Mr. R. Gilman Brown's paper in the issues of September 8 and 15 last, and having had somewhat of a struggle with the same problem a few years ago, which resulted in the design of a horizontal revolving filter continuous in its operation, I venture to step across the somewhat indefinite boundary dividing the domains of the mining and civil engineer, not however without some trepidation engendered by the oft repeated question, "Who is a mining engineer?"

The design referred to was made for a company that became financially embarrassed, and during a long period of re-organization the mill was shut down and the filter not installed. Pressing calls on my time in other directions have prevented systematic efforts for its introduction in other localities, hence it lacks the interest derived from actual operation under working conditions.

In general, it consisted of a shallow tank carrying a filter of canvas and cocoa-matting resting on perforated boards a few inches above the bottom of the tank, which is attached to a cast-iron hub revolving around a fixed hollow central pedestal. The weight at the centre is supported upon ball bearings, and at the periphery upon wheels running on a circular track. The space between the filter and the bottom of the tank is divided into a number of compartments by radial partitions, air-tight with respect to each other.

A portion of the hollow pedestal is connected by a pipe, through the bottom, with a vacuum-pump and forms the vacuum-chamber communicating, through openings in the hub, with the compartments beneath the filter. In the vacuum-chamber there is a valve-box and valve arranged to automatically cut out each compartment successively from the vacuum and admit to it compressed air to loosen the cake and aid in keeping the filter open. The cake is removed mechanically over a scraper at the end of each revolution and the cleaned surface of one sector presented again for the onflowing pulp. The canvas surface of the filter is protected from damage by the scraper by being covered with coarsely perforated steel or thin steel strips. The top surface of the filter is plane, without projections to interfere with the operation of the scraper. To prevent the flooding of the whole filter, light radial plates, adjustable vertically but fixed horizontally, divide the space above it into a suitable number of compartments; these plates are made reasonably tight against the moving sides of the tank by rubber or strips of canvas easily replaced when worn out. There is virtually then a series of stationary compartments above the filter, containing different depths of pulp under which the filter is passing.

The pulp is delivered from a fixed launder upon the slowly revolving filter and is subjected to the effect of the vacuum during about seven-eighths of the revolution and to the compressed-air and cleaning one-eighth. At occasional intervals it is easily and thoroughly washed out, by turning solution into the compressed-air channels and reversing the currents through the filter, the solution used in the washing being immediately returned to its proper channel through the vacuum-chamber during one revolution.

Whether the washing of the slime can be accomplished in the revolution or not, needs some further investigation. The present design contemplates the use of a second filter with the addition of the wash-water and agitation between the two filters. Without going into further details, which will be cheerfully furnished to anyone so desiring, it may be said that the mechanical arrangement is very simple, and provision is made for the ready replacement of wearing parts.

The change in the older methods of slime treatment to the vacuum-filtering is based mainly on the use of vertical groups or a 'basket' of filters, no filter of the horizontal-revolving type, so far as I am aware, being in use in the United States, although the Ridgeway revolving filter is stated by Mr. Alfred James (in your issue of January 5, 1907) to be in successful operation at Kalgoorlie, and an installation of a 500-ton plant is now under construction at the Great Boulder mine.

While local conditions may have required the adoption of the 'basket' type, it does not appear that the mechanical elements of the general problem have been met in a scientific manner. The intermittent character of the work done involves the application, at intervals, of relatively high-powered appliances for use during short continuous periods. It may be said that the use of 10 horsepower for two hours consumes no more power than the employment of two horse-power for 10 hours, but the larger plant involves the greater capital outlay, with its interest, which is a legitimate charge against the cost of operation.

The vertical 'basket' is immersed in a tank of pulp and during the filtering operation agitation is necessary to raise the particles of higher specific gravity up to the filter and, further, lifts are installed to pour the pulp taken from the bottom of the tank over the top of the filter; both operations tending to produce currents in conflict with those generated by the flow of the filtrate through the filter, thereby retarding the accumulation of the solids and causing further capital outlay, additional consumption of time and cost of operation. For the settlement of this finely divided matter in suspension, freedom from agitation is usually regarded as essential; but here the particles moving vertically must be seized by the inflowing currents as they pass and held by the expenditure of sufficient force to produce the adhesion, the aggregate vertical component of which must equal 18 tons in the case of the Standard company's plant at Bodie. This, it seems to me, must be much greater than would be necessary in a horizontal filter, where the application of the force should be just sufficient to produce the desired separation of the liquid from the solids and produce a minimum compression of the latter consistent with the removal of the desired amount of moisture, while in the vertical filter a maximum compression would seem desirable to furnish the necessary adhesion. In other words, gravity would aid continually in the accumulation of the cake in the one case and would be working in conjunction with the atmospheric pressure, while in the other the applied forces of the vacuum and agitation are working in conflict with each other and with the natural force.

The lifting, transfer, washing, and final discharge are all operations requiring the expenditure of power increased by the intermittent character of the work. As an offset to these features, it is true, there is obtained a very large surface for filtering. This in itself renders necessary the maintenance of the vacuum against the increased filter-surface; and the question naturally arises

whether it is not possible to spread out, as it were, the whole operation, or instead of taking it in chunks at long intervals, to take it in smaller pieces at uniform short intervals, or making the intervals short enough, continuous, and at the same time utilize the important element of gravity.

Again, the introduction of any considerable quantity of sand not ground to the requisite fineness interferes materially with the adhesion of the cake to the surface of the filter, and were it not for the necessity of the extremely fine grinding to insure the success of the filtering operation, it is highly probable—from the point of view of satisfactory extraction of values alone—a point in the fine grinding might be reached at which it would be more profitable to discontinue the attempt to reduce practically all of the product to the 150 or 200-mesh size and allow it to pass with a larger proportion of coarser material. The interference of the coarser material with the successful operation of the vertical filter is illustrated in Mr. Nutter's paper, in which he says that at a time when the tube-mill was out of commission "the Moore plant limped along as best it could without re-grinding."

On a horizontal filter the admixture of sand would have the effect of rendering the cake more permeable and facilitate the operation without in any manner interfering with the handling of the residue. In fact, the admixture of a suitable amount of sand to the pulp as it reached the filter might be found to be a positive advantage.

The important element of cost of installation, as far as can be learned from these recent publications, is as follows:

The Standard plant is stated by Mr. Brown to represent a cost of installation of $60,000, although with the knowledge now available it could be duplicated for $45,000, or approximately $450 per ton of capacity. The interest on this outlay would be $2,700, representing a charge of 7½c. per ton on a basis of 3,000 tons per month. Mr. Bosqui gives the cost of installation of the Merrill plant as $300 per ton of capacity and the cost of the plant as $400,000, representing an interest charge of slightly in excess of 4c. per ton on a basis of 1,600 tons per day. I have not seen an estimate of the cost of the Butters filter.

The estimate of the cost of installation of a horizontal type, using two filters, one for the direct operation of filtering and the other for the washing, will not exceed $10,000 for a 100-ton plant, $100 per ton of capacity, with an interest charge of 2c. per ton. This cost would probably be reduced by local conditions, the amount of power that could be furnished by the existing power plant of a mill, and other considerations.

The Moore filter is pronounced by Mr. Bosqui to be the origin of the great change produced during the year 1906 in the treatment of gold ores by the cyanide process, and the basket type of filter receives the endorsement of men of pronounced eminence as specialists in the particular line to which these devices pertain, strengthened by increased recovery over methods heretofore in use. Great as has been the advance, I have ventured here to draw attention to a few considerations, from the rational point of view as distinguished from the practical, that appear to me to have a bearing on the economical features of atmospheric filtering.

EDWARD PARRISH.

Newport, R. I., January 12.

AT Tombstone, Arizona, there are represented three types of ore deposit, within a limited area, namely, 'true fissure' veins; 'blanket' veins, in the bedded limestone; and a huge mineralized dike, often 50 feet in width and traceable for nearly a mile.

Homestead and Timber Entries on Mineral Land.

During the past two months many complaints have been received by the State Mineralogist, Mr. L. E. Aubury, from miners stating that mineral lands were being entered in northern California by homestead and timber entries and that the miners' rights were being infringed upon. The timber speculator is again busy in Siskiyou, Del Norte, and Trinity counties. In Tuolumne county, homestead entries are being made on the Table Mountain channel. This channel is well defined and millions of dollars worth of gold have been extracted from it. The overlying formation of this channel (scoria) is of such a nature that it is impossible of cultivation and is not even fit for grazing purposes, and the boldness of those who attempt to acquire this land by other than mineral entry, illustrates how little regard speculators pay to the oath (required in making such entries) that the land is non-mineral in character. On account of similar practices, President Roosevelt issued a recent order to all United States Land Offices in California directing that where applications are made for patent, the land must first be examined and reported on by a Government officer.

Complaints have also been received by the State Mineralogist from Mariposa and El Dorado counties where homestead and timber entries have recently been made on mineral ground. Mr. Aubury, in speaking of the matter, stated that he had secured the names of many persons who had made false entry, with a description of the land, which it was sought to grab from the miner, and he has placed the information in the hands of the officers of the U. S. Land Office. The persons making this class of entries will probably be allowed to take the non-mineral affidavit oath at the U. S. Land Office in their district, and after committing the perjury, will be arrested and arraigned in the U. S. Courts, and examples will be made of them.

The State Mineralogist has also received many complaints from miners in Kern, Inyo, San Bernardino, and Riverside counties about the large number of claims that have been located by one person. In Death Valley, one man has made over 350 locations, and in Greenwater, one man has located a territory about ten miles in length. In all the counties mentioned, other than those noted, the locations made by one person vary from 40 to 200.

While recognizing the greed of some of these locators, Mr. Aubury says that under the present laws operative in this State, there appears to be no remedy. If the locations are made on mineral ground and the claims properly staked, and notice of location posted on the claim, the locator can hold them. Further, it is not even necessary for him to record his claims under California law, so the real prospector is shut out. Mr. Aubury says: "The only way that I can see to overcome the difficulty is to make a change in our mining laws, and I am heartily in accord with and favor a law that will be similar to the present Nevada law. Every locator of a lode-claim should be forced to properly stake or monument his claim on discovery. A copy of his first location notice should be filed for record with the District or County Recorder within 30 days. He should then be allowed 60 or 90 days in which to sink a shaft 4 by 6 ft., 10 ft. in depth, or a tunnel, drift, or cut, equal to the same dimensions, this work to be performed only where evidence of mineral exists, and *not in the softest spot to be found on the claim*. This should also apply to gold-placer claims, in so far as the work should be performed on an exposure of gravel or gold-bearing material, excepting where there is unquestionable evidence of a buried channel. After work is done, the locator should file for record his proof of labor and final notice.

Cornish Tin Mining.

Written for the MINING AND SCIENTIFIC PRESS
By H. E. WEST.

'Copper, Fish, and Tin,' these form the significant trade-mark of the county of 'One and All.' Cornishmen are fishermen, and Cornishmen are miners. Copper production had almost ceased, fish had become a diminished item, and tin production had so fallen off that from Dartmoor to Land's End only a few mines remained working, and of these only the very hardiest maintained dividend payments. The St. Just district had but one active mine, namely, Levant; St. Agnes had Wheal Kitty; Camborne, Dolcoath, and some half a dozen others; St. Austell, Clitters Ltd.; Redruth, that old centre of mining, not one.

The ancient industry was all but doomed when, after some significant signs during the past few years, tin bounded to over £200 per ton and carried Cornish mining upward with it. Again is the ancient industry rejuvenated; the hearts of the 'adventurers' take fresh courage, as over the length and breadth of the land there is an awakening of hope; old 'setts,' long abandoned, are again being equipped for production.

Just how far this marvelous revival is likely to go is hard to say. It is almost incredible to those of us that have seen mine after mine abandoned, and this old county denuded of its hardy workers; we cannot realize the complete renewal of this industry, yet, with tin at £150 per ton and over, all things are possible. Mines died, not because they were worked out, but because, with tin at £60 per ton or less, they could not be made to pay. No mine in Cornwall is down to 3,000 ft. vertical; Dolcoath approximates this, but most of the workings are comparatively shallow.

Men who are competent to form an opinion say that tin will remain over £150 per ton for some time. The production is inadequate to the demand, hence the rise and continued high price of the metal. Fully two-thirds of the world's tin supply comes from the Straits Settlements and Dutch East Indies, where the mining is entirely alluvial. There is said to be little chance of any large increase in supplies from these deposits. Australia and Tasmania are not large producers. In the United States, Alaska has the only promising tin region. Bolivia has a large area traversed by tin-bearing lodes of phenomenal richness, but the mines are inaccessible to railroads at present, and the difficult transport—principally packing by llamas—limits production. A large and sudden increase of tin is deemed, therefore, practically impossible, hence the maintenance of the high price of tin and with it the hopeful outlook for Cornish mining.

Cornwall is the oldest tin-producing region in the world. The industry probably dates from several centuries before the Christian era. The isles of Scilly, off its coast, were known as the Cassiterides, or tin islands.

A Group of Cornish Tin Mines.

Market Jew, or Marazion, was the market for tin, and St. Michael's Mount was the shipping port in the days of the Phœnician triremes. So much for those far-off days. From then until now the mines have been worked. Forty years ago, or perhaps a little more, Cornwall was in the heyday of its prosperity. Today empty engine-houses are silhouetted against the sky-line of her hills, or silent ruins stand embowered in her valleys. The 'bobs' no longer beat as ceaselessly as the clock-tick, and, indeed, in all but a few instances, they have been dismantled and have gone into the scrap heap; the quiet of desolation is supreme. And this is the picture of the times it is proposed to quicken into life, and all because tin is over £150 per ton. Cornishmen have always taken a world of beating, and the sons are equal to their sires. The proposition is by no means hopeless. There are areas of tin-ground yet unprospected, most developments are of shallow depth, none are so deep but that they might be doubled—conditions being equal. Improved dressing plants have rendered complex ores of tin amenable to treatment.

Cornishmen are proverbially conservative. There

seems a fatuity about the place and the men, who abroad are alive to every improvement and up-with-the-times, and who on their return to their native county, bow to the inevitable and tread in the well-worn footsteps. Big things can be done with a good balance at the bank—nothing without it. The cost-book system of the past expected much of its manager and gave little. This factor, more often than not, is accountable for the backward state of equipment at the mines. Managers were afraid to increase expenditures on a struggling mine, and at times were denied absolute necessities. Vigorous exploitation cannot be undertaken with a depleted cash-box, and exploration costs money. When developments fall behind and the mine can barely be kept alive by returns, without capital to prosecute developments, the fate of that mine is dismally certain. Now all this is being changed, limited liability companies replace the groups of adventurers, working capital is forthcoming, and equipment will be provided, in most cases new. The mines are in a position to get modern and efficient machinery.

Power is the next item of importance. There is talk of a central station for the generation of electricity. The centralization of the generating plant and an efficient system of distribution is the secret of cheap power. A central station situated on the seaboard, using coal and gas engines, could doubtless supply the whole of Cornwall—with a trunk line 20 miles long, three-phase system, carrying 40,000 to 60,000 volts, and on a basis of 10,000 h.p. minimum—at a cost not exceeding $75 per h.p. year. Synchronous mill and compressor motors, with motor-driven multi-stage centrifugal pumps, would do much toward the cheapening of power charges even at two or three times the above quoted figure. Such things are accomplished today in Mexico, and on no mean scale. Why not in Cornwall? Coal can be landed at 75 cents per ton above the price at the pit-mouth, and in quantity.

Here follows a brief review of the past and present equipment of Cornish mines. The Cornish pump is universal; the huge beams of 20 tons or more, with steam cylinders up to 100 in. diam., and the large wooden, or more modern iron, pump-rods with the cumbersome and costly equipment of pump-lifts and balance-bobs down the shaft, should nowadays be relegated to the past, even as the old Cornish stamps, with their ponderous stamp-axle, square lifters or stems, and cast-on heads, have made way for the high-duty Californian type; and as the classic 'buddle' has been supplanted by the several forms of percussion and shaking tables. Much improvement yet remains in the concentration, termed 'dressing,' of the ores. More gradual reduction, magnetic separation, and comprehensive slime plants should raise the percentage of extraction. The last feature should be especially developed since, on account of the intimate association existing between cassiterite and its gangue, comminution of the particles is essential, and the fact of the sliming property of cassiterite thus finely ground being almost incapable of settlement in water within a reasonable distance and period. Tin 'capel,' as the tin ore is called, is usually very hard, but gradual reduction through breakers, rolls, and stamps, would efficiently perform the coarse crushing and reduction; and tube-mills might prove serviceable for the finer grinding of the middling, or 'whits.' Belt equipments for the handling of ore and tailing, when, in the latter, sluicing is not adaptable, would cheapen the cost of handling.

Tin veins rarely occur out of the granite, or far from its contact with 'killas,' or slate, in Cornwall. 'Greissen,' a granite without feldspar, is, indeed, the habitat of tin the world over. The oxide, or cassiterite, is the tin ore of commerce; 'wood-tin' is the same mineral, and owes its name to the annular arrangement of its particles. Stannite, or the sulphide of tin, is merely a cabinet curiosity. The accessory minerals are quartz, calcite (or 'spar'), fluorspar, barite (locally termed 'peach'), and tourmaline; and of the metallic minerals, mispickel, pyrite, and wolfram, are the most common. Tantalite occurs in the Breage district.

The general strike of the veins is east and west, although, as a matter of fact, they vary little short of the quadrant from north to east. The popular opinion is that what is termed a 'true tin lode' must have a strike approximating east and west. This is often the case, but there are others. Usually the dip is steep, although there are exceptions—as on the great flat lode, typified by the Wheal Grenville mine, and in the St. Agnes district by Wheal Kitty.

The orebodies are both impregnations and molecular replacements, fluoric acid being deemed the dissolving medium—on account of the presence of fluorine minerals, such as fluorspar. The stanniferous contents are supposed to have been deposited from thermal solutions coursing through the small and central fissures, and presumably gathered from the sparse occurrence of tin in the igneous rock. Cross-courses, or displacements by dikes of diabase and allied eruptives—locally termed 'greenstones' and 'elvan'—are common. The great cross-course east of the Dolcoath sett is a typical example, it has served as an impenetrable barrier for water and has exerted an influence on the enrichment of the deposit.

The St. Agnes mines, notably Wheal Kitty, contain beautiful examples of reversed faults; these veins occur in the slates or 'killas,' with a decidedly flat dip.

The tin contents of the workable deposits vary; at Dolcoath, the leading mine of the county, the yield on the lowest level is over 1¼ cwt. tin per ton, that is, over 6% black tin. This is unusual; probably 2½% is a fair average of the tinstone stamped during the last few years; but this, again, depends on the price of the metal. The higher the metal, the lower value the ground that can be profitably worked.

Tin is usually returned in percentage of black tin, that is, the 'concentrate,' which assays from 60 to 70% metallic tin for the highest grades, and, in consequence, must be very cleanly dressed. Secondary grades are considerably lower. The returns in pounds sterling per fathom is happily giving place to more intelligible forms—such as pounds per ton, or the percentage, of cassiterite. The assay of tin is roughly ascertained by the vanning shovel and gives a working result, rather than the absolute contents of the sample—the return always being in black tin per ton of ore, or per fathom.

Clitters Limited mines have been largely instrumental in determining the practicability of the successful dressing of complex ores, containing, in addition to tin, considerable quantities of arsenic, in the form of mispickel and other impurities. The mineral contents per ton (exclusive of arsenic) are 21.28 lb., a considerable portion of the ore milled coming from the old dumps—left from the days when complex ores were practically unworkable. The high prices of black tin, at about £100 per ton, with the sale of the other products, has permitted remunerative returns. There are numerous properties in the eastern and middle part of Cornwall with like ores, hence the importance of this successful experiment. The metals derived from the ore are said to be worth 16s. 11d. per ton, with a working cost of 13s. 8d., leaving a profit of 3s. 3d. per ton treated. Minerals of like specific gravity cannot be separated from each other efficiently by any form of water concentration; after roasting, however, these equal-weight ore particles assume varying properties electrically, that is, they become either positive or negative, or good or bad conductors. Good conductors are

pyrite, chalcopyrite, marcasite, pyrrhotite, hematite, magnetite, siderite, cassiterite, wolframite, rhodonite, garnet, galenite, and graphite. Bad conductors are quartz, dolomite, calcite, barite, apatite, sphalerite, smithsonite. By magnetic separators, therefore, it becomes possible to separate minerals of equal specific gravity and having opposite electrical properties, as galena and blende, or, of like property, as cassiterite and wolframite. Advantage has been taken of electrical separators, such as the Wetherill, in these modern concentrating plants.

The black tin is sold either privately or by auction to local smelters, which reduce it when mixed with 'culm' (small anthracite), lime being added as a flux, if excess of silica be present. The furnaces are reverberatories, coal-fired. It is then run into ingots as pig tin, and subsequently, remelted and refined. 'Poling' with wet green apple-logs is a feature of refining and is effective in bringing dross to the surface. Cornish refined tin is the purest in the market. Straits tin is, however, largely purchased and, presumably, mixed with home tin, thus grading the quality of the former.

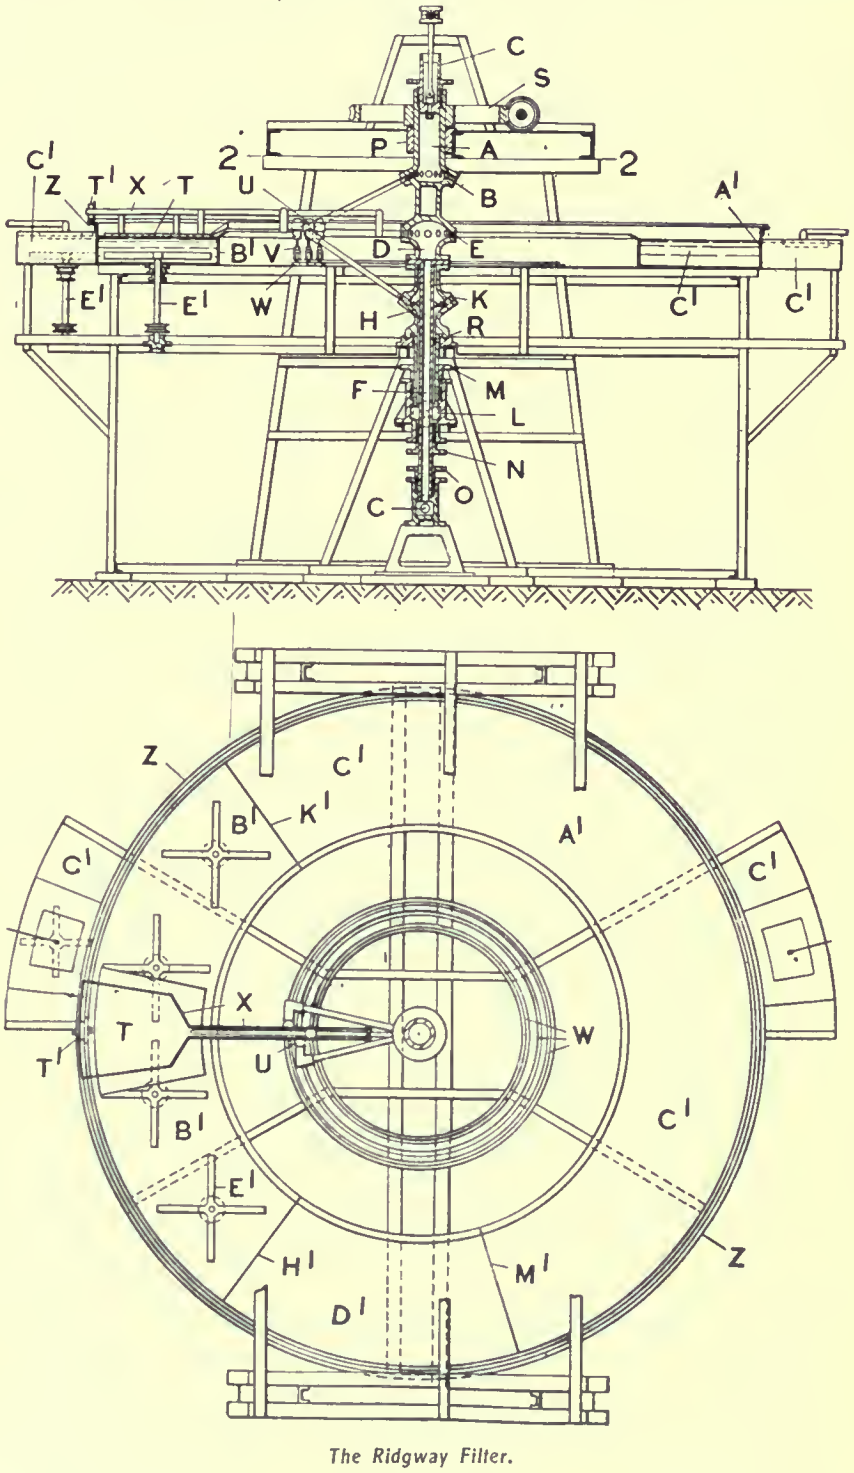
THE periodicals devoted to the literature of science have proved to be a most useful and at the same time a most interesting aid for all kinds of work in any way connected with science. In our age, which is turning from a narrow specialism to a broader conception of all scientific problems, the use of this aid will become more and more general, and what, up to the present, has been a luxury for a few, will become a necessity for everybody. As the giant of Science retains the use of his strength only through contact with mother earth, and becomes powerless when lifted into the airy regions of pure speculation, so, in the same way, the knowledge of science retains its true life in the mind of the individual only when it is continuously stimulated by immediate contact with the works of its great masters.—*W. Ostwald.*

IN the electrical industries aluminum could be used as a substitute for copper for some purposes in large quantities. But the demand for aluminum has also been greater than the supply, and the sole producer is said to be many months behind in his orders. The price of aluminum has, therefore, naturally been high; the parallelism between the price fluctuations of copper and aluminum is, of course, is no sense incidental. While it is estimated that the output of aluminum was 30% larger in 1906 than in 1905, a very much larger increase is expected for 1907, since the Pittsburg Reduction Co. is making the strongest efforts to fortify its already very strong position during the remaining two years for which it is protected in the monopoly by the Bradley patent.

The Ridgway Filter.

*This invention is designed particularly for treating slime containing gold in solution. A trial machine was built on the Great Boulder mine, at Kalgoorlie, and has been constantly in operation since January, 1906.

This machine consists of 12 flat cast-iron filtering frames (T), which are in the form of sectors of a circle.



The Ridgway Filter.

The frames are corrugated on their under surfaces, and to these corrugated surfaces screens are attached; ordinary filter-cloth is fixed over the screens. The frames are suspended horizontally from radially arranged levers (X), the inner ends of which are connected to a vertical centre column or spindle, provided with internal compartments. Each filtering frame is also connected by three radial pipes and rubber hoses to different compartments in the central column.

The outer edges of the filtering frames form the periphery of a circle 12 ft. in diameter; immediately outside

* From the *Monthly Journal* of the Chamber of Mines of Western Australia. November, 1906.

this periphery is placed a circular rail track (Z), and to the outer end of the levers (X) are attached wheels or rollers (T 1), of 4 in. diam. The wheels support the levers and run on the circular track (Z), which is carried on the outer edge of an annular trough under the filtering frames. The trough is divided into three compartments — one for slime-pulp, one for wash-solution, and one (without a bottom) for residue discharge. The general level of the track (Z) is such that the frame has its lower surface only immersed; the track, however, has elevated portions so arranged that when the central column and frames are rotated, the wheels, in running up the elevation, lift the filtering frames out of one compartment, and, on descending, lower the frame into another.

The lower part of the central column has two passages, into which the solutions are drawn, by a vacuum, through the radial pipes that connect with the filtering frames — the vacuum being produced by a pump connected with the openings (G 1 and L) near the bottom of the column — air-tight connections between rotating and stationary parts being secured by means of glands and stuffing-boxes.

A nest of three valves (U) is placed in the pipes between the column and each filter-frame; each of the three valves is automatically operated while the machine is in motion by small rollers (V) passing over elevations on one or other of the three tracks shown at (W); the gold solution is thus delivered into one compartment of the central column through one of the valves, and the wash solution into the other compartment through another valve, thus providing for the two solutions being kept separate. A third pipe connects the third valve (at U) with the top or compressed air section of the column (at B), and while the frame is passing over the discharge chute this valve is automatically opened by its roller and a puff of compressed air enters the filter-frame and displaces the residue adhering to the cloth; the residue falls through the discharge chute (D 1) into a dump-truck. Each frame acts independently, having its own roller, set of valves, and connections with the central column; and each frame and its adjuncts form a complete self-acting unit. The accompanying drawing shows a single-plunger air-compressor (at C), self-contained and driven by the machine itself; the compressed air can, in many instances, be supplied conveniently from other sources.

The machine requires about ½ h.p., and is driven (in the direction of the hands of a watch) with a 6-in. belt on a 42-in. pulley keyed to the top of the central column (at S), and makes one revolution per minute. The vacuum is on the filter-plate the whole time it is immersed — whether in the pulp or in the solution wash. Each filter-frame is 13 seconds in the pulp (from B 1 to B 1), seven seconds on the elevated portion while passing from the slime to the wash compartment, 30 seconds passing through the wash (C 1 to C 1), seven seconds lifting and drying, and three seconds blowing residue off (at D 1). During the period in which the frame is passing from the pulp to the wash, the vacuum is on for one second only while the frame is rising, and one second only while it is descending into the wash, thus giving the pulp adhering to the underside of the frame an air-leaching of two seconds' duration. This period of leaching may be varied to suit the particular nature of the slime under treatment or the thickness to which it has formed on the cloth, which is usually about ⅜ of an inch. The supply of pulp, wash-solution, or water into the annular troughs, (B 1 and C 1), is regulated by means of float-valves in the receiving compartments (G 1 and G 1); the pulp is kept from settling by the revolution of small agitators driven by a rope passing round pulleys attached to their spindles, which project through glands and stuffing-boxes in the bottom of the receiver (at E 1 and E 1), etc. By means of the float-valve in the pulp-receiver (G 1), the pulp supply is taken automatically from the pipes through which the Dehne presses are charged; thus, in order to compare the efficiency of extraction by the machine with that of the presses, a portion of the general pulp is taken as each Dehne press is filled.

From 0.8 to one ton of wash is used per ton of dry slime, and the residues contain from 28 to 33% moisture, and from nil to a trace of KCN and soluble gold. The tonnage treated in 24 hours and percentage of moisture contained in the residues vary according to the variations in the pulp. With clean quartz slime of a consistency of from 42 to 44% solid, and a fineness of about 92% through a screen having 200 holes per linear inch, and a vacuum of 20 in., this machine will treat 50 tons of dry slime per 24 hours, leaving a residual moisture of 30 per cent.

On a clay slime the output will decrease to 25 tons per 24 hours, and the residual moisture will increase 35%. A trial was made on the old battery slime; the original assay value was 7 dwt., the gold in residue 18 gr., moisture in residue 35%, soluble gold in residue nil; this was treated at the rate of 25 tons per 24 hours.

Each frame has four square feet of filtering area and about 0.8 square yard of cloth is used to cover each frame. The life of a cloth on slime from the Great Boulder roasted ore is about 14 days, or 700 tons of slime for 9.6 sq. yd. of cloth.

The vacuum pump has a piston sweep of 80 cu. ft. per min., and, with a 20-in. vacuum, requires 3½ h.p. The machine itself, without the self-acting air-compressor, requires about ½ h.p., and allowing 1 h.p. for the agitators in the pulp-trough and pulp-receiver, and for friction in the counter-shaft, a total of 5 h.p. is required to drive the equipment described.

As the machine is absolutely automatic in its entire operation, no additional labor is employed in running it. Taking into consideration that this is the first machine made of this pattern, the repairs and renewals have not been abnormal.

The working costs during the last three months have been:

	Pence.	
Filter-cloth	0.3	per ton
Horse-power	2.4	"
Repairs and renewals	1.0	"
Total	3.7	"

It has been impossible to segregate the labor cost on this machine (other than those included in repairs and renewals), as during the whole run any slight attention necessary, other than greasing, has been performed by the shift-boss on duty.

The method of operating the machine is as follows: The agitators in the pulp compartment of the annular trough are first set in motion, being driven independently of the machine; the pulp-compartment is filled to normal level with agitated pulp, and the wash-compartment with wash-solution. The vacuum-pump is started, and the machine is set in motion by applying a tension-pulley to the belt on the pulley attached to the top of the centre column of the machine, thus rotating the centre column, which imparts the motion to the filter-frames by the pipes and levers, causing the rollers (T 1) supporting the outer end of the levers from which the filter-frames are suspended, to travel on their track (Z). As the action of all the frames and their connections is similar, one only need be described. Assuming that a frame has just passed over the discharge chute and is on the elevated portion of the track, it then descends an incline on the track to the normal level, and the cloth on the underside of the frame is immersed in the pulp; at the same

time, the gold solution valve (at U) is opened by a roller (at V) running up an incline on its track (W), and similarly to the action of the elevating rollers (at T 1) on the track (at Z), thus opening direct connection between the filter-frame and the vacuum which is maintained in the centre column; the vacuum draws the liquid through the cloth and leaves the solids adhering to it. The roller (T 1) on the outer end of the lever, while continuing on the level track, keeps the cloth submerged till another incline is reached, up which it then ascends, lifting the frame out of the pulp-trough; on descending the incline again to normal level, the frame is lowered into the wash-solution. When the frame ascended from the pulp, the gold-solution valve closed, and as it descended into the wash-solution the wash-valve opened, causing the vacuum to draw the wash though the adhering pulp, which is usually about ⅜ of an inch thick. The frame continues in the wash-trough during the travel of half the circle, and is then raised by similar means to those already described, but the wash-valve is not closed till the discharge chute is reached, thus allowing the vacuum to remove, by air-drying, some of the moisture from the cake of slime formed on the underside of the cloth. When the discharge chute is reached, the wash-valve closes, and the air-valve in connection with the upper portion (B) of central column is opened, admitting a puff of compressed air, which dislodges the cake from the cloth and precipitates it into the discharge chute (D 1), under which a dump truck is placed to receive residues. The compressed air required at the time of the discharge can be supplied in any usual way or by the self-contained arrangement shown in the drawing at C.

Enlarging the Anaconda Smelter.

During the year 1906 improvements have been made at this plant for which half a million dollars had been set aside. Now, nearly completed, they include the following additions to the plant:

At the beginning of the year there were two 51-ft. furnaces, and three 15-ft. furnaces in the blast-furnace building of the plant. These three have been thrown into one, making a furnace 87 ft. long, and based upon the 51-ft. furnace, with a capacity of at least 3,000 tons of charge daily. In this way the blast-furnace capacity has been raised 1,740 tons daily.

Eight McDougall roasting-furnaces in two rows have been installed in the roaster building, which should furnish upward of 300 tons of roasted ore. This is taken care of by one 116-ft. reverberatory furnace, with an output of 60 tons of 40% copper matte.

The Flint Creek power station has been re-modeled for the purpose of furnishing power to the concentrating-mill, where it drives motors that have been substituted for the steam-engines heretofore in use.

To have an assured and abundant supply of water for concentrating, the Silver Lake pumping station has been re-modeled, and a further supply is obtainable from Hoefner's pumping station at the race-track, the water being pumped in time of low water across from the old flume to the new one.

To dispose of some 230 tons of matte estimated as coming from the 2,040 tons of additional ore, two additional bays have been built to the last end of the converter building, and one of the two converter stands needed is being placed. This space also gives room for another slag-casting machine.

MANGANESE STEEL is an alloy of iron and manganese, incidentally, and probably unavoidably, containing a considerable proportion of carbon.

The Art of Exaggeration.

In these days one hears of $7,000,000 gold shipments, mountains of copper ore, veins of gold that rib creation, and other mining stories that find ready space in the daily press. Here is Mark Twain's reply, written many years ago, to one such yarn:

"I have just seen your dispatch from San Francisco in Saturday evening's *Post*," wrote Mark Twain on the subject of rich gold deposits at Calistoga springs, and about the proprietor's having extracted 1,600 oz. of gold of the utmost fineness from two barrels of water during the past fortnight, by a process known only to himself.

"This will surprise many of your readers, but it does not surprise me, for I once owned these springs myself. What does surprise me, however, is the falling off in richness of the water. In my time the yield was a dollar a dipperful. I am not saying this to injure the property in case a sale is contemplated. I am saying it in the interest of history. It may be that the hotel proprietor's process is an inferior one. Yes, that may be the fault. Mine was to take my uncle (I had an extra one at that time on account of his parents dying and leaving him on my hands) and fill him up and let him stand fifteen minutes, to give the water a chance to settle. Well, then I inserted him in an exhaust receiver, which had the effect of sucking the gold out through his pores. I have taken more than $11,000 out of that old man in less than a day and a half.

I should have held on to those springs, but for the badness of the roads and the difficulty of getting the gold to market. I consider that the gold-yielding water is in many respects remarkable, and yet no more remarkable than the gold-bearing air of Catgut cañon up there toward the head of the auriferous range. This air, or this wind—for it is a kind of a trade wind which blows steadily down through 600 miles of the richest quartz croppings during an hour and a quarter every day except Sundays—is heavily charged with exquisitely fine, impalpable gold.

Nothing precipitates and solidifies this gold so readily as contact with human flesh heated by passion. The time that William Abrahams was disappointed in love he used to sit out doors when the wind was blowing, and come in again and begin to sigh, and I would extract over a dollar and a half out of every sigh. He sighed right along, and the time that John Harbinson and Aleck Norton quarreled about Harbinson's dog, they stood there swearing at each other; and they knew how, and what they didn't know about swearing they couldn't learn from you and me, not by a good deal; and at the end of every three or four minutes they had to stop and declare a dividend. If they didn't their jaws would clog up so they couldn't get big nine-syllable ones out at all, and when the wind was done blowing they cleared up just a little over $1,600 apiece. I know these facts to be absolutely true, because I got them from a man whose mother I knew personally.

I do not suppose a person could buy the water privileges at Calistoga now at any price, but several good locations along the course of the Catgut cañon gold-bearing trade winds are for sale. They are going to be stocked for the New York market. They will sell, too, people will swarm for them as thick as Hancock veterans in the South."

OLD KING ARTHUR, who, in his wise, practical views of life, seems to resemble our Benjamin Franklin, gave the maxim: "Eight hours for work, eight hours for rest, and eight hours for play." Proper industrial training will bring about this consummation by increasing the efficiency of the workman.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

Under a deed conveying mineral rights which provided that the grantee should have free access to the lands from any direction by roads and other pass-ways or means of exit and entrance it was decided by the Court that the grantee would have the right to construct such roads, pass-ways or means of exit, or entrance as might be necessary to get out the mineral, having due regard to the interests of the owner of the soil, and not inflicting upon him any unnecessary damages. It was claimed in this case that the provision in the deed as to roads and other pass-ways or means of exit or entrance did not give the grantee the right to construct a tramway. The Court decided that the tramway was necessary to facilitate the increased output from the mine, and that such a tramway was but an improved road or passway; that it took less space than a road would take, and would be less injurious to the land than a road, and that the grantee under the terms of the deed had the right to make and use the tramway.

Duncan *v.* American &c. Asphalt Co., (Ky.) 97 S. W. 392.

In an action to determine adverse interests in real property, the defendant based his claim to such property solely on a lode mining location. The Court found that the defendant was and had been since 1883 the owner and in possession of a specified portion of the disputed premises. It was held that this was an implied finding, that such mineral location was actually made in that year; that the land was mineral in its character; that the claim was properly monumented; that the annual work was done thereon as provided by law and the mining regulations, and that the claim was not abandoned.

Southern Cal. R. Co. *v.* O'Donnell, (Cal.) 85 Pac. 932.

It is the duty of the owner of a mine to furnish the miners a safe place in which to work; and where a miner was ignorant of the danger of the place in which he worked, and could not by ordinary care have discovered such danger, it was said to be the duty of the employer to inform him of the situation; and in the absence of an official of a higher position this duty devolved upon the foreman, under whom the miner was working. In States where the statute provides for the appointment of a mine boss, it is his duty to see that the place where the miner works is reasonably safe, and such a mine boss is not a fellow servant of the miner.

Low Moor Iron Co. *v.* La Bianca (Va.), 55 S. E. 532.

The rule requiring the owner of a mine to use reasonable diligence to furnish a reasonably safe place for the miners to work has no application to the miners or persons whose duty it is to make dangerous places safe. Such persons neeessarily assume the additional hazard of the particular employment. By this is meant that the statute does not require that the mine examiner shall aecompany the rockmen and personally direct them in removing dangerous conditions from the mine.

Kellyville Coal Co. *v.* Bruzas (Ill.), 79 N. E. 309.

Where the location was eross-wise of a vein which ran in a northerly and southerly direction, within a mining claim, and the side lines were really end lines, considering the direction of the lode on the surface, it was decided that the rights of the locators were restricted to the area, within the side lines 300 ft. on each side of such a vein or lode.

Southern Cal. R. Co. *v.* O'Donnell, (Cal. App.) 85 Pac. 932.

It has been decided that the rights of one entering upon the public domain and locating and working a mineral claim are of as high order as those of a settler, each of whom is in possession under rights initiated which may by the observation of precedent conditions ripen into the right to a final patent.

Southern Cal. R. Co. *v.* O'Donnell, (Cal. App.), 85 Pac. 932.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The rock from Glendale, Oregon, sent by J. W. S., is: Diabase.

Platy Barite stained with Limonite has been sent by J. S., of Bearmouth, Montana.

The specimen of radium ore sent by W. H. W., of Amalie, Kern county, Cal., has not been received.

Two rock samples from Wonder, Nev., marked H. G. G., are: No. 1, Diorite; No. 2, Quartz with black inclusions.

The specimens from Pocatello, Idaho, marked J. H. M., are: No. 1, Quartz and Limestone; No. 2, cherty Limestone.

The material sent by V. E. M., of Glendale, Ariz., is: No. 1, black Tourmaline; No. 2, Quartz and Pyrite; No. 3, Hornstone.

The blue mineral from Carson City, marked H. McC., appears optically and chemically to be Dumortierite, an alumina silicate sometimes containing boron.

Rocks from Los Angeles marked H. H., are No. 1 and 2, biotite Granite; No. 3, basic segregation from biotite Granite; No. 4, Pyrrhotite; No. 5, Quartz and Chalcopyrite.

The rocks from Tinemaha, Inyo county, Cal., marked A. C., are: No. 1, Diorite; No. 2, Sandstone; No. 3, decomposed granitic rock; No. 4, chlorite Schist; No. 5, similar to No. 3; No. 6, clayey material from the same kind of rock; No. 7, earthy Limonite and Jasper; No. 8, Jasper; No. 9, Quartz with oxidized Pyrite.

COMPRESSED AIR differs from electricity, especially in the fact that electrical friction losses cannot be regained, while corresponding losses with compressed air may be eliminated. The moderate fall in pressure in the air due to friction augments a loss of transmission. If the air were at 80-lb. gauge or 95 lb. absolute upon entering the pipe, and 70-lb. gauge or 85 lb. absolute at the other end, there would be a loss of a trifle more than 10% in absolute pressure, but at the same time there would be an increase of volume of 11% to compensate for this loss of pressure, and the loss of available power would be less than three per cent.

THE height of tides varies greatly in different localities. In the open Pacific it is only two or three feet. In the North Sea interference of two tidal waves, one from the north of Scotland, the other through the English channel, minimizes the effect. In nearly enclosed seas, like the Mediterranean, they are only a few inches high. The Channel Islands, to the south of England, have tides some 35 ft. high, while in narrow reaches such as the Bay of Fundy, into which large masses of water are driven by their momentum, the tide may rise 70 ft. or more.

WROUGHT IRON is graded as to the three factors: Tensile strength, reduction of area, and elongation. The average tensile strength is about 50,000 pounds per square inch, the reduction of area before breaking in the testing machine varies from 25 to 55%, and the elongation from 30 to 10 per cent.

The Big Shafts of Guanajuato.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

In my last article I took the reader to the Rayas mine. Just as I was about to describe the view, the exigencies of space in our issue of December 22 compelled me to stop. I give it now, as it appeared from the *mirador* or stone balcony on the morning of November 2, 1905.

In the distance to the left, the bold ridge of La Bufa, a scarp of rhyolite tuff, stood silhouetted against the clear blue. Under the overhanging brows of these cliffs and protected from the weather, there are figures of heroic size painted on the rock; they represent a red devil and his retinue tempting the Christ. In the cavern adjoining these are several paintings of St. Ignacio and the Virgin, done in color with as much skill as the similar work to be seen in the churches. This mountain top—from which may be seen Guanajuato, Silao, Leon, and the wide expanse of the rich Bajio—was supposed to suggest that from which El Salvador was shown the kingdom of this world and their glory, in the great temptation. Lower down, near the talus slope, the other temptations are depicted in a crude way. It is not said that the riches of the Veta Madre were offered; they have tempted many men to their undoing during the last two hundred years.

On the rounded foothills that extend from the base of La Bufa begins the residence portion of Guanajuato—it is called La Presa, because of its dominant feature, a big dam with an encircling park. Seen from a distance, there is a gleam of pink walls among cedars and the tops of some church towers; then the crest of a ridge intervenes. At the foot of this and in the cañada below the Rayas, there is a cluster of brown ruins, La Duran, the oldest *hacienda de beneficio* in Guanajuato, and contemporaneous with the discovery of the *patio* process, in 1557. A hundred yards below it, the bed of the stream is crossed by the slender line of an aqueduct, that now serves to carry the pipe-line which brings the water-supply of the town. The six pillars are capped by a series of broad keystones, that do duty as arches. This is a characteristic type of Mexican architecture.* Below the aqueduct, the cañada turns to the right and becomes fringed by Peruvian pepper trees, and beyond them is the big hollow in which the town of Guanajuato lies huddled—a multitudinous complex of walls—pink, yellow, and white—with red Moorish campaniles. The narrow river-bed is marked by a congestion of brown walls; on the onlooking slopes there is a decrease in this density of buildings and an increase of verdure, until the top of the ridges are reached, where there are no dwellings, but only the dark red earth of the cornfields, defined by hedges of organ cactus. Surrounding the town and overlooking it, are golden brown hills, with contours deeply eroded and steep ravines (*barrancas*), the culminating point being the cone of Cubilete. The broken skyline is carved in diabase, and the nearer slopes are eroded in the conglomerate that lies on the flanks of the main ridge.

A Glimpse of Guanajuato Between the Organ Cactus.

In front, beyond the huddled habitations of man and the brown hills crossed by the traveling shadows of clouds that fleck the vivid blue of the sky, stretches the purple interval that marks the Bajio, a great valley along which runs the Mexican Central—a most unromantic railroad, with slow trains, sloppy Chinese cooking, and a most distressing service. Beyond it, like the good things promised on the other side of this vale of tears, is the blue line of the Cordilleras, throbbing with soft enchantment and pulsating with the romance of mining that shall not die.

When luncheon was over we left the *mirador*, and in doing so passed through the remains of a pretty garden; it seemed strange to see the old-fashioned gilly flower, rose bushes, and violets among these mine buildings. They had a story to tell of the Englishmen who planted them. There was a time, from 1821 to 1850, when English capital irrigated the mining camps of Mexico,

*The 'flat arch' is held by some to be the oldest and simplest expedient for supporting a structure; it is supposed to have originated from the big stone placed over a doorway in the days before the idea of the true arch was developed. Other engineers, for instance, Mr. Carlos Van Law, are of the opinion that the flat arch was a development from the true arch, and that, in form and principle, it is the real origin of our modern 'invention' of fire-proof floor construction with its so-called arch-tiles.

and among them Guanajuato. Owing to the costly methods of operation, the attempt to employ only the comparatively expensive imported white labor, and the lack of experience in treating the silicious silver ores, these early efforts were generally unprofitable, although with their characteristic dogged determination, the English companies continued to operate the mines, with steadily diminishing intensity, for many years. While active work on any important mine ceased fifty years ago, they held on to the San Cayetano until a few months ago, when that property was transferred by the United Mexican Mines Association, Ltd., organized in 1814, to a new American company. Between the English period, already defined, and the present American dispensation, there was a good deal of work done under Mexican companies, although these lacked the enterprise of the heroic days at the very beginning of the nineteenth century.

The four great shafts on the Veta Madre are the Rayas, the Cata, and the two pits of the Valenciana, namely, those of San José and Guadalupe.

The Rayas is octagonal and 38 ft. diam., with a depth of 1,400 ft. Among the old machinery to be seen near-by is a Cornish hoisting engine of 1835 built by Harvey & Co., at Hayle, Cornwall. Alongside are two Lancashire boilers. In another building is a first-motion hoist built by the Union Iron Works, of San Francisco, in 1866; it is one of the best of the old style, with jaw brake and flat wire-ropes. The head-frame is built with timber struts footed in cemented masonry. This was erected in 1887, when the Rayas mine was unwatered. But there is a suggestion of methods used long before even this old machinery was set to work; the sites of the horse-whims used by the Mexicans is marked by a tablet inscribed to the patron saint of each operator. One, for instance, reads "San Francisco. Nov. 1, 1820."

The Cata shaft is 280 metres, or nearly 1,000 ft., deep and 20 ft. wide. At the collar, and for 50 ft. down, it is octagonal, with sides of masonry. I went down in a cage running on wire-rope guides, which gave one a feeling of detachment, for in places, below the portion that is lined with masonry, the shaft is 30 to 40 ft. wide. A native boy held a torch to illuminate the distant sides of the shaft. The torch used in the mines is worth describing: It is called a *mecha* and consists of 40 native candles, made of tallow and yarn, which are pounded into a mass and wrapped in a cloth with wood splints to stiffen it. Outside of this is a wrapping of *riata* or twine, obtained from the *maguey* plant. The torch is two feet long and 2½ in. thick; it is wetted outside, so that the tallow will congeal as it drips. By the light of it, when we reached the bottom of the shaft, we saw the Aldrich quintuplex pump, made by the Allentown Rolling Mills, Pennsylvania. It consists of a battery of five vertical plungers, all the five cranks inside, with two post-bearings outside. This pump is said to be doing good work, lifting 300 gal. per min. 880 ft. high, to the drainage adit.

The San José shaft was also known as the *tiro general* or general shaft of the Valenciana; it has been mentioned already in recounting the early history of Guanajuato. It is an impressive hole. There is none like it. It is octagonal, 33 ft. in diameter and lined with masonry for 100 ft. The bottom is at 525 metres or 1,625 ft. Water-level stood at 198 m. or 600 ft. at the time of my visit. This is the shaft of which it was truly said—among others, so I was informed, by Robert Bunsen at Leadville in 1881—that a man can read his paper at the bottom by the light of the sun, because here in the tropics during the summer solstice the sun for two weeks is vertically overhead. Early in July the mist caused by the sun's heat striking directly on the water at the bottom of the shaft causes a beautiful rainbow every day at noon. This is the shaft also of which William Jennings Bryan—who visited Mexico after his first silver campaign and was royally entertained—said, that he had never before seen a hole big enough and deep enough wherein to bury the gold standard. But he said nothing at all about the shallowness of the oratory of the river Platte! However deep the shaft may be, it will be filled up some day unless tourists are forbidden a near approach. From time out of mind it has been deemed great sport to throw stones down this vast pit and listen to the reverberations. I offered my tribute to the Tiro General. First one hears the sound of rushing wind—the echo of the passage of the stone through the air; then there comes a roar as it strikes the side of the shaft and this is followed by a crash as it hits the water. (In the light of later events I can tell my friends at Guanajuato that these sounds resemble the oncoming of an earthquake, to anyone living near the actual line of faulting.)

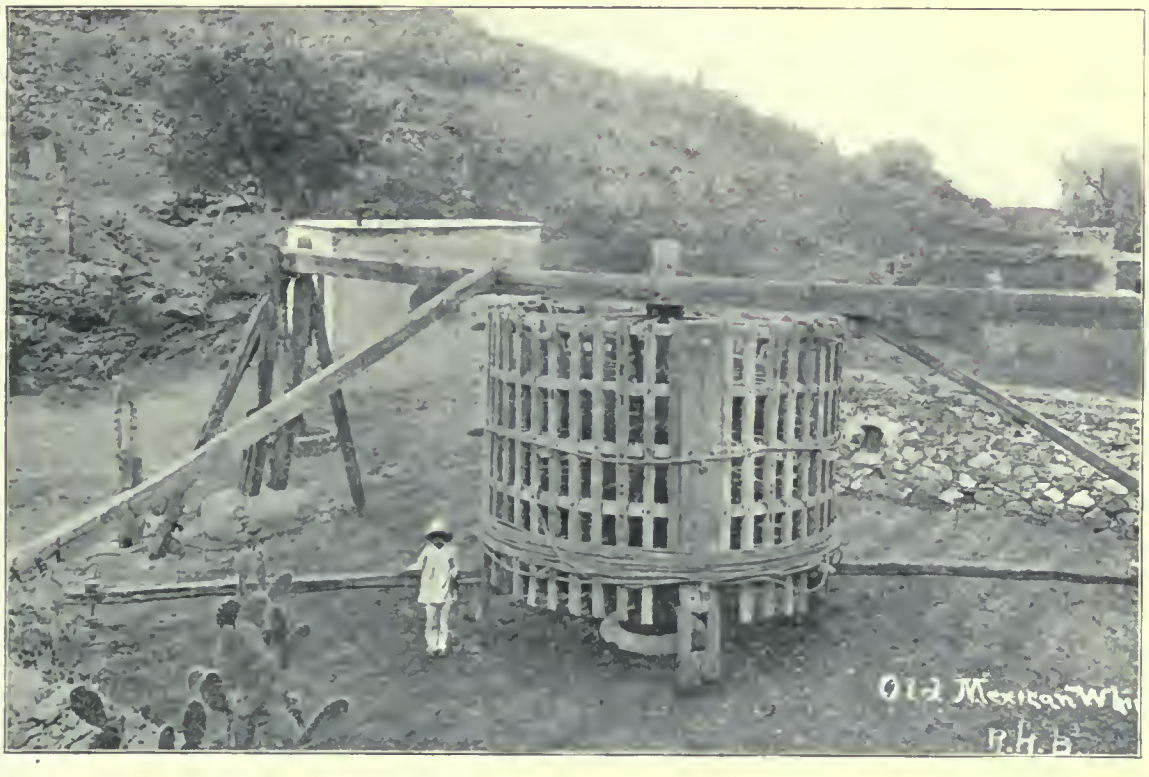
The shaft is octagonal, this shape being due to the method of hoisting prevailing at the time it was sunk. Around it, at a radius of 150 ft., can still be seen the ruined gables of the eight houses, each of which contained a *malacate* or horse-whim. A *malacate* is said by the Mexicans to be operated by *fuerza de sangre* or force of blood, as compared to the *fuerza de vapor* or steam-hoist. The typical *malacate* employed in this work was usually a vertical drum of oak or *mesquite*, from 12 to 16 ft. diam. and 12 to 14 ft. high, with a wooden central axis supported on iron gudgeons, top and bottom. The lower end of this drum was about three feet off the ground and to it were fixed four heavy *mesquite* sweeps of 15 ft. radius. To the end of each sweep were harnessed four horses, in crude rawhide harness, driven by a boy (seated on each sweep), at a gallop around the circle. Originally a hemp rope—later, a steel cable—was wound eight or ten turns around the drum, both ends depending in the shaft and hoisting in balance. The trip complete, the horses were reversed on the sweep and the return trip commenced. As, with the depths worked, the empty bucket, plus rope, considerably overbalanced the load when the latter neared the surface, the driving boys usually had to hop down from their perch toward the end of each trip and restrain the motion of the drum by holding back while the horses were turned out to one side and disconnected, all without stopping the hoisting. There was no brake on any of these old *malacates;* when it was desired to hold them at any given point, an attachment was made to the nearest fixed timber.

Rawhide buckets, made by sewing together two bulls' hides, were used exclusively. In these, both ore and water were hoisted, and the experience of American engineers has proved that for taking water out of shafts in sinking, the rawhide is better than anything else, being lighter and easier to handle in proportion to the quantity of water raised than any other form of bailer.

Over the shaft stands the shaky head-frame built in 1872 during the unwatering of the mine by the engineers of the Mexican company. They started with four winches, not over 20 h.p. apiece, and fooled along for nine years, finally getting the water out; then, in 1881, they purchased a good Fraser & Chalmers double-drum double-cylinder winding engine of 120 h.p. Mr. Dwight Furness, who was in our party, told me that when he visited the mine in 1888, the yard was full of women engaged in sorting ore. They sent 300 tons of clean ore to the mills, the remainder being shipped to Germany. These operations stopped in 1892, and the water has been rising in the shaft ever since. I saw some of the little hoists used in 1872; they had teeth-gearing made of mortised wood; they came from Manchester and were brought on ox-carts from Vera Cruz, a distance of fully 500 miles.

The unwatering of the shaft must have been a wonderful spectacle; the story of it is told in the old company's records. When they began, there were four steam-hoists raising as many iron buckets restrained by wire guides. The water being high in the shaft, it was not possible to anchor the guides to the bottom, so they were attached to a big wooden float, which was weighted until it sank. Then the upper ends of the guide-ropes were run over sheaves, in order that they might be paid out as the water was lowered. So long as only one hoist was running, all went fiuely; but when all four got to work, the apparatus, that is, the float, guide-ropes, and *toneles* (bailing-buckets) commenced to twist until the whole lot of them were completely wound up in an utterly hopeless tangle. The bailing operations had removed the water unequally over the area of the shaft, and this had created a vortex that caused the float to move around, twisting the 16 ropes used as guides and the eight more employed in balance-hoisting, until with the cables and guides, completely interrupting the maneuvres. Many times we four engineers repeated the trial through a whole day, and the following day with only three (since he who recites this fell ill), without obtaining any favorable result. The three companions came to the bedside of the patient completely disheartened and sad, as was to be expected, but at the same instant the same exclamation burst from the mouths of all, the very syllables falling together, without anyone of the four being able to say, 'I was the first to speak'; we shouted, '*We will secure the fixity of the frame with diagonal props resting against the walls of the shaft*'! This common idea was the equivalent of the *Eureka!* of the Greeks. It raised the patient from his bed, re-established happiness and, when put in operation, it gave the much desired result. The ninth day of June, 1873, the unwatering was inaugurated with great solemnity."

What a scene it must have been; the courtyard fairly buzzing with the noise of the little hoists, the shouts of the



A Mexican Malacate or Horse-whim.

rapidly increasing gyrations, the float became the base of a tangle that baffled description and made the engineers hysterical.

After the unwatering was completed, in 1881, Miguel Rul made a speech* before the Guanajuato Society of Engineers, and in that speech he dwelt upon their early troubles. The speech is on record. He describes the cylindrical sheet-iron bailers, made of galvanized sheets of No. 22 iron, with wooden bottoms and rawhide valves; he tells of the various difficulties with the valve mechanism and over-winding, and then he finally comes to the trouble connected with the attachment for the eight wire-guides below the surface of the water in the shaft. I quote his words: "On making the general trial with the four hoisters, after many partial trials which had resulted well, we noticed a phenomenon which disconcerted us. The effect of the different movements on the single timber-frame, to which the guides were attached below water-level, commenced to stir the water and to produce a tumultuous motion of rotation, which finished by resembling a water-spout and winding up bewildered engineers, the imprecations of the workmen, and the tremendous turmoil of the water in the big shaft as the guide-ropes twisted into a hopeless coil! And then the silence when the whole came to its fatal conclusion, the operations remaining suspended until those three mine captains, gathered around the bed of their invalided comrade, were suddenly inspired with the happy solution of their trouble. The courtyard is empty now, the waters have again invaded the shaft, and the vertical shafts of sunlight once more pierce the gloom above the stagnant pit.

A little farther north is the other great shaft, that of Guadalupe, which is 22 ft. diam., and 325 metres, or 1,072 ft., deep. It has a hexagonal collar built of masonry; through it a great deal of material was hoisted, the dump being the largest in the Veta Madre, containing 350,000 tons.

As a rule the miner does not choose the top of a hill for the site of his shaft; he goes where he can economize on his sinking, without depriving himself of the chance to distribute the waste rock. At Guanajuato the shafts are on knolls, some of which rise to the dignity of hills. The reason for this was the space the Spanish miners wanted

*This speech, before the Guanajuato Society of Engineers, was published in their *Bulletin*, and is dated August 5, 1888.

for their *malacates* or horse-whims. At each shaft there were so many of these that a yard of 100-ft. radius was required. When this had been planned, they would begin to construct a wall just beyond the end of the arms of the *malacate*, the wall being built with the waste (extracted from the shaft), which was then filled into the enclosure until the yard had a level surface. The *haciendas* were rarely near the mine, they were erected in the town, for the sake of safety and convenience. The ore was carried on mules to the *patio* establishments, which were custom mills.

The mines were not worked by their owners but by parties who secured a lease in perpetuity, termed an *avio*, which gave them (the *aviadores*) the right to do what they pleased in the mine, and to make contracts for the disposal of the ore. The *aviadores* charged, as a lien against the mine, all expense of whatever nature they incurred, such as development, operation, taxes, plant—in fact, everything. Against these items they credited the net returns obtained from the sale of ore, but being able to dispose of it wherever they pleased, they built *haciendas* on their own account and then made numerous contracts for the treatment of the ore, and mixed the several grades of it so that the yield could not meet the treatment charges. Then, as the owner never got a *centavo* unless there was a balance to credit, he never received anything. The mine ran up an ever-increasing debt until it amounted to an impossible sum; thus, for example, in the group of mines held by the Guanajuato Mines & Reduction Co., the indebtedness amounted to 6,000,000 *pesos*, most of this sum being entered against four properties—the Rayas, Mellado, Cata, and Valenciana.

The American company bought the *avio* contracts and the debt becomes due to these new owners; the company inherits all the old contracts, including the agreement for ore-treatment; it will never have to pay the old —almost nebulous—owners unless the profits to the mine from sale of ore to reduction works first repay the accumulated interest and then grow into a surplus. All the contracts are based on the old treatment charge, which was: 360 grams silver per ton to be deducted from contents of ore, the balance to be paid for at the rate of 3 *centavos* per gram; and the gold contents up to 6 grams per ton to be paid for at the rate of 30 *centavos* per gram; between 6 and 15 grams the payment to be 45 *centavos*. As the average ore of the best mines contains 350 to 400 grams silver and 3 grams gold, it is pretty obvious that the *aviadores* will not have to make an accounting. Several attempts, naturally, have been made to break these curious Spanish contracts, but in vain. The *aviadores* are the unquestioned owners of the mines today and no court can invalidate their peculiar rights.

The new enterprises at Guanajuato have swallowed the *avios*, and all the big mines have passed out of the hands of the native population. It is a fact that the Mexicans look upon the American operations with scepticism, largely because earlier efforts made by foreigners came to grief. They are inclined to regard with humor the removal of dumps and the working of abandoned mines; in consequence, although the old work was done by their own people, only a few local merchants have any financial interest in the present profitable undertakings.

IF the basin of the Great Lakes continues to tilt toward the west at the present rate of movement, Niagara Falls will be intermittent in 15,000 and dry in 25,000 years. The discharge will then go through the Mississippi river and to the Gulf of Mexico by way of the drainage channel in the vicinity of Chicago, as it did before the glacial retreat.

Effects of Extreme Cold.

E. L. Parsons, an old-time Yukon miner, just returned from the frozen North, told some remarkable stories of happenings at Dawson City, when the thermometer drops many degrees below zero. He said:

"Strange manifestations appear as a result of the extreme cold. A fire in the stove roars and crackles like a great forge, and wood seems to dissolve in the flames like a chunk of ice; the wood is gone and you wonder what became of the heat. At 60° below zero every stovepipe throws out a great white cloud of smoke and vapor, which streams away for fifty or one hundred feet, mingling with the other white-gray mist or haze that remains permanent in the atmosphere, like a fog, whenever such a low temperature is reached. This white-gray fog is not the fog Easterners know, but a frozen mist; every man, woman, child, animal, and even the fire that burns, is throwing out moisture into the air which is immediately turned into a vapor, which remains visibly suspended in the air.

Prospectors in attempting to boil a dish of rice or beans upon a camp fire unprotected from the weather find that the side of the dish which is in the fire will boil while that part exposed to the weather remains cold. Edged tools subjected to this temperature become as hard and as brittle as glass and break as readily under strain. I have seen a safety-valve blowing off steam, with the temperature 60° below zero, with icicles hanging to the valve, having formed from condensation. These icicles did not melt in the outrushing steam, but remained there for many days."

Mr. Parsons told of some instances when a frozen foot, ear, or hand had been thawed by immersion in coal oil for some time—often for several hours. He said: "This is absolutely a safe remedy and one thus escapes the surgeon's knife, as no bad results follow. This is not hearsay, for a man from our camp was found after he had been out all night with the thermometer 50 degrees below zero, and both his hands were frozen to the wrists. He was taken into camp and his hands soaked in coal oil for five hours. All the frost came out and not even a finger tip was lost. The doctors were amazed; as they thought amputation would have to be resorted to." The temperature of the oil should be about the same as that of the living room. Great caution should be exercised during the extremely cold weather not to freeze the lungs, which one will quickly do if he hurries about. Quick and fatal pneumonia can be contracted in a few moments. Many a fine team of horses has been lost in this way up in the Yukon.

One must be careful about touching metals with unprotected hands. It is dangerous to take hold of a doorknob when it is 60° below, or thereabouts, with the unprotected hands, unless you are careful to release your hand instantly, for if you do not it will freeze your inner palm in five seconds, the result being much the same as from touching a red-hot stove. Canned goods undergo great contraction during extreme cold, and take in air; in summer, with a temperature of 90° above zero, the reverse condition prevails, causing leakage and loss.—*Evening Post*, New York.

WULFENITE is the molybdate of lead. It occurs in Arizona in large, flat, transparent crystals of a yellow color. It is commercially valuable when pure, for its molybdenum content.

BELTS should always be run with the smoothest side toward the pulley, as the smooth side gives a greater surface of contact.

A Clever Bit of Engineering.

Written for the MINING AND SCIENTIFIC PRESS
By FRANK ALEY.

The Copper Queen smelter stack grew in height to the extent of sixty feet in less than three hours on December 26, 1906. The manner in which this was done constitutes one of the cleverest feats of construction ever undertaken in the Southwest.

The original stack was 200 ft. high by 25 ft. inside diameter. The company found it necessary to increase the height in order to get a better draft and recover more flue-dust. This undertaking would have been simple enough, except for the fact that a shut-down was not to be considered.

A contract was entered into with the Wisconsin Bridge & Iron Co. to place an extension of 60 ft. on the stack without a shut-down, except for the space of four hours. If the contractor failed to connect in four hours, he was to pay a heavy forfeit for every minute in excess thereof. If he succeeded in completing the work without a shut-down, he was to receive a liberal premium. The work was begun about four months ago. It began with the construction of false work, as shown in the accompanying photographs, constituting a network of timbers, securely bolted throughout. Fifty thousand feet of mine timber was used.

After a multitude of difficulties, arising chiefly from the disinclination of the mechanics to work so far above ground, the false work was brought up to a level with the top of the main stack. At this stage, the plan of construction revealed itself. On this false work, which was considered too weak for the undertaking by the casual observer, the 60-ft. extension was built rapidly, despite delays occasioned by the desertion of workingmen, sulphur smoke, and a score of other obstacles.

The new extension of the stack was constructed with its base in a steel truck, this truck resting on rollers or low wheels, they in turn resting on the heaviest of railroad steel. Round by round, the new section went up until it stood erect and substantial, as shown in Fig. 1. The new extension weighed approximately 60 tons, being composed of 5/16 steel. When completed, it was lightly guyed from the top of the false work and everything was in readiness for the final act. On the morning of December 26, while the people were watching a mile away for the rare event as they would watch for a total eclipse of the sun, the brief space between the new section of stack and a conspicuous timber by the side of it began to widen perceptibly. Wider and wider it grew, until the rim approached the rim of the original stack. The wind was unfavorable and billows of sulphurous smoke enveloped the workmen at times, but the new section never paused. Very soon, a part of the great volume of smoke was seen to be coming through the new section, then fully half of it, then the bulk of it, until the whole was pouring through a 260-ft., instead of a 200-ft., stack and the splendid work was accomplished in three hours. It had been done without shutting down. The engineer was J. F. Jackson, of Houghton, Michigan.

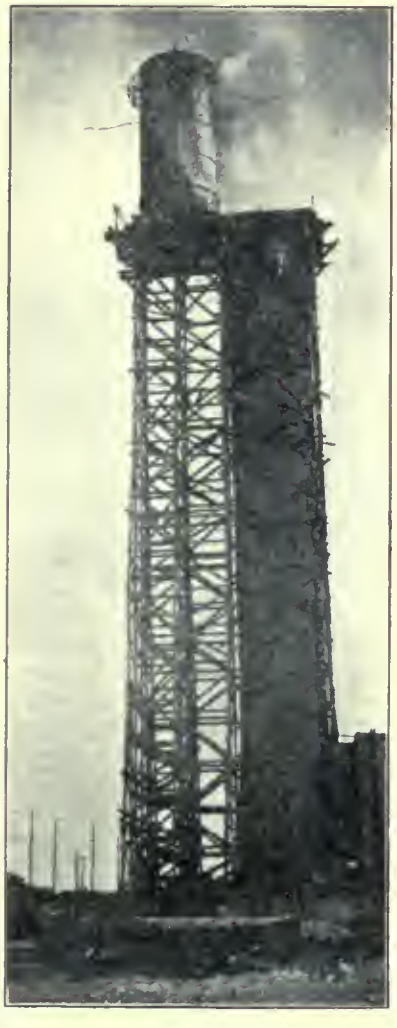


Fig. 1. The New Extension as it Appeared, Completed on the False Work.

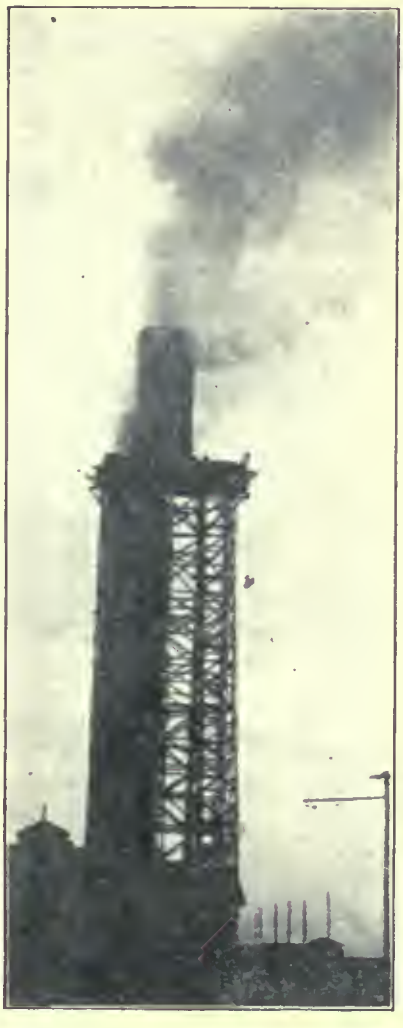

Fig. 2. The New Extension Half-way Over the Original Stack, With Smoke Coming Through Both.

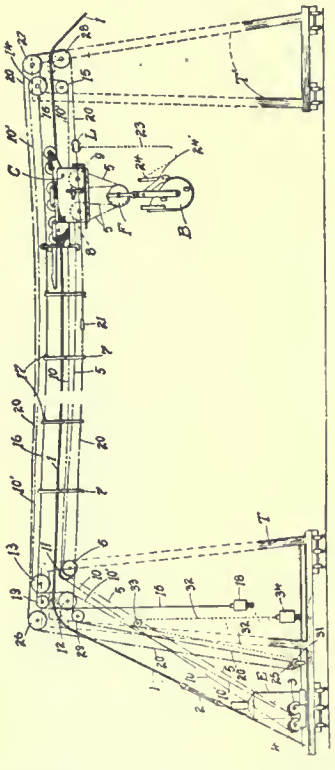
Fig. 3. The New Extension Attached to the Original Stack.

THE British Government has ceased issuing licenses for Chinese labor and the whole system of Chinese importation will cease in South Africa on July 1, 1908.

MINING AND METALLURGICAL PATENTS.

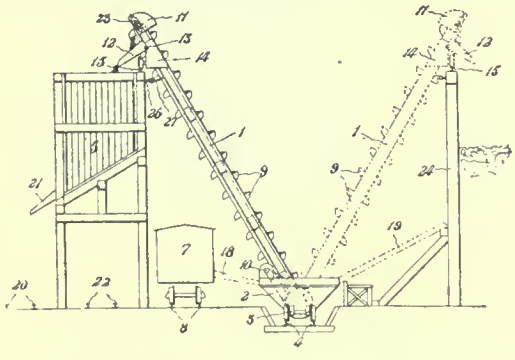
Specially reported for the MINING AND SCIENTIFIC PRESS.

CABLE CONVEYER.—No. 841,858; Ulysses A. Garred, Anaconda, Mont., assignor to Anaconda Copper Mining Co., Anaconda, Mont., a corporation of Montana.



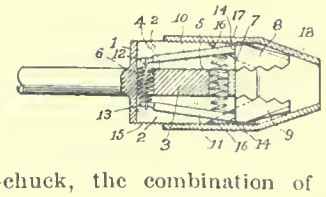
In a cable conveyer, a main cable or way, a suitable traveling carriage, a bucket suspended therefrom, and devices supported independently of the cable adjustable along the path of travel of said carriage for effecting a discharge of the bucket when the carriage has reached a given point.

TRAVELING CONVEYER-CRANE.—No. 841,712; John W. Orrock, Montreal, Quebec, Canada.



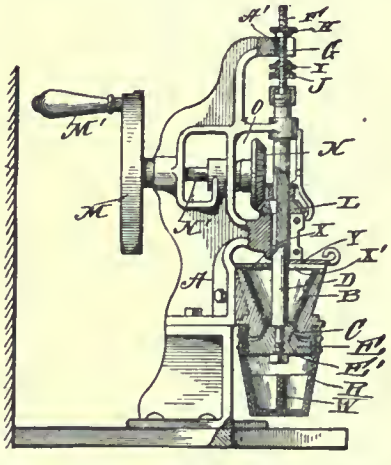
In a conveyer device, the combination with a surface track of a truck mounted thereon, a boot or hopper mounted on said truck, a mast carried by said boot, an elevated track, a carriage supporting the upper end of the mast upon said elevated track, means for delivering material into both sides of said boot or hopper, and a bucket-chain adapted to discharge said material from the upper end of the mast.

DRILL-CHUCK.—No. 841,758; Walter H. Adams, Sound Beach, Connecticut.



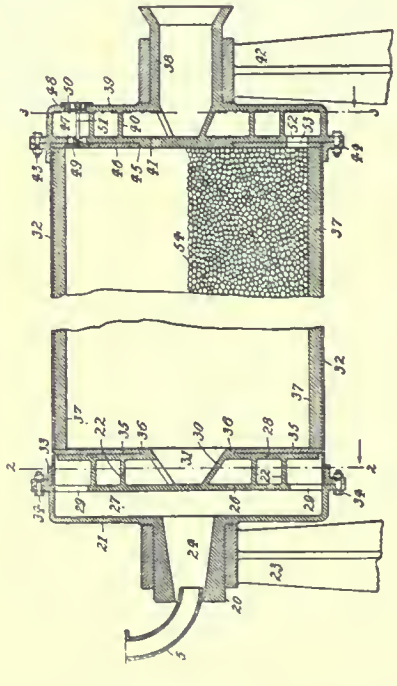
In a drill-chuck, the combination of the exteriorly threaded body having upper and lower channels, whereby a central web is formed which latter has perforations extending therethrough at the rear and front ends thereof, the coil-springs within said perforations, the jaws within said channels and comprising head and tail portions, the free ends of the tail portions being hooked within the opposite ends of the rear coil-springs, which latter have a resilient energy which tends to draw together the extreme ends of said tail portions, while the front portions of these tails are always in contact with the front coil-springs, which latter have a resilient energy that tends to spread the jaws apart, the head portions having a shoulder engagement with the chuck-body, and the interiorly threaded sleeve having a conical front end and adapted to be driven on said body.

COMBINED PULVERIZER AND SAMPLER.—No. 841,921; Oscar C. Beach and Arthur L. Buzzell, Los Angeles, Cal., assignors, by mesne assignments, to Frederick W. Braun, Los Angeles, California.



An apparatus for pulverizing and dividing frangible materials, comprising a frame having a laterally extending arm which is provided with an open slot, a stationary grinding-plate having an opening therein, a screw positioned in said slot and provided with a head at its lower end, a nut mounted upon said screw and resting upon said slotted arm, a vertically mounted shaft swiveled to said head, a grinding-plate fixed to the bottom of said shaft, and means for rotating the latter.

TUBULAR BALL-MILL.—No. 841,841; Max F. Abbé, New York, New York.

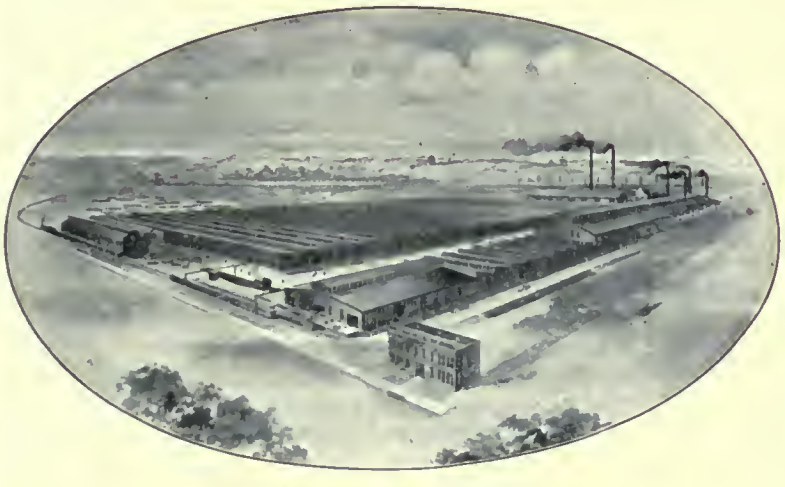


In a tubular ball-mill, a head composed of a flanged end plate, an integral hollow trunnion extending outwardly therefrom, a spiral conveyer extending inwardly therefrom, an inner plate having a beveled flange, and beveled sector-shaped liners engaging said flange.

The American Spiral Pipe Works.

For a number of years the American Spiral Pipe Works of Chicago have enjoyed a large trade in piping for long water-supply lines, hydro-electric plants, compressed air and exhaust steam mains, and the like. Their business grew to such an extent that they were compelled to look for a new and larger site, and after consideration it was decided to stay as close as possible to the centre of the city. They finally obtained four city blocks between 46th and 48th Ave., south of 14th St., where their new works have just been built, comprising a number of buildings. They have three-quarters of a mile of railroad on their grounds, connecting with the Western Indiana Belt Railroad and the Chicago Terminal Transfer Railroad, which are the two main belt lines of Chicago, either of which connects with practically every road entering the city. This is a great advantage in obtaining cars for quick shipment.

The main building, or pipe shop, of brick and mill construction, is well lighted by the saw-tooth roof. This building is devoted exclusively to the manufacture of spiral riveted pipe and heavy sheet metal work. Adjoining the pipe shop is a material shed, of steel construction, where the steel plate used in the manufacture of spiral riveted pipe is received and stored. North of the main shop are the asphalting and galvanizing plants of the testing-room so arranged that the finished product may be tested and galvanized or coated with asphaltum on its way from the shop to the shipping-room. Parallel to and 50 ft. away from the pipe shop are the forge shop, machine shop, stock-room, and shipping-room, all of brick and steel. The forge shop and shipping-room obtain light and ventilation from a monitor in the roof, and the machine shop from a saw-tooth roof similar to the main shop. The forge shop, where there are installed many heavy special machines, is devoted exclusively to the manufacture of forged and rolled steel flanges. Here large quantities of drop forgings, weighing from 100 to 400 lb. each, are handled with great ease and readiness.



The American Spiral Pipe Works.

Taking Machinery Into the Andes.

A new double-drum electrically-driven hoisting engine, built by the Lidgerwood Mfg. Co. for the Inca Mining Co., will have to travel over an interesting and complicated route before it reaches its destination beyond the summit of the Andes in Peru. The Santo Domingo mines, for which the hoist is destined, lie behind the Lake Titicaca region, where the Spanish conquerors found such store of precious metals.

These mines were discovered about twelve years ago by a couple of Peruvians who had wandered across the summit from Arequipa in search of placer gold. They found a vein of gold-bearing ore where a landslide had uncovered the rock. A year later the property was acquired by a party of men from Bradford, Pa., and the Inca Mining Co. was formed. Work was begun about eleven years ago, and more than two and a half million dollars worth of gold has been taken out up to this time. The company has about thirty miles of tunnels, shafts, and drifts opened up.

The hoist, which is now on its way, is to be placed in an adit that has been run 1,700 ft. into the mountain, cutting the vein 1,500 ft. below the outcrop. A 500-ft. shaft has been sunk from the adit, and the new hoist is to bring the ore from the lower workings to this level. Accompanying the hoist are two 200-kw. General Electric generators. These will furnish power to operate the hoist, mill, and other machinery of the mine. The mill contains 10 stamps, a concentrating and a cyaniding plant. The hoist will go by steamer to the port of Moliendo. From there a railroad will take it to the Tirapata in the Lake Titicaca region. There the Inca Mining Co. will receive it and carry it 150 miles over roads of its own building, to the mine. The first part of the way for 100 miles is over a wagon-road, which reaches to the summit of the Andes at Lake Arracoma, 16,000 ft. above the sea-level. The next 50 miles is only a mule-road. To make it possible to transport the big hoist over this part of the route it was built in sections, with no one piece weighing more than 300 lb. The total weight of the hoist is 13,800 lb. The drums are each 48 in. diam. with 40 in. faces. The hoist is designed for a duty of 3,000 lb., to be lifted at a rate of 400 ft. per min. It is driven by a 37-h.p. induction motor of the General Electric make, and operated by a 440-volt alternating current. The power-house is about a mile away from the mill. It is intended to develop about 250 h.p. at first, and this can be doubled by adding another standpipe. The mine lies at an elevation of 5,000 ft. above the sea. Beyond the mine the company has built a road about 75 miles long to the Tambopata river, where it is now putting together a little steel-hulled steamboat for navigating the Tambopata, Madre de Dias, and Beni rivers. At the crossing of the Irambari river the road is carried by a wire-rope suspension bridge 320 ft. long. Telephone lines 250 miles long, belonging to the company, connect the mines with the railroad and points where work is being prosecuted. Photographs of this region and of the road appeared in the MINING AND SCIENTIFIC PRESS of September 22, 1906.

The Insulation of Stationary Boilers.

The development in the covering of steam and fire-heated surfaces is always a subject of interest, since no question of steam-saving can be settled until the matter of proper insulation is taken into account. Some years ago the subject was of minor importance, and not until pressures began to increase, and temperatures to rise, did the subject begin to receive attention. From that time on numerous attempts to prevent radiation by means of covering were made, and although it may seem strange, stable manure was one of the first materials to be used. As the subject was given more thought, attempts were made to improve upon the materials used and for a time organic matter in the form of animal hair, commercially known as 'hair felt,' was employed. The results obtained, while distinctly better, did not solve the problem, for steam-pressures were steadily increasing and furthermore it was found that 'hair felt' became charred and lost most of its non-conducting properties soon after it had been in service. To find a material that would successfully insulate heated surfaces was therefore the problem.

After numerous experiments, it developed that asbestos, a fibrous mineral, could be used for this purpose and accordingly it was made in the form of cement and applied with a trowel. While this was a vast improvement it was found that the material contained two undesirable features. The hard and solid nature of the finished work caused it to be a poor non-conductor and the contraction and expansion of the boiler caused the covering to crack, thus destroying its efficiency. After further experimenting an asbestos 'fire felt' was manufactured. This material does not crack,

flake, or peel off. It is made of flocculent asbestos, formed into sheets and so constructed that by slightly moistening the under side of the sheet, it can be readily applied and will immediately conform to the shape of the boiler. The sheets are made three by two feet, so that there is a minimum amount of joints or cracks between them and they can be made in thicknesses varying from one to three inches. Among several other strong points in its favor is the great amount of dead-air space confined in the material itself, and because of its resilient and elastic qualities and consequent freedom from damage, when walked on, etc., it is the ideal covering for boiler tops, steam-drums, headers, and other surfaces too large to be covered with sectional covering.

The manner of application is very simple: The sheets are strapped to the surface to be covered with cable wire, and are held firmly in place with hexagonal netting. Over the surface of these sheets is applied asbestos cement or magnesia cement, both of which materials present a hard, smooth, and washable finish.

Southeastern Manchuria.

A consular report from Mukden announces the completion of the new Japanese railroad from Antung, on the Korean border, to Mukden, and the prospective industrial development of the Shenking province, through which the railroad passes. Southeastern Shenking is said to be unusually rich in minerals. The mountains contain abundant deposits of coal, iron, copper, lead, silver, and gold. The working of all these deposits has for a long time been carried on by the natives; their methods, however, are of the crudest and the output consequently small. The coal thus far unearthed has been found to be a superior grade of anthracite, and its utilization only awaits capital and the means of bringing it to the market. One of the largest beds yet discovered in this region, and till recently scarcely touched, lies near Penshihu, an important station on the Antung-Mukden railway. Its development was first undertaken by the Chinese in the latter part of 1903, with the result that some fourteen pits were opened. There is another large bed of coal at Niutan, a short distance to the southeast, where about 1,000 coolies were formerly employed in digging, most of the output being sold to the Russians. The Okuragumi, a Japanese concern, a year ago obtained permission from the Chinese Government to work a mine near Penshihu. They have hardly commenced operations, the entire output thus far not exceeding 300 tons, but intend at an early date to use some $100,000 in the construction of shafts and other improvements. The coal is said to be of the best quality, and that taken out so far has been sold to the Japanese Government for use at its iron foundries. Silver has been found chiefly at Antung and Fenghuangchen, near the Yalu river, and was at one time mined by the Chinese; but the work was abandoned owing to the large lawless element which existed among the coolies, and which made operation both unsafe and unprofitable. Thus far the iron wealth seems practically to have lain untouched by the pick. Desultory attempts have been made by the Chinese to utilize it, but the limited returns on the capital invested, the fault of crude methods, as well as the difficulty of bringing the product to market, have made it impossible for the virgin article to hold its own against the old scrap iron entering the country from Newchwang.

Commercial Paragraphs.

THE CRANE CO., of Chicago, announce that their new steel foundry is in full running order.

A. LESCHEN & SONS ROPE CO. publish a handsomely illustrated pamphlet on long distance transportation of ores by aerial wire-rope tramways.

THE BUFFALO FORGE CO., of Buffalo, New York, issue Catalogue No. 77, describing the blacksmith tools and equipment that they manufacture so successfully.

D. H. PALMER, who has been associate manager of the Denver office of FAIRBANKS, MORSE & CO., has been appointed manager of the mining machinery department of this company, with headquarters at the home office at Chicago.

THE DENVER ENGINEERING WORKS CO. has recently secured the contract for all the metal-work of the big U. S. reclamation reservoir in Arizona, in the Salt River valley. This contract consists mainly in supplying huge castings for the outlet gates and pipes.

THE importance and advancement of gas and gasoline as a motive power is indicated by the announcement of the DUBOIS IRON WORKS, DuBois, Pa., a $1,000,000 corporation, which has taken over the entire business of the Lazier Engine Mfg. Co., Buffalo, New York.

THE RISDON IRON & LOCOMOTIVE WORKS of San Francisco report having closed a contract with the Masonic Mountain Gold Mining Co. of Mono county, California, for a 10-stamp mill of the latest type with cast-steel wearing parts throughout; the power plant being large enough for an additional 10 stamps.

The largest order for gas producers ever awarded has been given to THE WELLMAN-SEAVER-MORGAN CO., of Cleveland, by the U. S. Steel Corporation, and calls for 64 Hughes mechanical gas producers for their Duquesne steel works. These producers are to be driven by electric motors, and are equal in gas producing capacity to 160 hand-poked producers. The Hughes mechanical producers attract the attention of steel makers because they require no hand-poking, give a better quality and more uniform supply of gas, and in battery require less room than the hand-poked type of producer.

Books Received.

REGISTER OF CORNELL UNIVERSITY. 1906–1907. This gives useful information concerning the teaching, faculty, and students at the University.

NEW LIGHT ON PETROLEUM OIL, by Jas. W. Wilson. This is a brochure of thirty pages devoted to an interesting account of the "plan and purpose of the oil-systems in the earth." The author is an oil geologist at 923 Stock Exchange Bdg., Chicago.

MINING LAW IN PRACTICE, by G. W. Miller. A handbook, bound in leather, of 300 pages, illustrated. It is a brief treatise on mining rights, correct methods of locating, holding, and acquiring patents to mineral land. Price, $2. For sale by the MINING AND SCIENTIFIC PRESS.

THE ASSAY OF TIN AND ANTIMONY. By L. Parry. A. R. S. M. Published by *The Mining Journal*, London. This is a small book of 50 pages, by a specialist, giving the latest methods for determining the two metals mentioned. As both of them are in demand, it is likely that the book will prove useful. Price $1.50.

THE ENGINEERING INDEX. Vol. IV. 1901–1905. This volume of 1,234 pages is the most valuable reference book of its kind, and is necessary to any mining or metallurgical library. It is published by *The Engineering Magazine*, New York, and has been compiled by the editors of that publication. Incidentally, such an index proves the advisability of giving proper titles to articles and books, so that they really indicate the subject matter.

Publications Received.

REPORT OF THE STATE GEOLOGIST, WYOMING. This includes an interesting account of the exposure of a fraudulent mining scheme and the conviction of the perpetrator.

THE WELLMAN-SEAVER-MORGAN CO., of Cleveland, issue Circular No. GP-1 on the Hughes Continuous Gas Producers. It is well illustrated with photographs and drawings.

THE UTAH MINING MACHINERY & SUPPLY CO., of Salt Lake City, issues Bulletin No. 300, describing the Callow traveling-belt screen. This pamphlet contains an excellent account of the methods of ore dressing involved in the use of this invention, as well as a description of it. The drawings and flow-sheets are numerous, and, as they represent actual milling practice, they will be found valuable to those engaged in the concentration of ore.

MINING AND SCIENTIFIC PRESS

Whole No. 2430. VOLUME XCIV Number 7 "Science has no enemy save the ignorant." THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

Editorial.

THE RICHEST CARLOAD of ore shipped from the Mohawk mine, at Goldfield, Nevada, to the Selby smelter, contained 47 tons assaying 609 ounces of gold per ton. It had a gross value of $591,637; the express charges were $8,800, and the check paid after deducting freight and treatment, amounted to $574,000. On the other hand the thirteen cars that were valued in an Associated Press dispatch at $7,000,000 yielded only $300,000. Fact and fiction are wonderfully blended in the stories that come from Nevada, but it is apparent that the truth is gorgeous enough without further gilding.

OUR ESTEEMED CONTEMPORARY, the *Engineering News*, draws attention to the fact that the resignation of Mr. Charles D. Walcott as director of the Geological Survey to become secretary of the Smithsonian Institution tends to emphasize the absurdity of paying the executive head of a big organization, charged with the expenditure of a million and a half per annum, a salary of only $6,000, while the chief of the Smithsonian, with responsibilities only a fraction of those of the other post, is paid $7,000 per year. It is not that the latter salary is too large, for the position is one of importance, but to pay a man $6,000 for duties that in private or corporate business would entail a payment of $10,000 to $20,000 per annum, is not reasonable. However, the matter does not stop here; geologists who do some of the most important work of the Survey get salaries of $2,500 to $3,000 per annum and this is for scientific investigations for which professional men, under retainer by corporations, receive $7,500 to $10,000. No wonder that the younger members of the Survey are leaving the service of the Government. If the Survey is to maintain its authoritative position as a scientific corps, it will be necessary to have some regard for the sort of pay that equally intelligent and skillful men receive in similar occupations elsewhere.

A LARGE NUMBER of mining papers devote their reading pages to the exposure of fraudulent mining companies and sell their advertising pages to other concerns fully as bad. The inference is fairly obvious, but it is none of our business to press it home. Now, however, the possible seriousness of the situation is lightened by a stroke of humor. Someone on Wall Street has started a sheet called *The Eye-Opener*, the purpose of which, on the surface, is to pillory "the vehicles for wildcats," the names of which appear conspicuously in its issue of January 1. We think that the post-office inspectors ought to pay attention to some of the predatory literature that masquerades in the guise of the investor's friend and the simpleton's guide, but in the meanwhile a little quarreling among them may serve to throw light in

dark places. *The Eye-Opener* attacks the other fellows viciously and advertises several schemes that look no better than any other alluring short cuts to wealth. As a matter of fact, no paper that pretends to give advice on mining matters ought to receive advertisements of mining stocks, the relation between one and the other is too obviously dangerous. *The Eye-Opener* had better undergo treatment himself; his optics look yellow.

A CORRESPONDENT, who is a scientific man, sends us a good story illustrating the varied geological distribution of gold. He was in charge of gold-mining operations in New Zealand, the lode being in an Upper Silurian formation. Within half a mile there was "an old miner pounding away by himself in a tunnel" that was in a Cretaceous-Tertiary formation; this man was getting some rich specimen ore and "strangely enough he was getting coal to sharpen his tools from the same tunnel, he having cut through a small seam of lignite on his way to the lode." We remember also hearing of gold being found, on the west coast of New Zealand, in coal, where an alluvial channel transgressed a coal seam. Some of our readers may be able to contribute other instances of this kind.

Greenwater Again.

In referring again to Greenwater it is not to do that camp an injustice, but to justify a recent criticism, which certain local papers have ventured to impugu. From information just received, we learn that the generalization published in our issue of January 12 was as correct as any general statement can be. There is a good showing of oxidized ore on the surface at several places, and there is a belt extending from twenty to thirty miles that is marked by scattered occurrences of copper ore. In the Greenwater district itself there is as yet no sulphide ore, except for a little chalcocite occasionally found with the copper carbonate—an association that suggests secondary enrichment, itself not encouraging, since this ore in bulk runs less than 10 per cent. There are a number of veins, one or two feet wide, with others, on the Schwab property, that are four or five feet wide, containing ore that, after sorting, will yield some 5 to 8 per cent stuff. It is oxidized ore, and therefore not amenable to concentration. There is no ore in the camp that it will pay to ship at this time, in fact, as we said previously, there is not a carload of 10 per cent ore obtainable. There is no sulphide ore at Greenwater, but at Willow Creek, 18 miles southeast, there is pyritic ore from which some three per cent stuff can be sorted. It amounts to this, that there is a large showing of ore too low-grade to be profitable now and in quantity insufficient as yet to warrant any reduction plant. There are many good-looking prospects, but no mines. Even the Greenwater-Death Valley consolidation, known as the Schwab property, is at the best a hopeful prospect, worthy of development, but not in a condition warranting the sale of stock on the basis of a proved mine. About $3,000,000 has been taken from the public in the name of Greenwater; the fact is, the camp warrants the expenditure of $250,000 in legitimate prospecting; it does not justify the selling of a single share to the public until a thorough test has been made by means of intelligent exploratory work. What reputable mining engineer has reported favorably on the prospects at Greenwater?

Alluvial Mining in California.

The growth of dredging has redeemed alluvial mining in California from a serious decline, for the exploitation of gravel deposits has quite lost its former position of importance. Lode mining for gold and copper has grown to dimensions unexpected at the time when the cream of the placers was gathered during the days of the pioneers, when man had but to help himself to the results of a natural concentration of gold that had been going on for a time longer than human history. The figures for 1906 are not yet available, but those for 1905 show that in that year there were 658 alluvial mines in the State; the distribution of these and their respective yield of gold is shown thus:

	Number	Output	
		1904	1905
Hydraulic mines	227	$1,028,183	$975,140
Dredging companies	26	2,187,040	3,276,143
Drift mines	119	933,954	815,242
Surface placers	286	836,125	825,555
Total	658	$4,985,302	$5,892,080

Thus there was an increase of $906,778, which would have been a decrease of $182,314, had it not been for the gain by dredging. California yielded $19,197,100 in gold during 1905, so that alluvial mining was accountable for only 30 per cent and hydraulic mining for only 5 per cent of the total yield.

Trinity county is first in hydraulic mining, having yielded $370,034 by this method; Siskiyou is second, with $228,291. No other single county in the State gave an output of $100,000 from hydraulic mines during the year. Trinity and Siskiyou are both on the watershed of non-navigable streams and therefore unhindered by the debris problems that have almost made an end of hydraulic mining along the watersheds of the Sacramento and San Joaquin rivers. That region did not yield $500,000 from hydraulic mines. According to the report of the Debris Commission for the year ending June 30, 1906, the total quantity of material mined under permits during twelve months was only 750,000 cubic yards.

Dredging is prospering. In 1905 the yield came mostly from Butte county, to which belongs Oroville. The accompanying figures speak for themselves:

County.	1904	1905	Increase or Decrease.
Butte	$1,632,507	$2,261,888	+$629,381
Calaveras	115,951	202,505	+86,554
Sacramento	348,990	610,672	+261,682
Siskiyou	6,827	7,111	+284
Trinity	8,500	5,000	—3,500
Yuba	74,263	188,967	+114,704
	$2,187,038	$3,276,143	+$1,089,105

In 1906 there was a further increase of at least $500,000. In Yuba county the number of dredges increased from two to ten, although some of these started late in the year. In the Folsom district also there was greater activity, and at Oroville the production has been well maintained. This branch of gold mining will soon be contributing $5,000,000 per annum. It represents a form of industry that affords the basis for sane speculation.

By the Way.

In a recent issue of the *Electrochemical & Metallurgical Industry*, there appears an interesting essay by Mr. Joseph W. Richards, professor of metallurgy in Lehigh University. His subject is 'Rule of Thumb vs. Engineering.' The professor says:

The 'engineer' is one who strives to perfect his work, the 'artisan' works to get through with it; the first labors for intelligent love of his work, the latter "quits when the whistle blows;" the first puts "gray matter" into his labor, the latter only muscle and experience.

Ever since man emerged from pre-historic savagery, the one who weighed chances, measured his resources, and ordered his actions by intelligent foresight, has earned the place and deserved the title of "the fittest." Engaged as we all are in receiving impressions, recording observations, gaining experience, that man alone is wise who profits by this information to lay down rules for the guidance of his future conduct, for the ordering of his future actions.

The English definition of an inch is that it is "the 12th part of a foot, and equal to three barleycorns." The foot was, of course, originally the average length of the pedal extremities of a race of people and it was not only natural, but inevitable that, for example, the French foot should differ in length from the German foot, etc., etc. Not wishing to pursue this branch of our inquiry to too great and perhaps tiresome lengths, we may as well recite at once a striking and suggestive fact, whose connection with our argument may not be at once apparent, namely, the French word for an inch is *pouce*, which is also French for the thumb. The connection implied is, of course, that an inch, in France, at least, and probably in England also, was originally the length of the second joint of the thumb, which varies less in different people than would at first thought be imagined.

In the absence, therefore, of a proper foot rule marked into inches and fractions, it was customary at one time to measure lengths of small dimensions with the thumb joint, and so get an approximation of the number of 'thumbs' in a given length. It would be ill-advised, if not conceited, for us to poke fun at or wax sarcastic about the absurdity of such practice, for the 'rule of thumb' was a valuable practice when compared with what it displaced—no rule at all; and just as imperfect laws are better than total lawlessness, so the 'thumb rule' marked a decided advance toward the arts and sciences.

Somewhere later in time than the period we have been considering, measures of length accurately compared with an arbitrary standard began to multiply and to displace the 'rule of thumb.' Artisans could then begin to work with exactness, the carpenter could plan and scheme ahead accurately by measure, the smith could forge articles to any required stated size, the gentleman could order from his tailor trousers so many inches long, without allowing for the different lengths of thumb of his sartorial 'churls.' This period having arrived, and this stage of advancement in the arts and sciences having been reached, we are now prepared to let loose the vials of our criticism, or, perhaps, indignation, and with perfect justification, upon the unlucky wight, who, either from inborn 'cussedness' or acquired laziness *continues* to afflict humanity with 'the rule of thumb.' Here is the unpordonable sin; the accurately divided rule has come, and the confirmed sinner sticks to his 'thumbs' and 'barleycorns.'

Having dragged the reader through this somewhat misty prologue, it is becoming that we state exactly what we mean to preach further about. It is just this: The difference between 'rule of thumb' and accurate calculation, the wide gulf separating the hit-or-miss cut-and-try methods of the ancients and the scientifically informed practice of the modern technologist. Not that we are going to hold up the former to ridicule or the latter to extravagant adulation, but we wish to discuss some of the features of modern technology which illustrate the great change which has taken place and the still greater changes which are possible.

To take an illustration from civil engineering: Spanning the Firth of Forth, a few miles above Edinburgh, stands the greatest structure of the present time. With clear spans of 1,700 ft., capable of carrying the heaviest trains, the strains and stresses in each of its thousands of members all accurately calculated beforehand, here is a monument to engineering skill absolutely unthinkable as a product of 'rule of thumb.'

Look once more at the electrical engineer and his achievements. A huge dynamo spins like a top on a shaft 160 ft. deep, and develops in the smallest compass imaginable 10,000 h.p. The diameters of the armature wires are accurate to the thousandth of an inch, the hundreds of turns of wire are neither one too few nor one too many, the very phases of the pulsations of the electric waves are mapped and studied out so as to bring out the maximum efficiency. Soft iron from Norway, mica from Canada, rubber from Paraguay, copper from Arizona, shellac from China, steel from Pennsylvania, are combined with the most consummate skill and accurate calculation into a huge giant, which works day and night with almost the regularity of a planet. 'Rule of thumb' could never have conceived of such a product; only 'engineering skill' has made it possible.

One art and one science still bear much of the stigma of 'rule of thumb;" the science of chemistry and the art of metallurgy. Chemistry remained alchemy until the invigorating breath of modern methods commenced to blow away the mists of mystery which enveloped it. The evolution has been long and laborious. Conservatism in the manager combined with stubborn old-fogyism in the workman, have conspired against enlightening methods to keep the industry in the rule-of-thumb rut. Germany was the first country to break away into scientific and engineering chemistry, and the lead thus gained has been maintained to this day. The Britisher, workman or manager, is the most conservative of human beings, and his backwardness in following Germany's methods is the chief cause of the industrial difficulties under which the British chemical industry now labors. Metallurgy is still rule of thumb in many countries, such as Central Africa (production of iron), China (production of lead and mercury), Straights Settlements (reduction of tin), where aboriginal methods still largely survive. But, the aboriginal spirit is preserved in many other so-called civilized countries; it persists among the Cornish and Saxon tin workmen, the Derbyshire and Carinthian lead smelters, the Welsh and Mansfield copper refiners, the Alaskan and Siberian gold winners, the Missouri and the Silesian zinc distillers, the Almaden and Idrian mercury mines, the eastern Peunsylvania as well as the Lithuanian blast-furnaces.

Among all of these, and others too numerous to mention, are to be found that reverence of tradition, that willingness to keep plodding in the rut, that indisposition to apply the discoveries of modern science, that ignorance of what modern science has disclosed, which keep them groping in the semi-darkness of medievalism, while their more intelligent neighbors are running away from them like an express train distancing a stage-coach.

Personal.

F. L. Bosqui is at Tonopah.

J. Parke Channing is at Salt Lake.

Foster Hewett is examining mines in Jalisco, Mexico.

R. H. Channing is in New York. He leaves shortly for Peru.

Courtenay De Kalb is inspecting dredging ground at Oroville.

F. F. Sharpless recently examined the Emma mine, in Colorado.

Forbes Rickard has been examining mines at Butte, Montana.

John Hays Hammond has gone, for his health, to Bermuda.

A. A. Blow recently gave an address at the Columbia School of Mines.

F. N. Fletcher, of Berkeley, has returned from Greenwater, California.

Carl A. Allen is inspecting mining territory near Choix, in Mexico.

L. H. Carver, of Oakland, has gone to Mexico to be absent about three weeks.

Laurence Pitblado has left London for Australia on a tour of professional work.

F. J. H. Merrill is at Nogales, Arizona, where he will remain for several months.

Hudson H. Nicholson, of Chicago, has been examining mines at Goldfield, Nevada.

L. F. S. Holland is re-opening the old Evangeline mine in Halifax county, Nova Scotia.

S. S. Raymond is the new manager of the Brittania smelter at Crofton, Vancouver Island.

Paul Johnson is manager of the Hadley smelter, for the Alaska Smelting & Refining Company.

Grant A. Miller has returned to New York from doing cyanide work in Chihuahua, Mexico.

Chester F. Lee, of Seattle, has inspected the Alaska-Perseverance mine, near Juneau, Alaska.

J. B. Risque, the new general manager for the Utah Copper Co., has assumed his new duties at Salt Lake.

Rupert C. Alabaster has been appointed manager for the Queensland Exploration Co., at Cloncurry, Queensland.

Edgar Collins has resigned as manager of the Combination mine, Goldfield, to take charge of the Montana Tonopah.

D. A. McDonald, dredge-master for the Reliance Dredging Co., of Breckenridge, has returned to that place from California.

R. Gilman Brown has taken up residence at London. He has gone on a visit of inspection to Chile, expecting to return in May.

Martin J. Heller, in conjunction with the changes in the Nipissing board of directors, has resigned as consulting engineer for that company.

George W. Myers has returned to Berkeley from a trip through Arizona and southern California, in course of which he visited the important mining centres.

Walter L. Ehrich is superintendent for the Bonanza Belt Copper Co., which has recently taken over the Peabody mine at Johnson, Cochise county, Arizona.

Samuel W. Osgood, consulting mining engineer, First National Bank Bdg., Chicago, recently examined property of the Pittsburgh Montana Copper Co. near Butte, Montana.

H. R. Plate has resigned the management of the Nevada United Mines Co. and for the next few months will remain at Ely, Nevada. Mr. Plate will resume his professional practice, which he had practically discontinued during his term of office with the above company, and will be pleased to examine and report upon properties in the Ely district.

Charles W. Saxman, former manager of the Keystone Coal & Coke Co., with headquarters at Pittsburg, Pa., has been appointed general manager for the mining interests operated under the control of Capt. Henry Stern and associates of New York. This includes the Yampa mine and smelter at Bingham, Utah, and the Britannia mine and smelter in British Columbia.

Trade Treatises.

The C. L. Hathaway Rock Crusher Co. has published Catalogue No. 1, describing their well-known gyratory crusher.

The Ingersoll-Rand Co., of New York, issues an attractive pamphlet describing the Davis calyx diamondless core-drill.

Jenkins Bros., of New York and Chicago, issue a handsome catalogue describing and illustrating the valves, packing, and discs that they manufacture so successfully.

The Atlas Engine Works, of Indianapolis, publish Bulletin No. 134, describing the various types of steam-engines and boilers built at this important establishment.

Mining Summary.

ALASKA.

NOME.

Boilers and prospecting outfits have recently left Nome for Center creek; the Good Hope property on Irene creek; for the Daniels-Seward property at Bluff, for Arctic creek; and many other points, showing a wholesome activity in the hills. ——Warnings have been issued relative to the stampede to the Chandelar district. No one, it is stated, should go into that country without an outfit. There is no store nearer to the diggings than Coldfoot, which is 65 miles distant, and the only other outfit-stations are Circle; Fort Yukon, which is 162 miles away; and Bettles, 130 miles distant. The strike on the Chandelar seems to be of a substantial character. The principal finds are between the north and middle forks, and on Squaw, Little Squaw, and Big creeks. The gold is in the gravel, and rather deep. The Myrtle creek diggings were deserted in the rush to Chandelar.——The Omilak silver mines have several shafts about 60 ft. deep. The ore carries gold and lead, but silver is the principal metal. These mines have been working continuously for several years, but shipping charges are so high that no great profits have been realized.

ARIZONA.

COCHISE COUNTY.

The Shattuck-Arizona company at Bisbee is working 350 men on its property, and is shipping over 300 tons per day to the Copper Queen smelter at Douglas. Mining is now confined principally to the 700 and 800-ft. levels, but the shaft will soon be down to the 900 level.——At the Calumet & Arizona, there are four connecting drifts between the Irish Mag and the Oliver shafts, a distance of 1,900 ft. These connecting drifts are on the 850, 950, 1,150, and 1,250 levels. A new strike is reported on the Buckeye claim of this company, to the south of the Oliver shaft. The ore discovered is an oxide and sulphide, but it will not be stoped at this time, and work will be confined to development.——The Bisbee Extension Development Co., was recently formed here to work a group of claims over the divide, west of the city. The capitalization is 40,000 shares of $10 each. F. L. Harrington is president. The 21 claims of the group are situated about 10 miles from Bisbee.——Official announcement has been made of the apportionment of shares in the new mining company which has been formed to take over the Denn-Arizona Development Co. Three and one-third shares of the new stock will be issued for one of the old, with the privilege of subscribing for one and one-third shares of the new, at the par value of $10.——On account of the cave-in at the Holbrook shaft, the Spray shaft of the Copper Queen Co. is kept very busy. A new 150-h.p. marine boiler will be installed at this shaft. The Holbrook is again in good repair and will be started at once.——The shaft of the Pittsburg & Duluth is not working, and ore from this mine is handled through the Lake Superior & Pittsburg shaft.——The American-Saginaw shaft is down 960 ft. Driving was commenced on the 870 level, and has continued 1,600 ft. toward the Dean property.——The main shaft of the Tombstone Consolidated Co. is now down 1,020 ft., a gain in depth of about 200 ft. in the last two years. The company continues to ship some ore, although the water problem is a serious one and pumping operations very expensive. This is one of the chief properties in the Tombstone district, and it is hoped that it will become a large producer. Many of the old stopes contain low-grade ore which was used for filling, when the property was originally operated, and this material furnishes the bulk of the ore now mined. J. H. Macia is in charge of all mining operations.——A new boiler and hoist is being installed at the Herschel mine in this county. The shaft is down 350 ft. and will be sunk to the 600-ft. level at once. The mine was worked as early as 1880, and although the vein is small, its values are good and have proved continuous. About two carloads of ore per month are shipped to the El Paso smelter.——Steady work is reported in the Dragoon Mtn. The Peabody will have a new hoist, and it is expected to ship 100 tons per day.

YAVAPAI COUNTY.

(Special Correspondence).—Sinking in the working shaft of the Gazelle mine, at Crown King, now down 200 ft., has been discontinued for the present. At the bottom of the shaft the vein was cross-cut and was found to be almost 40 ft. wide. A drift is being run to the north to get under the ore-shoot, which outcrops at the surface about 150 ft. north of the shaft. G. F. Harrington has taken charge of the Gazelle mine.—— The Consolidated Union-Grand Copper Co., at Silver Mtn., has been closed temporarily. The company expects to build a wagon road from Harrington to its property, and will then put in heavier machinery.——While doing assessment work on the Enid group of claims a nice body of gold-bearing zinc and copper ore was unearthed. The Enid group lies on the War Eagle vein, to the north of the Gladiator, and just west of the new strike on the Gold King. Bernard Cunniff, from Prescott, is at the Savoy camp, arranging for the development of the property. A carload of ore was shipped to the Humboldt smelter this week.—— The construction of a stamp-mill and extensive development of the Winifred group of claims, near Wickenburg, will be commenced soon. James Boyd is owner of the property, and James E. Boyd, of Nevada, will direct the work.—— O. A. Pease, from the Quartzite district, says there is great activity in that part of the country. There are about 400 men at work.

Map of Arizona.

CALIFORNIA.

ELDORADO COUNTY.

The old Excelsior mine is the centre of interest in the vicinity of Placerville. There are over 6,000 ft. of drifts and cross-cuts, and the main tunnel is in 3,000 ft., and a good body of pay-gravel has been opened. Fifteen men are employed, and a 10-stamp mill has just been completed on the property.

NEVADA COUNTY.

Operations have commenced at the McPherran mine, near Graniteville. This property was recently bonded, and a new tunnel will be run under the Bloomfield ditch, which will cut the lode at a good depth.—— The Round Mountain Champion mine will soon be worked again. A part interest in this property, near Selby Flat, was recently sold to H. Goering and W. L. Clark.—— Two loads of ore from the Chicago mine on Gold Flat were hauled to the Pioneer Reduction works.—— The Cornish pump at the Niagara mine, at Grass Valley, has been started, and the lower levels will soon be unwatered. A good strike was made in the east drift at a distance of 300 ft. from the shaft. A

Phoenix, Feb. 11.

15-stamp mill at the property is in good order.—— A shoot of good antimony ore has been encountered in the south drift of the Tightner mine, about 100 ft. from the shaft. Three shifts are working on the lower tunnel, and 300 ft. has been driven in the last four months.——A vein has been cut in the tunnel of the Giant King mine, near Washington. The upper tunnel is in 570 ft., and good milling ore has been cut. The company expects to erect a 20-stamp mill soon.

PLACER COUNTY.

The big arastras at Bunts cañon, near Colfax, are working steadily.——It is reported that the old Crater mine will be pumped out. No work has been done on this property for 20 years.——At the Three Star mine, the shaft is down 1,100 ft., and about 35 men are employed. A 20-stamp mill is on the property, and 10 stamps are run continuously.

The Bellevue mine, near Ophir, has been sold to W. F. Briee, of Los Angeles. This is one of the oldest mines in the district, and the shaft is down 300 ft., and will be sunk farther at once. None of the eastern Ophir shafts are down lower than 800 ft. The purchasers are negotiating the purchase of the Eclipse, Morning Star, and Gold Blossom properties.——The Gold Run Gravel Mine Co. is putting in new compressors .and other improvements.——Two shifts are working at the White Oak, and are making about 25 ft. per week.

SHASTA COUNTY.

Three carloads of chromite ore have been shipped from the Shasta County mine, at the base of Castle Crags. The demand is limited for this class of material, which has netted the owners $15 per ton.——A carload of machinery has arrived at Redding, for the Midas mine in Harrison gulch. The shipment includes a hoisting equipment for the new shaft.

SISKIYOU COUNTY.

There is an abundance of water for the Horse Creek hydraulic mine, near Oak Bar.—— The Poverty Point mine on Klamath river will be worked in the spring.—— The Morrison & Carlock quartz mine in Quartz valley employs a large force of men, and the prospects are promising.—— A new company has taken over the old Rusby mine and mill on Deadwood creek. The mill will be started at once.—— Holt & Gregg have a contract to ship a carload of limestone per day to the Keswick smelter.

TUOLUMNE COUNTY.

(Special Correspondence).— Unwatering of the Santa Ysabel mine, situated near Jamestown, will be commenced shortly, and it is understood that extensive development is contemplated. B. C. Austin, formerly superintendent of the Oneida mine, in Amador county, has been employed to act in the same capacity at the Santa Ysabel.——Operations have been temporarily discontinued at the Patterson mine, near Tuttletown. At the bottom of the winze the vein is three feet wide, all good milling ore.——The Bourben mine, consisting of five claims, and situated between Knights creek and the Stanislaus river, was last week purchased by W. E. Mitehell, of New York. Development work will be continued on an extensive scale.

An Eastern syndicate is investigating the Draper mine, near Soulsbyville, with a view to purchasing the property.—— At the Jumper mine, near Stent, 45 men are employed and 20 stamps are dropping, and at the Shawmut, at Jacksonville, 170 men are employed, and at least 30 more will be added to the force within the next few weeks.

Tuolumne, Feb. 11.

YUBA COUNTY.

P. J. Williams has been elected president of The Marysville Tunnel & Quartz Mining Co. This company owns claims at the Narrows, on the Yuba river. The original plan of draining the bed of the river has been abandoned, and excavating machinery will be installed.——The Pacific Gold Dredging Co., which owns the dredging rights on 13,000 ft. of the Sacramento river, between Keswick and Coram, has been organized, with a capital of $500,000. It will construct a suction dredge, which will be completed by spring.

A 400-acre plat, belonging to N. F. Mahle, in the vicinity of Honcut, has been bonded to parties that intend to build two dredges to work the property.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The sale of the Arapahoe group of claims, in East Argentine, is reported. The property was purchased by English capitalists for $58,000. A company is being organized and active development will shortly follow. This property has produced ore which milled as high as 500 oz. gold and 4,000 oz. silver per ton. Carsen & Swanton have secured a group of 15 claims, situated on Payne's peak. An adit is being driven to intersect the entire group at good depth. Ore has been exposed and shipments should soon start. The holdings lie to the west of the Vidler tunnel. The Mazeppa group of five claims has been sold to M. Jacoby of Duluth for $4,000. The claims are on Democrat Mtn., and are surrounded by a number of producers. Driving is being done on the Mazeppa lode, intersected at a distance of 475 ft. from the portal of the adit, and the ore measures six feet across, with an average value of from $12 to $14 per ton, silver.——A heavy tonnage of ore is being extracted in the Bellevue-Hudson, situated on Columbian Mtn. The lessees, A. D. Bryan & Co., are shipping one carload per week, which returns 225 oz. silver per ton. Hancock Bros. have one of the rich leases of the district. They are working on the west Phillips drift, owned by the Dives-Pelican & Seven-Thirty Mining Co., and are stoping on a two-foot body of $60 silver-lead ore. A portion of the product is shipped to the Newton mill at Idaho Springs for concentration. The Jewell M. M. & L. Co. employ a force of men in the construction of the new 50-ton concentrator. The building has been enclosed and the machinery is being delivered. This plant is to be run on dump-material from the Frostberg and Mendota mines, situated on Sherman Mtn. The aerial tramway running to the railroad will be put in use, the terminus having been changed so that the ore can be dumped direct into the mill bins.——B. J. O'Connell, leasing on the Frostberg, through the Victoria tunnel, is mining 100 tons per week. The ore contains lead and zinc, and is worth $40 per ton. It is concentrated.—John Schuler has a rich block of ground on the Bismark vein. He is working through the Hercules tunnel and has a one-foot body of ore which averages $100 per ton. Riley & Roehrl have broken into a three-foot body of 600-oz. ore in the Sunburst. A blind drift is now being driven and as soon as the ground has been opened for 80 ft., the stope will again be carried. These lessees are at work 600 ft. from the portal of the adit and have a block of ground 100 ft. in length by 70 ft. in height. Pat Walsh, operating the Little Emma under bond and lease is mining 175-oz. silver ore. The discovery was made in running an adit under the upper workings, which produced $350,000 a number of years ago.——A big strike has been made in the upper Paymaster workings, owned by the Waldorf company. The orebody measures from 18 in. to two feet in thickness and the ground has been opened for 120 ft. The ore runs $90 per ton in gold, silver, and lead. Coggswell Bros. have this property under lease. Another strike in the same company's holdings has been made on the Commonwealth vein, intersected through the Wilcox tunnel workings at a distance of 3,750 ft. from the portal. Drifts have been run for 700 ft. east and west and the orebody measures from two to six feet in width, containing values in gold, silver, copper, and lead of $90 per ton. This is the most important strike made in recent years in East Argentine.——The 75-ton concentrating plant of the Transcontinental Transportation & Mining Co., is running at its full capacity. The plant is supplied from the Flossie lode, intersected at a distance of 1,000 ft. from the portal of the Vidler tunnel. Shipments will start as soon as the Argentine Central railroad is open.——Another strike is reported from the Ramsdell. In running the west drift a body of ore measuring 10 ft. in width has been exposed and a sample gave the following results: Gold, 31.41 oz., silver, 23.6 oz. per ton, and lead, 14%. Shipments are to be made direct to the Denver smelters. G. W. Teagarden announces that the working force will be increased at once.

Georgetown, Feb. 8.

The Newhouse tunnel is now in 17,477 ft., having been advanced 195 ft. during the month of January. It is announced that driving in the breast will be discontinued for

an indefinite period, which decision is supposed to be due to the lack of co-operation by the mine-owners benefited by the tunnel. A number of veins have been encountered in the last half-mile of driving, but they have all been low-grade, running from $3.50 to $11 per ton.

SUMMIT COUNTY.

(Special Correspondence).—A shipment of a carload of rich lead carbonate ore has just been made from the Dunkin property from a lease held by Knorr, Kistler & Co. This property was one of the rich mines in the early history of Breckenridge.——The New York group of claims on Gibson hill is being worked by a company and a trial shipment of a complex lead-zinc-iron-sulphide ore was sent to the sampler this week to ascertain how the product can best be treated.——As long as the Colorado & Southern Railway Co. can supply the cars, the Wellington Co. can ship 75 or 80 tons per day. The ore is high-grade zinc, and goes to the Colorado Zinc Co.'s plant in Denver. Shortage of cars is the only drawback at present.——The Senator mine has 20 miners taking out ore to ship when the roads open in the spring.——The Abundance M. & M. Co. will hold its annual meeting in Kansas City this week. S. B. Prevost is the president.——H. T. Keltie, president of the Washington Joliet company, is at the mine with W. R. Everett, of Chicago, who is considering the purchase of the property. F. H. Summeril, of Denver, is making the examination for the Chicago people.——The Sundown Placer property is being put into shape for work this year. It is situated in Illinois gulch and is owned by Wm. Squires and associates. Prospecting has shown placer gold to exist in paying quantities.——D. A. McDonald, of the Reliance Dredging Co., has returned to Breckenridge and commenced repairing the dredgeboat on the French Creek property. It is likely that the steam-power plant will be replaced by electric power. ——The Gibson Hill Mining Co. is a new incorporation of a group of properties on Gibson hill. The incorporators are B. W. Newcomb, O. W. Pitcher, Geo. Kellog, and W. F. Forman. The authorized capital is $300,000.——The Kimberly Consolidated, at Kokomo, is employing 80 men on the construction of its new mill for treatment of lead-zinc ores. This property can produce plenty of ore for the new plant to work on.——The Rothschild mine, at Rathbone, made a shipment of a carload of high-grade silver ore this week. This ore was obtained from the main tunnel workings in Cooper Mtn. Thos. Webb is the superintendent.——The Hibbs M. & M. Co. is operating the Victoria mine on Mt. Royal, at Frisco, and is employing three shifts of men in sinking the main shaft. A good streak of ore has been cut in the shaft. J. Percy Hart is in charge of the work.

Breckenridge, Feb. 4.

IDAHO.

OWYHEE COUNTY.

The new filter-presses that have been installed in the DeLamar mill are working satisfactorily, and the property is now running on a paying basis. The supply of fuel is very short, however, and the property may have to shut down again before spring, and wait for warm weather, when the mill can be run by water-power.——The new machinery for the Potosi mine has arrived and is being put in place. In the meantime work has been suspended in the mine with the exception of the cross-cut from the No. 2 level north to cut under the old Knickerbocker shaft. The new electrically driven air-compressor will soon be working, when a full force of men will be used again in the mine.

SHOSHONE COUNTY.

(Special Correspondence).—The Idaho Northern Railroad Co. was organized several months ago to construct a railroad from Enaville, a point on the line of the Oregon Railroad & Navigation Co., up the north fork of the Coeur d'Alene river to the mouth of Prichard creek, thence up the latter creek by way of Murray to the vicinity of the Bear Top, Monarch, Paragon, and Chicago-London mines. The length of the line will be 33 miles. Surveys have been made, the enterprise has been financed and plans contemplate the building of the road this year. B. F. O'Neil, of the State Bank of Commerce, of Wallace, is president, and E. P. Spalding, manager of the Monarch Mining Co., is vice-president. The development of the mines in the Murray district has made such a road a necessity and an attractive enterprise.——The Monarch group is situated on the south side of Prichard creek, five miles east of Murray. Its holdings extend from the bottom of this creek over a mountain spur and down 1,000 ft. on the southern slope. The first development was through levels from the latter side. Later a 3,300-ft. cross-cut was driven from the Prichard creek side, cutting three veins, on which a considerable amount of driving has been done. This cross-cut intersects the vein system 800 ft. vertically below the upper workings. Several cars of ore were shipped which ran 65 to 72% lead and 12 oz. silver. The gangue is quartz and the country is quartzite and slate, being similar to the Burke formation. A 75-ton concentrator has been built at the portal of the main cross-cut. The capacity of this may be increased later.——The Terrible-Edith, developed by Wash. Snyder and others, has been bonded to Butte parties. This is in a good grade of silver-lead ore and a cross-cut is being driven to obtain 400 ft. greater depth.——The Chicago-London and Paragon, managed by L. W. Stedman, have been persistently developed for several years. A compressor plant and saw-mill have been installed and good buildings have been erected.——The Bear Top mine, which is well developed, is driving a long cross-cut to obtain 439 ft. greater depth. The mill is operating with a capacity of 150 tons per day. George J. Kiebler is the new manager. The Orofino and Great Western groups are bonded to Missoula people, who are developing.——The Golden Chist, a gold property near Murray, is now in charge of Herbert S. Auerbach, of Salt Lake, who is driving a lower cross-cut and is preparing to start the mill in operation again. It is estimated that 250 men are employed in Murray district, practically all on development.

Wallace, Feb. 5.

NEVADA.

NYE COUNTY.

(Special Correspondence).—The weather conditions have improved, freight and supplies are arriving, and automobile travel has been resumed.——In the Mustang, a cross-cut has been started from the drift on the 210-ft. level. The recently opened vein on this level is four feet wide. The company contemplates sinking on the Buyo claim, near the Chipmunk.—— Work has been resumed on all the local properties controlled by the Sullivan Trust Co. On the Stray Dog sulphides have been encountered at a depth of 165 ft.—— The lode is four feet between the walls and pans free gold.—— On the Carson, a 700-ft. tunnel is to be run from near the Tonopah road. The shaft is down 175 ft.—— The Santa Lola ground is being opened by a cross-cut tunnel which is now in 360 ft.—— A four-foot vein averaging $4 per ton is being developed at a depth of 90 ft. on the property of the Manhattan High Grade Mining Co.—— The Whale shaft is down 115 ft., and at this depth a cross-cut has been run 180 ft. toward the Stray Dog.——Recent measurements of the ore-dumps on leases 9, 10, 11, 12, and 13 on the Union No. 9 claim, and on lease 13 on the Little Grey, show 4,000 tons of ore, which is reported to average $33 per ton. On the Union No. 9 there is a dump at lease No. 3. Ore has been shipped from these leases and the dumps represent the milling ore.—— Several properties have changed hands at Superior. The Nevada Superior Con. Copper Co. has let a contract for a 100-ft. shaft.

Manhattan, Feb. 8.

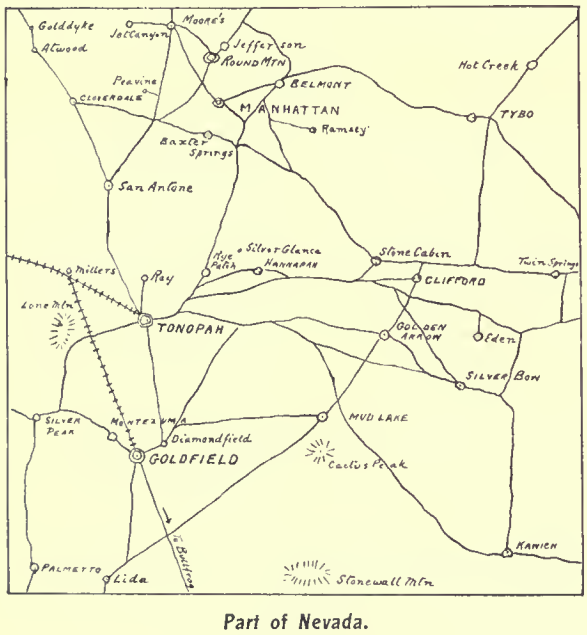
LINCOLN COUNTY.

(Special Correspondence).—F. J. Spare, the superintendent of the Pompeii and Lee Roy mines, has let a contract on the Lee Roy, and has a force of men building a headframe at the new shaft. The machinery for the mine is now on the ground.——The Philadelphia Searchlight Gold & Copper Co. has opened a vein on its property at McGahn camp, and a sample taken across 15 ft. gave returns of $17 per ton. Geo. P. Spittall, the agent for the company, has ordered a carload of machinery and building material from Los Angeles.——G. F. Coleman, the manager of the Duplex mine, is making preparations to sink 1,000 ft. on the New Years Gift. The shaft on this claim is now 260 ft. deep and is equipped with a small hoist, which will be replaced with heavier machinery.——On the Wyoming Searchlight the

development of the past week has shown that the orebody is holding well. A short drift has been cut through the ore, but it was found that the supposed wall was only a horse in the vein and back of it the drift opened up four more feet of good ore. The shaft has now reached the 300-ft. level and Mr. Carlson expects to begin driving on this level as soon as the station is completed.——Mr. Weinke is superintendent of the Irwin Consolidated mine at El Dorado cañon. He reports an important strike in the tunnel on that property of four feet of ore that assays $50 per ton. ——A lease has been given on the Jumper mine owned John Anderson. This property has produced some high-grade silver ore.——E. P. Jeans, of the Black Hawk mine, passed through Searchlight on his way to Los Angeles, where he will arrange for the immediate shipment of machinery. He reports that the mine is in fine condition, the shaft is down 315 ft., and in sulphide ore which runs $40 per ton.——E. J. Roberts, the superintendent of the Eldorado-Nevada Mining & Milling Co. has resigned in favor of H. E. Spanogle, who is one of the stockholders of the company.

Searchlight, Feb. 7.

(Special Correspondence).—Crescent is fortunate in the matter of transportation. The Salt Lake system has a station at Nipton, Cal., five miles distant, while the Santa Fe system, which is rapidly building into Searchlight, will have a station on the east of the Crescent hills, from which terminal a road is being built to Crescent, a distance of 11 miles. The cost of transportation of ores to the Salt Lake smelters is $5 per ton, while on the Santa Fe the rate from



Part of Nevada.

Ivanpah to the Needles smelter is $1 per ton.——Water for milling and domestic purposes has been developed and the building of an electric light and power plant is under discussion by Los Angeles capitalists.——The Golden Crescent Co. is running an adit on the vein that crops on the north side of the Crescent hills. The adit is now in 225 ft. Over 500 ft. of work has been done on the vein and good milling ore is opened. A. J. Waddleton is the superintendent. This mine has been working for the past two years.——The Red Star group, consisting of three claims, situated two miles south of Crescent, has been purchased by Samuel McMillen and associates, of Goldfield.

Crescent, Feb. 2.

(Special Correspondence).—Eldorado Canyon is coming to the front faster than any district in Nevada. New wagon roads are being constructed to the Salt Lake System at Jean, 20 miles distant, and the Santa Fe is near Searchlight. The cost of shipping and treating ore was about $75 per ton, but, with reasonable shipping charges, ore averaging around $40 per ton can now be treated at the Salt Lake smelters. At the bottom of the deepest shaft in the district, on the Techaticup, which is down 675 ft., four feet of ore running $600 per ton has been opened. The vein has been followed from the surface. This property is owned by Joseph Wharton of Philadelphia.——Among other properties in the cañon are: The Wall Street, that produced two million dollars from an open stope at the surface: the Quaker City, that has ore exposed; and thirteen other claims, all showing ore.——The new camp is called Nelson, has a post-office, telephone connections with Searchlight, Nipton, Cal., Manvel, and Crescent, and a wire to Front, on the Santa Fe, between Manvel and Searchlight. Water has been developed in many of the properties at a depth of about 225 ft., and the district abounds in springs.——Later companies are: The Honolulu El Dorado, El Dorado Consolidated, El Dorado Nevada, and the Black Hawk companies. The Honolulu El Dorado is in the centre of the district, and a shaft is being sunk to water-level. At this level, cross-cuts are to be run to the Wall Street vein, that is pitching to the north at an angle of 45°. The shaft is 50 ft. deep. The company has leased a spring a few hundred feet distant until they develop sufficient water in the mine. Other properties owned by this company are the Kobe, Manila, Nagasaki, and Hong Kong claims. These claims have been thoroughly prospected on the surface. On the El Dorado Consolidated, samples of specimen ore have been taken from the Kensington claim, where a 5 by 7 ft. shaft is being sunk. The ore is an iron-stained quartz, carrying gold, silver, and galena, and the property is on the strike of the Silver Legion mine of the El Dorado Nevada Co. The El Dorado Consolidated is owned by Jas. T. Wisner.—— The Black Hawk, Silver Sphinx, and Magnolia mines report new finds. Machinery for the Black Hawk, El Dorado Nevada, and Silver Sphinx has been shipped from Salt Lake.

Eldorado Canyon, Feb. 4.

NEW MEXICO.

TRES PIEDRAS COUNTY.

After months of delay, all the machinery for the smelter of the Southwest Smelting & Refining Co., has been received and installed, and the furnaces will blow in at once. Much development work has been done in the mines of the district, in anticipation of the starting of the smelter. The orebodies are not generally high-grade, but they are extensive, and the ores are practically self-fluxing. Tracks have been laid from many of the largest properties, to the smelter, and shipping can commence at short notice.——The Excelsior company, owning several claims in the district, will equip its properties with new machinery, and the Amarillo company, a Boston concern, will push development work.—— The Rio Chama Gold Dredging Co., has purchased 1,200 acres near Vado, Rio Arriba county, and will install a dredge and begin operations in about three months.——Good bodies of copper ore are being found in the Burro Mtn. The most recent strikes are on the property owned by M. W. Porterfield, between Tyrone and Leopold, and on the Robinson group, about half a mile from the Leopold mill.

OREGON.

BAKER COUNTY.

The annual meeting of the stockholders of the Highland Co. was recently held and a new directorate elected. The office of the company was changed from Sumpter to Baker City.——A good vein has been opened on the property of the Sovereign company on Coin creek, 30 miles east of Baker City. John Arthur is the superintendent.——Electricity for power purposes will soon be ready for the Virtue mine. A large force of men is employed under C. P. Loomis, the superintendent.——The placer strike on Boulder creek is still attracting a good deal of attention, and favorable reports are coming from the district.

GRANT COUNTY.

The Glade creek placers, situated 15 miles east of Granite, on the north fork of John Day river, have been bonded by A. J. Dickison to N. Berkeley, who represents an Eastern corporation. There are 160 acres in the property, and have been worked for several years. The gravel bank stands 30 feet high, and the ground has been thoroughly prospected

and promises well.——The tunnel in the Ben Harrison property has now gained a depth of 200 ft. and the vein is reported to be widening in the breast.——The Alamo mine has an adit in on the vein, and good ore has been encountered. A. B. Pierce is the superintendent.

JACKSON COUNTY.

(Special Correspondence).—The Opp mine, at Jacksonville, has been operated intermittently since 1867. It is now owned by the Opp Consolidated Mines Co., of which H. E. Foster is superintendent. The ore-shoots, which pitch to the east, are in a fissure vein that cuts through slate and diorite. The orebodies are developed by five cross-cuts, the vertical distance between the highest and lowest being 700 ft. The ore is taken out through the lowest cross-cut, which is on a level with the crusher-floor of the mill. The ore carries free gold, iron pyrite, and petzite, in a quartz gangue. About 40% of the gold is recovered by amalgamation. The mill is equipped with 20 stamps, tables, and vanners; 20 additional stamps are being installed. With this method serious losses have occurred, in that much of the telluride would float away in the slime. To stop these losses, a roasting-furnace of the Stedtefeldt type has been built, in which the entire product of the mine will be roasted before milling, the object being to volatilize the selenides and tellurides. The experiments made prior to the erection of the roaster convinced the management that this type of furnace, which affords a thorough oxidizing roast, would put the ore in shape—to save the values by amalgamation and concentration. Wood is to be used as fuel in the furnace, which will consume six cords of wood for 20 tons of ore, at a cost of 40c. per ton. The new roaster will be in use in a few weeks.

Jacksonville, Feb. 2.

(Special Correspondence).—C. W. Evans, the manager for the Cyanide Gold Mining Co., of Ashland, reports the property fairly well developed, with gold-bearing quartz in one vein and ore containing cinnabar in the other. A cyanide plant will be erected to treat the gold ore and an equipment will be provided to retort the cinnabar.——The Harms Mining Co., having offices in Ashland and New York, is developing the Briggs property in Josephine county, having 2,000 ft. of work done. The same company is opening a property on Forest creek, near Jacksonville and one on Sardine creek, near Gold Hill. A car of ore shipped from the latter ran $60 per ton. It is announced by E. T. Staples, the superintendent, that a mill will be erected this spring at each of the properties at Gold Hill and Jacksonville.——The Shorty-Hope M. & M. Co., having a property three miles from Ashland, is managed by C. T. Sanford. Considerable development has been done and there is ore in the stopes. It is a gold ore, partially free-milling, but the greater part is carried in the sulphides. Experiments are being made to determine the best method of extraction, and the company may adopt roasting and cyanidation.

Ashland, Feb. 6.

SOUTH DAKOTA.

LAWRENCE COUNTY.

The miners employed at the Maitland property at Garden City have demanded an eight-hour day. A similar demand has been made upon the Minnesota company, operating near there. Manager F. R. Baldwin, of the Maitland, has gone to Chicago to confer with the owner of the property and will give his answer to the men in a few days. The Minnesota has just finished the foundations for a new cyanide plant, and expects to begin milling this summer.

UTAH.

BOX ELDER COUNTY.

(Special Correspondence).—The Southern Pacific Railroad has just completed the location survey for a spur five miles in length from Tecoma to the lower terminal of the aerial tramway being installed by the A. Leschen & Sons Rope Co., of St. Louis, for the Salt Lake Copper Co., of Salt Lake. This tramway will be nearly three miles long and known as the Leschen-Riblett system. It is understood that work will be started on the spur at once. Ore is now being hauled by wagon eight miles to the railroad, and shipped to the U. S. Smelter at Salt Lake. This mine is owned by Lewisohn Bros., of New York, and R. S. McCaffery, of Salt Lake, is the manager.

Tecoma, Feb. 11.

WASHINGTON.

SNOHOMISH COUNTY.

(Special Correspondence).—The Seattle-Boston Copper Co., of Seattle, is operating in the Burns mining district, on the west slope of the Cascade range. The purpose is to build a railroad, from Foss river on the line of the Great Northern, to their camp, and erect a tramway. The company has contracted to take out 75,000 tons of ore. Within the last ninety days 93 ft. of sinking and 75 ft. of driving has been done. The ore runs from 1½ to 28% copper, averaging about 7%.——The Pittsburg-Gold Mountain Mining Co. is developing at Darlington, in Snohomish county, and has an experimental plant for testing its copper ores. A larger plant is contemplated.

Portland, Feb. 1.

STEVENS COUNTY.

(Special Correspondence).—Native copper has been found in the vein of the Lucky Bill mine, four and a half miles east of Northport. The ore was found in the face of the drift-tunnel, now in 200 ft., with a depth of 40 ft. on the lode. The vein matter is a hard white quartz sprinkled with spots and seams of copper and iron. The vein has widened to two and a half feet.—— The Jay Gould is being worked by two shifts of men, and cross-cutting from the 180-ft. level will commence this week. The cross-cut will expose the rich shoot of ore that has been opened at the 100-ft. level, and from which the last car of ore was shipped. Several other properties are coming to the front as producers, and will be in shape to ship steadily in the spring. —— A strike of high-grade ore was made on the Palmer Lake group recently, at a distance of 91 ft. from the tunnel portal. The vein encountered is three feet wide. The claims are owned by a company of Ohio people, and are situated on the west side of Palmer mountain, about one mile north of the Pinnacle group. The work now being done is the annual assessment work, but it is likely that on the strength of the new strike the company will proceed with permanent development. The ore encountered is a mineralized quartz, carrying both gold and copper.—— The Gold Mountain Co., which owns an antimony property in the Money Creek district, is installing machinery to treat its ores.—— The smelting plant at the property of the Galagher Mining Co., in the Clealum district, is completed, and will be blown in soon.—— The Great Excelsior Co., which owns a gold property, has ordered a cyanide plant. The mine can furnish a tonnage of ore averaging about $3 per ton. The ore is quarried out of the mountain side.——There is reported a strike of antimony ore by H. Harrett on his group of claims, 28 miles south of Kettle Falls, in Stevens county, north of Spokane. While development work is being pushed no ore will be shipped until connection is made by the Columbia River Railway & Navigation Co., with the Spokane Falls & Northern railroad to bring the product to Spokane for shipment to the reduction plants.—— The Mineral Hill Mining Co. is to resume active work on its property near Conconully. The tunnel is now in 2,000 ft., and, according to surveys, will cut the lode in 200 ft.—— T. F. Hertzell, a mining operator from the Chewelah district, reports that several properties near Chewelah are now shipping to the Northport smelter, and among them are the United Copper Mining Co.'s mine and the Copper King.——Edward A. Dolan reports a strike of gold-copper ore on the Pioneer group, 25 miles north of Conconully, Wash. The group was located 14 years ago. There is molybdenite in the vein, and the values in copper and gold are excellent—the ore running about $20 in gold per ton. The lode is 10 ft. wide, with porphyry on the hanging and slate on the foot-wall.—— The Spokane Mica Co. has received a carload of mica from its mine near Troy. It is the only shipping mica mine in the northwest. C. L. Maydwell, of Spokane, is president.

Spokane, Feb. 10.

Profit-Taking Depresses Market.—Shortage of Fuel in Siberia.—Difficulties of the Zinc Corporation.—Deep Leads Making Progress.—Cornish Mining.—Dolores Pays a Dividend.

In the mining department, as in nearly every other section of the Stock Exchange, the fortnightly account, the adjustment of which is now proceeding, is reported to be distinctly disappointing. Early in the account the bank rate was reduced to 5%; but, so far from the change having resulted in a further increase in business it was practically coincident with a sudden restriction of buying orders, with profit-taking upon a somewhat large scale and with renewed sales for the fall. The fact is all the more disappointing to Kaffir stockholders as the labor outlook in the Transvaal is certainly more hopeful than it was a few months ago, and there is a growing impression that the industry will be enabled to come to satisfactory terms with the legislative body, which is shortly to take over the reins of Government. The latest results reported by the principal Rand companies are also of a favorable character, the recent developments in the South Rand property being considered of an especially encouraging nature, not only for the company immediately concerned and for its parent (the Rand Mines) but for the neighboring deep-level mines. Other descriptions have weakened in the course of the account. A fall of 5¼ in Siberian Proprietary (from 14 to 8¾) is noted, in spite of the announcement that Prince Khilkoff, late Imperial Minister of Railways, has been elected a member of the board. Orsks have receded 1 3/16, to 1 7/16, Sesan Syndicates have lost ¾, Siberian Syndicates ½, Troitzks 5/16, and Kaneika United Goldfields 9/32. Broken Hill Proprietary has given way 1 3/32, British Broken Hill and North Broken Hill ¼, and Zinc Corporations show a drop of a shade over 3/16 at 41s. 9d., after being nearly 50s. Even the leading copper shares have shown a declining tendency, and Spassky has failed to maintain the rise in price which followed the news early in the month that the ore reserves were doubled in value, inclusive of a million sterling or more "reasonably assured." Later advices state that copper shipments were about to commence and that the smelter-fuel trouble was over. From the manager's letters recently issued to the shareholders it appears that the transportation of coal and ore has "been the burning question of the hour," and that "the collapse of the coal supply at Spassky * * * * has produced disastrous consequences," consequently "the railway must be built at all costs and quickly." This is all the more deplored seeing that both the Company's mines are in a condition to promise a large and valuable supply of mineral, and that as regards surface improvements the end may be almost considered in sight. The shortage of coal has arisen from two causes; in the first place, the flooding of the workings at the time the thaw of last spring set in, and then when the mine was unwatered in May the miners left for their homes in spite of every means employed to induce them to stay. When the miners did return in October and November the teamsters went out, so that the coal sent to grass could not be hauled to the smelter. At the moment of writing (on Christmas day) the manager was hoping for the coming of snow in sufficient quantity for regular hauling to be resumed. "It all depends upon the weather," is a sufficient indication of the importance of the railway, for which most of the material is stated to be delivered or on the road. The manager believes it is estimated that coal may be delivered to within seven *versts* of the smelter early in the coming (Siberian) spring, by which time it is hoped the bessemer furnace will be running.

To counteract rumors, which were set in motion for the purpose of 'bearing' stock in the Broken Hill section of the market, the Zinc Corporation has issued a circular to its shareholders in which the general managers in Australia flatly contradict the statement that the plant is a failure. They state that in the rush of construction an air-lift for circulation of acid liquors was put in which proved of insufficient depth, and an air-compressor proved of insufficient capacity. "Cast-iron centrifugal pumps were installed (these appliances being temporary) till proper lift and air-compressor erected. Pumps lasted only four days. During this time, while portion of the plant was running, high-grade flotation concentrates 45% zinc and 7% lead were obtained with residues of 4.4% zinc, and 1.1% lead confirming the previous work. Additional improvements are being made by erecting settling vats for re-crushed tailing, as an additiona safeguard for continuity of operation in flotation plant. Minor details require adjustment. Nothing beyond the usual experience installing large mill on a new process." The managers are confident that difficulties will be rectified in the course of a few weeks. The shares are, however, still weak on the market on fresh rumors that the plant has again broken down.

An uneasy feeling prevails as to the future of the 'deep lead' companies, and this has not been allayed by the progress report issued by Loddon Valley Goldfields. In the opinion of the market some two or more, probably three, months will be required to arrive at definite results as to the value of the deep lead in this particular property. From the report in question it appears that the tunnel at 454 ft. in depth, driven under former management, proved to be too high to get under the 'deep' ground, only the 'bench' being accessible, and it was necessary to sink the Keystone shaft and drive a new tunnel at 500 ft. in depth. This latter tunnel reached a point corresponding to that opened by the 454-ft. level, about the end of December, and is now being extended at the rate of about 40 ft. per week. By the end of January it will be one-half the way under the 'deep' ground, and has to be driven about 600 ft. farther to get entirely across under the ancient stream. In the meantime, lateral drifts are being put out, both north and south, from this tunnel, with a view to draining the wash, to effect as early an entrance into the 'deep' ground as is possible. The managers state that they are unable to indicate a definite date when work will have reached a point where it will be possible to enter the 'deep' ground, but that, at the outside, it is a matter of a few weeks.

In Cornwall the local press continues an eager discussion of the 'dues' question. It is understood that the 'lord' (Mr. Fortescue) will not sell his rights in Grenville United and Great Condurrow. With reference to the widespread rumor that Carn Brea mine has been working only under promise of a lease, J. Trevethan, the secretary, states that a lease was granted ten years ago giving the Carn Brea Co. right to work the sett under the reservations therein stated for a term of 60 years from April 13, 1896, giving, therefore, over 49 years yet to run. The lease in regard to Viscount Clifden and Tincroft sett is also completed and provides for the same terms and time as the lease granted by Mr. Basset. So far as Dolcoath and the new lords are concerned, *The Cornish Post* remarks that the hands of the clock are moving slowly. The directors, realizing that the share market was weakening, promptly countered by issuing a statement that their rights are protected by a lease which has 48½ years to run, and that at the meeting on February 28 they propose paying a two-shilling dividend,

which will absorb over £30,000 of the £100,000 cash they have in hand. They, naturally, made no allusion to the negotiations between themselves and the new lords with a view to purchasing the royalties in Dolcoath sett; but the public is still busily engaged in speculating as to what is transpiring, and what will be the result of the latest developments. Rumor has it that the first sum mentioned by Messrs. Meyerstein to Dolcoath was £200,000. If so, this must have been to 'open the ball,' as no business could be expected at this figure. From many points of view it may seem advantageous to Dolcoath to compound her future tribute to the lords for any sum up to £150,000; but there seem to be quite a number who prefer paying a possible £14,000 per year for 48½ years to parting with even £100,000 cash at one fell swoop. In the old days they clamored for big dividends, and a £5 dividend was pounced upon with exceeding great joy, although the money ought to have been spent on stone-

Eastern Australia.

breakers, Frue vanners, a new shaft, or in other ways, to strengthen the mine and enable it to cope with possible low prices, which, as a matter of unpleasant fact, began to rule almost from that time. So far as many of the shareholders are concerned, the old adage that "a bird in hand is worth two in the bush" is still regarded as worthy of all belief. A report from South Crofty for four weeks ended January 19 states that the 32 heads of stamps crushed 775 tons for 14 tons of tin and wolfram; average recovery, 40.4 lb. The excavations for the new Californian mill, 20 heads, are near completion. Tin and wolfram on hand are estimated at 37 tons.

Many new schemes are in the air for resuscitating old mines, and starting new ones, some of which it is to be feared may be found to retain their 'virgin' character as unlikely producers of the favorite metal. It is reported that operations at New Grenville, near Camborne, are being actively undertaken by the syndicate which has secured this property. Recently a new engine was installed, and is now working at the shaft being sunk on the eastern part of the ground with a view of testing this portion, where the indications are of a favorable character. The tinstone raised is highly mineralized, although the depth of shaft sunk is at this point only a few fathoms. On the north boundary, close to Wheal Grenville, an old shaft is being cleared and secured, and it is considered probable that this shaft was put down to a considerable depth. If this should prove correct, it will be a very valuable feature, as with little delay machinery could be erected, and active operations proceeded with in obtaining produce therefrom. Capt. James Rowe, of Camborne, is superintending the operations on behalf of the syndicate, which, it is understood, is about to negotiate for the disposal of the property. Some five lodes of tin and copper have already been traced within the limits of the sett, and two adit levels were driven west from the eastern boundary for a considerable distance. Some tinstuff from the 'filling' of the old north shaft assayed a high percentage of tin—from 14 to 16 lb. per ton. It is thought that this property is likely to come to the front before long, as its position, near the great deposits of metals surrounding the Carn Brea hill is among the best in Cornwall.

Another Mexican mine on the London market has entered the dividend list, Dolores Ltd. having declared a distribution to its stockholders of three per cent, payable on February 25.

Salt Lake, Utah.

New Concentrator at Bingham.— Smelter Smoke Trouble.— A Settlement Likely.— Columbus Consolidated.— Electric Power for the Cactus.—Shipments from Tintic.—Dividends.

Contracts will be let shortly for the structural material and equipment of the concentrating mill to be erected by the Ohio Copper Co. at Bingham. A site has been selected at a point near the Dalton & Lark mine. The plant will be equipped to treat 2,000 tons of ore daily, and the water supply will be obtained from the Mascotte tunnel, one of the adits of the Dalton & Lark mine, which is also to become the avenue through which Ohio ores will be brought for treatment in the future. By pushing the adit ahead 7,000 ft. more, it will not only serve as an outlet for the Ohio ore, but it will tap the low-grade copper deposits of the Commercial mine, another of the Heinze properties at Bingham. After becoming a factor in Bingham Consolidated management, Mr. Heinze acquired the Ohio, and his engineers are now directing the work of active development.

There is every indication now that the American Smelting & Refining Co. will continue to operate its lead smelter at Murray indefinitely. The manager of the plant and the smelting company's attorneys have been busy for weeks with the hope of bringing about an adjustment of the differences with the farmers. It will be remembered that the late smelter-smoke case, tried in the Federal Court before Judge John Marshall, resulted in a decree enjoining the several smelting companies in the Salt Lake valley from continuing the practice of smelting ores containing an excess of 6% sulphur on the charge, or throwing out fumes that might do damage to vegetation. For a consideration, it seems, the farmers have been persuaded to believe that conditions are not so bad as they have really been painted; for they are now willing to permit the lead smelters to operate at their old sites. Consequently, Judge Marshall will be asked to make a modification of his decree. If things come out all right and the decree is changed to suit conditions, the farmers will get $60,000; the first payment of $20,000 to be made as soon as the stipulation is properly made out and filed and $40,000 when all the plaintiffs sign a smoke easement, relieving the smelting company from being subject to further damage suits; provided, of course, that

the corporation lives up to its part of the agreement; which is to build a system of bag houses and cooling chambers into which the fumes shall be introduced for purification. A plant of this kind is now in process of installation at the big Murray plant and the smelter management sets up the claim that the system has been brought down to a point so near perfection that all deleterious substances will be removed or so modified as to be absolutely harmless.

During 1906, from the Columbus Consolidated mine at Alta was produced 6,590 tons of first-class ore, of which 6,134 tons were sold at an average of $43.33 per ton. There were mined 12,299 tons of milling ore of a gross valuation of $11.15 per ton. The receipts, including $28,646 on hand at the beginning of the year, were $432,175, while the disbursements amounted to $280,286. A total of 4,124 ft. of new development work was done; the cost of milling is given at $1.21; but no statement is given as to the expense of mining. Tony Jacobson was re-elected president and general manager at the recent

annual meeting of shareholders. It is likely that the company will join with other operators and build a standard-gauge railroad to a point within five miles of the town of Alta during the present year. The company paid its initial dividend of $45,000 in January and it has been announced that it will be paid quarterly hereafter.

The Newhouse Mines & Smelters Corporation has arranged for the purchase of electric power to be used in in its Cactus mine and mill. Although the company's properties are splendidly equipped with facilities for making power, the management is looking to the future. A repetition of the late coal famine is to be avoided. The first delivery of power is to be made at the close of next autumn.——C. A. Short, the manager for the Jenny Gold Mining Co., at Gold Springs, Iron county, has announced that the mill now under construction at that property will be ready not later than May 1.

The Eureka Railway Co. was formed a few days ago. It is a subsidiary company to the Tintic Smelting Co., which is about to construct a lead smelter in the Tintic district. The railroad will be built to several of the principal mines of the district. C. W. Nibly of Salt Lake is president of both concerns.——The ore shipments from the Tintic district last week amounted to 148 carloads, as follows: Ajax, 3; Beck Tunnel, 12; Bullion Beck, 9; Carisa, 4; Centennial Eureka, 49; Eagle & Blue Bell, 7; Eureka Hill, 2; Gemini, 5; Godiva, 1; Grand Central, 10; Mammoth, 11; May Day, 5; Ridge & Valley, 3; Scranton, 6; Swansea, 3; Tintic Iron, 8; Uncle Sam Con., 3; Victoria, 4; Yankee Con., 3 carloads.

Toronto, Canada.

Shipments From Cobalt.— A New District.— The Bureau of Mines Enriched.—The Laurentian Consolidation.—News From Cobalt.— Development of the Nipissing.— Diamond-Drilling Through the Ice.—Amalgamated Cobalt.—The Cobalt Chief.

Shipments of Cobalt ore for the week ending Jan. 26 amounted to 257 tons. The following were the shipping mines: Silver Queen, 62 tons; Nipissing, 62; University, 30; O'Brien, 30; Coniagas, 28; Cobalt Townsite, 23; Buffalo, 20 tons.

A new mining district is being opened up in the Sutton Bay country, north of Lake Temiskaming, situated in Harris township, a few miles northeast of New Liskeard. It is commonly known as the Casey Mountain range. The formation presents a similarity to that of Cobalt camp, showing the same Lower Huronian series with diabase contact. The mountain range extends for a mile and a half and has all been taken up. Native silver has been found. Two companies are already operating. The Silver Crescent Mining Co. has 15 men at work in charge of Herbert Murray, a mining engineer with a Californian experience. Several promising veins carry cobalt ore and native silver. The Bucknell Mining Co., working on an adjoining claim, employs 25 men. A shaft has been sunk 40 ft., and driving has been done for 60 ft., following a vein that contains smaltite and native silver. The company is erecting an engine and boiler house preparatory to installing a modern plant.

The revenue of the Ontario Bureau of Mines for 1906 aggregated about $250,000. This includes payments for bonuses and royalties in connection with mining grants. The receipts for the previous year were only $61,560.——The Laurentian gold mine in the Manitou Lake district, together with other mineral properties in that area, have been secured by the Hugo von Hagen Exploration Co., with $15,000,000 capital. Anthony Blum becomes general manager. This consolidation of interests is likely to result in extensive development work on the Manitou Lake properties.

As a result of the recent visit of officials and directors to the Nipissing mines, at Cobalt, a comprehensive plan for the development of the property has been mapped out, including exploration as to depth as rapidly as possible. The four shafts on veins 49, 26, 19, and 10 will be put down to 300 ft. at least. More than 800 acres of the company's holdings are as yet untouched, and as soon as spring opens this area will be prospected. The force of miners is to be largely increased.——The Cobalt Central Mines Co. has made the first ore shipment from the Big Pete mine. A drift has been started into Diabase Mtn. on the Big Pete vein at the bottom of the shaft. The ore is 26 in. wide at this point, comprising a 4-in. vein of smaltite, assaying 12,000 oz. per ton, and 22 in. of native silver running through the diabase filling of the vein. ——E. B. Rochester, managing director of the Cobalt Lake Mining Co., reports that a vein of native silver 8 to 12 in. wide has been unearthed on the east side of the right-of-way included in the company's property, assaying 975 oz. per ton. Since the beginning of operations

seven veins have been disclosed, comprising niccolite, smaltite, and cobalt bloom. A steam-drill has been in operation in two places and a shaft is being put down. Preparations are going on for diamond-drilling the southern portion of the lake bed through the ice, T. Travers being in charge of operations.——At the property of the Amalgamated Cobalt mines, near the Trethewey and Coniagas, development work is being pushed. A shaft has been sunk for 100 ft. between two veins, and on reaching the 150-ft. level a cross-cut will be run both ways. A 60-h.p. boiler, 4-drill compressor, and steam-hoist, supplied by the Rand-Jenckes Co., have been installed and 16 men are at work under A. L. Fowler, formerly a California miner. The Amalgamated is also operating on a 40-acre location north of the Silver Leaf, where a 50-ft. shaft is being put down on a promising calcite vein.——The Cobalt Chief mine, formerly known as Moore & Hare's claim, in the Portage Bay extension, has undergone considerable development during the last few weeks. A shaft and power-house have been put up and a Rand-Jenckes steam-plant installed. Two shafts are being put down, that on the main vein, now down 30 ft., being at the point of contact with a cross-vein. Some 30 men are employed, in charge of J. T. Fee, who was formerly engaged in copper mining in Michigan.

Cripple Creek, Colorado.

Active Leasing Operations.—Economic Mill Burnt.—Golden Cycle Mill Starts.—The Portland Report.—Improved Methods.

The plant of the Economic Gold Extraction Co., situated on the west slope of Squaw mountain above Eclipse gulch, was destroyed by fire on January 30. The loss is estimated at a quarter of a million dollars. Fire was first discovered in the early morning near the ore-bins and, helped by a slight breeze, soon extended to the other buildings. The mill was erected by the Wood's Investment Co. in 1899, and the chlorination process was in use, which proving unsatisfactory owing to recent advances in other methods of ore treatment, necessitated the closing down of the mill last June.——Operations have been commenced within the last few days by the Golden Cycle Co. on its mill at Colorado City. Three of the 100-ton roasters have been fired. It is estimated that there are 8,000 tons of ore bedded awaiting treatment, and that enough ore has been contracted for to keep the plant running at its maximum capacity for two years.

No better general view of the situation in this district can be gained than that afforded by a careful study of the annual report of the Portland Gold Mining Co., just issued. The conditions encountered by this company, typical in some degree of the whole district, the means by which they are met and the tabulated statements of cost here gathered together, are of the highest interest, not only to those operating in the district but to engineers in general. The folly of robbing the stopes of the higher-grade ores, trusting to lowered costs in the future to then make the removal of the lower grade profitable, has become apparent. To keep large expanses of stopes open for indefinite periods pending their final cleaning up adds materially to the final cost of extraction. To clean out stopes as they progress means handling a larger tonnage of lower grade rock. To do this and maintain profits make necessary lower costs for treatment. Hence the pressure on all departments for cheaper and better methods, and the strong probability of rather sweeping changes in the near future.

Extraction charges offer little chance for reduction. Probably three-quarters of the rock broken is hoisted to the surface at a cost of about $2.50 per ton. Nearly two-thirds of this is sorted out and thrown away, at a cost for sorting alone of nearly $1.50 on the final tonnage. The increased cost for mining on the reduced tonnage is correspondingly higher, $8.75 per ton. The charges for transportation to the mill are nearly $4, considerably more than the cost of treatment there. It is clear, then, that development must proceed along two lines; the devising of processes cheap enough to treat ores without sorting, and the moving of mills to the mines, if freight rates remain high. It seems curious to compare the relative costs of transporting a ton of ore from Duluth to Pittsburg, and from Cripple Creek to Colorado City. Of course other conditions not mentioned here help to complicate the problem, but the essential features are as sketched.

In the pressure for a cheap process, the fate of chlorination seems sealed. The cost is too high and the tailing too rich. Not long ago the sentiment of the district was strongly in favor of chlorination, now it is becoming equally strong in favor of cyanidation. Several smaller mills are going up or are already in operation at the mines; the Portland is considering the erection of a large plant at the mine. The present year is likely to witness more radical changes than any preceding one. A minor but interesting change is the substitution of a round rope for a flat one in installing the new hoist at the No. 1 shaft of the Portland. Flat ropes have prevailed in the past in spite of what seems to engineers in other districts their obvious disadvantages. But if it requires a fire to procure their removal, changes in this regard will certainly be slow.

Butte, Montana.

Shortage of Fuel Affects Output.—The Goldsmith Makes a Strike.—North Butte Extension and Its Prospects.—The Reins Copper Co.—Mining near Red Rock.—Gossip Concerning the Snowstorm.—Flynn Consolidated.—La France.

During the past six weeks all of the Butte mines have been closed from one-third to one-half of the time on account of a shortage of fuel and cars for the transportation of ore. After the thaw last week all the big mines resumed operations at nearly their full capacity, although the lack of transportation threatens a continued interruption of operations at the mines of the Boston & Montana Co. The Coalition, North Butte, and Boston & Montana companies have been the heaviest sufferers.

An excellent body of copper ore has been struck in the Goldsmith mine, the principal property of the Goldsmith Mining Co. The mine has for a number of years been a producer of silver, but during the past six months has been running into copper with increasing depth. The Goldsmith is situated some distance west and north of the Alice group of mines.——The Davis-Daly Estates Co. cut the Smokehouse lode on the 500-ft. level and is driving east and west in ore, which is increasing in value as the work progresses. It is the same vein that was cut on the 200 several years ago. In the opinion of C. H. Palmer, superintendent of the mine, the company will be hoisting and shipping ore from the Smokehouse within six months. The work of sinking on the Colorado is also progressing rapidly, and by the time the drift from the Smokehouse reaches a point immediately north of the Colorado it is expected that the shaft of the latter will have reached a depth of 1,000 ft. and cross-cutting to the same vein will have been completed.

The North Butte Extension Copper Mining Co., recently organized, is making preparations to begin development work on its properties adjoining the Berlin group of the North Butte Co. and the Blackrock mines of the Butte & Superior Co. Machinery for a complete surface

plant has been ordered and a railroad spur from the Northern Pacific is being built to the place where the shaft will be sunk. The claims of the North Butte Extension Co. are entirely undeveloped, but they are in a good territory. Immediately south of its property the North Butte is sinking on the Berlin. On the west Senator Clark is sinking on the Poser and the Butte & Superior is deepening the shaft of the Blackrock. The Blackrock and several other properties of the Butte & Superior have been producers for many years, their product being gold and silver, but the Blackrock is now being developed into a copper mine. Directly east of the Black Crow claim, on which the North Butte Extension Co. will sink its shaft, the Butte & London is sinking a shaft that is now 800 ft. deep and has cut several stringers of ore, one a vein of good size and value. Further east, on the Six O'Clock, the Butte Copper Exploration Co. has a shaft 1,000 ft. deep and is cross-cutting north and south at that depth, having cut one fine copper vein. Southwest of the Extension claims, the Boston & Montana Co. is sinking on the Badger to develop the extension of the rich Jessie vein of the North Butte Co. All the operating companies in that part of the district expect to develop rich mines, but at present the North Butte and Butte & Superior have the only developed mines of any consequence. The Blackrock vein is believed to strike through three of the Extension Co.'s claims. W. T. Van Brunt of New York has been elected president of the new company.

The Reins Copper Co. has acquired the Ella and Louise mining claims, which adjoin the Combination owned by the company, and has increased its capital stock from $1,500,000 to $3,000,000 to pay for them. The developments of the orebodies in the Combination made it desirable to own the Ella and Louise in order to protect the company's veins. J. M. Guffy of Pittsburg, the chief stockholder and financial backer of the Reins Co., took the title of the Ella and Louise in his own name and then offered to turn the properties over to the company for the increased capital stock. The offer was accepted. The par value of the stock is $1.50 and it is selling on the Butte exchange at $1.10. The increase of the capital stock was authorized at a recent special meeting of the stockholders at which 804,345 shares out of a total of 1,000,000 shares were represented and voted in favor of the increase and the purchase of the property. The company also reports that it is indebted to Colonel Guffy and associates $202,000. The company, after four years of persistent but long discouraging work, is developing a good mine and has begun taking out ore.

The Superior & Montana Mining Co. has been organized for the purpose of doing some exploration work in the Red Rock district, 21 miles west of the Oregon Short Line railroad in the southern part of Montana. The company is capitalized for 600,000 shares of stock at $5 par. Calumet, Mich., men are largely interested in the new company, and they are the same men who organized the Calumet & Montana Co. On one of the claims owned by the new company there is a shaft 100 ft. deep and the showing is said to be good, a vein 2½ ft. wide assaying from 7 to 19% copper, with some gold and silver. The company owns seven full claims and expects to begin development work on them about the middle of February, if the weather permits. An air compressor and other machinery is expected to be delivered by that time.

The report is again out that F. A. Heinze of Butte is negotiating for the purchase of the Snowstorm mine at Mullan, Idaho, but when Mr. Heinze examined the property several months ago he said he did not want it. The only thing that has ever thrown discredit on the Snowstorm has been the eagerness of the present owners to sell the property, which has been peddled among all the big companies and copper men in the country. Among those who have recently had the mine examined for them are the Lewisohns.——It is reported that the directors of the Ida-Montana Development Co. are considering the advisability of re-organizing. The company is developing some claims in the southeastern portion of the Butte district and the showing is considered good enough to warrant the organization of a mining company. The exchange basis is to be about three shares of the new company for one of the old.——There is a possibility of the organization of a new company to take in the Granite Mountain mining claim owned by the Lewisohns, and the Tuolumne claim owned by the Tuolumne Mining Co. The Lewisohns are engaged in sinking a deep shaft on the Granite Mountain, and some extensive and rapid development work is being done on the Tuolumne. Both claims are well situated, the Tuolumne adjoining the Speculator mine and the Granite Mountain being next to the Jessie mine of the North Butte Co.

The Flynn Consolidated Mining Co., which owns a lot of mining claims near Hailey, Idaho, is about to begin development work on its properties. The company has been financed by Butte and New York men and at a recent meeting of the directors George W. Munroe, of New York, was elected president, and C. W. Andrews, secretary.——La France Copper Co. is placing the Lexington mines in condition for a large increase in the ore output, and in six months the daily output is expected to reach 300 tons. The mine for many years was filled with water and it required a year's work to pump the mine dry. The lower workings are now being cleaned up and repaired. The mine is about 1,500 ft. deep. La France Co. has been mining on the upper levels for more than a year and is making regular shipments of good ore.

Denver, Colorado.

Development in Depth at Cripple Creek.—Reduction of Treatment Charges.—Competition Between Cyanidation and Chlorination.—New Mills.—Good Prospects for Current Year.—Transfers of Property.—Drainage Adit.—Promising Outlook.

Cripple Creek is now at a most interesting stage in the history of its development. In fifteen years it has produced 221 million dollars in gold. It was not strange, therefore, that a few years ago certain timorous ones began to suggest that possibly the ore deposits were in danger of becoming impoverished in depth, and that perhaps the beginning of the end of this great district could be dimly discerned. These fears were laid to rest by the publication of the admirable report of the geological investigation conducted under the joint auspices of the State of Colorado and the United States Geological Survey by Messrs. Lindgren and Ransome. It was there pointed out that surface enrichment could not be observed in the veins; and, therefore, so far as logical inference goes, the veins may well hold their values indefinitely, if they themselves persist in depth.

But other factors also affect the production of a mining camp. With the 16% reduction in the output for 1906, compared with that of 1905, has come a corresponding pressure for the reduction of treatment charges. Cyanidation has locked horns with chlorination in what promises to be a death struggle and all who are interested are anxiously awaiting the outcome. The United States Smelting & Reduction Co., which has been chlorinating by the electrolytic process, concentrating and cyaniding its tailing, is said to be seriously considering abandoning the barrel room The Portland Gold Mining Co. is just completing a 400-ton plant for fine grinding in cyanide solution in tube-mills to treat the tailing that has been accumulating from its chlorination plant. This plant is supposed to

contain $2.50 per ton, hence a handsome profit is expected. One tube-mill is lined with silex blocks and it is planned to line the other with cast-iron liners, which will furnish a useful comparison. The Golden Cycle mill is now in operation and is offering to treat ores for $3 per ton less than the rate heretofore asked. This reduction has been met by the smelting companies, which means a correspondingly great saving to the mines which do not possess reduction works. The process at the Golden Cycle is, after roasting, to catch the coarse gold by amalgamation and then to cyanide. The outcome is awaited with interest, for much skepticism is rife as to whether the loss of mercury can be kept so low as not to effect the cyanidation unfavorably. The Gillett cyanide mill has been purchased by the new management of the Jo Dandy and is being removed to that property. It is also said that Stratton's Independence, Ltd., is planning the erection of a cyanide mill. Altogether, it seems as though cyanidation were destined soon to triumph. Bromocyanidation will now have a fair chance, and it would not be strange if it were to make a better showing than it has in previous trials.

With the lowered costs has come a correspondlng activity in mining transactions, and the prospects seem bright for a marked increase in production during the present year. The Trilby and Ben Harrison claims on Bull Hill have been purchased by Markle, Montgomery & Conning from the Moose Mining Co. The Delmonico, and a portion of the Maud Helena on Bull Hill, have also been purchased from the Union Gold Mining Co. by I. W. Duner, and associates. The claims last mentioned form a portion of the Stratton estate, and the transfer is interpreted to mean that the executors are disposed to segregate its vast acreage into small holdings. The control of the United Gold Mines Co. has passed into the hands of J. T. Milliken, president of the Golden Cycle. This involves over 400 acres of some of the best property in the district. With the change in management has come a reduction in royalties, and more than fifty lessees are now at work.

With the announcement of the intention of the mine owners to begin driving the deep drainage adit another note of encouragement is sounded. This adit is to have its portal in Gatch Park at an elevation of 8,020 ft., or 753 ft. lower than El Paso, the lowest of existing adits, and will go far to solving the water problem. It is expected to drive it to the main water course—a distance of 15,550 ft.—in two years. It is then planned to continue it to the Vindicator shaft, giving a total length of 27,190 ft. This distance is to be driven in five and a half years, at a cost of $721,000. The mine owners are, wisely enough, raising a fund of $1,000,000 for this purpose. D. W. Brunton is the consulting engineer, and, if his recommendations are carried out, the adit will be 7 ft. wide by 10 ft. high, and have a grade of one foot in 300. The heading is to be driven in both directions from a shaft 10,000 ft. from the portal and diamond-drills are to be used to hasten the work. Ventilation will be obtained by the use of positive blowers. In the light of these improvements, present and prospective, the future of the district seems most promising.

Calumet, Michigan.

Storms Block Ore Shipments.—Exploratory Operations.—Strike Ended at the Mass.—Atlantic Cuts Lode on Section 16.

The January production of the Lake Superior copper district was curtailed considerably because of severe storms that blocked the railroads and prevented regular shipments of ore from the mines to the stamp-mills. In Ontonagon county the Michigan and Mass Consolidated mines suffered especially. Snow blocked the branch of the Mineral Range road leading to the Michigan and prevented any shipments being forwarded to the Atlantic mill, where two heads are under lease, for several days. In Keweenaw county the Mohawk and Allouez also suffered from the storms. The Wolverine and Centennial mines, in Houghton county, lost a few days' production, owing to the same cause. Other mines suffered to a less extent. Diamond-drill work from surface has been resumed at the Rhode Island property and the Kearsarge amygdaloid formation will be more thoroughly explored. The Rhode Island has had two drills in operation underground for some time. At the Tecumseh property, which is now part of La Salle and controlled by the Calumet & Hecla company, development work is being pushed steadily. Shipments are being made to the Franklin mill. The showing underground continues excellent and drift-stopes are being extended on the three bottom levels. There has been no change in the local management of the Tecumseh as yet, R. M. Edwards of Houghton continuing as superintendent. Notices have been issued of the annual meeting of the Keweenaw Copper Co., which will be held at New York on February 12. Charles A. Wright of Hancock is president and Captain Thos. Hoatson of Laurium is general manager. The Kewee-

naw Central railroad is now operating passenger and freight trains between Calumet and its northern terminus, Mandan, the trains being run over the tracks of the Mineral Range south of the Mohawk mine.

At the Atlantic company's exploratory shaft on Section 16, a vein carrying some copper has been encountered. It is too early to state positively whether the formation is the Baltic or some other lode, but it has some of the characteristics of the Baltic.——After an idleness of twenty days, caused by some of the employees striking for higher wages, work has been resumed at the Mass Consolidated mine in Ontonagon county. A special meeting of the directors was held at Boston, the superintendent, James M. Wilcox, and the president, Charles A. Lamb, going east to attend. It was decided to offer the miners an increase of ten cents per day, or $2.35, the same as is paid at the Michigan mine, and the trammers $2.07, the same as before the strike. The men decided to accept these terms. The strike at the Mass mine was free from disorder and the best of feeling prevails between the workingmen and the mine management.——C. R. Forbes, engineer at the Michigan mine, Ontonagon county, resigned a short time ago to accept a more responsible position in the Tonopah district, Nevada.——Development work at the Franklin Junior portion of the Franklin mine is going forward steadily. There is a steady improvement in the openings and the bottom levels are looking well. No. 2 shaft and rock-house will be completed shortly and as soon as the equipment is fully installed, the production at that point will be increased.

Victoria, British Columbia.

Mining in the North. — Prospects on Knight's Island. — Prince William Sound. — The Tyee. — Explorations on Vancouver Island.

This is the season of the year when the prospectors and owners of mining properties in Alaska and the British Yukon gather at Seattle, Vancouver, and Victoria to take a holiday and at the same time bring their properties to the notice of the representatives of capitalists, many of whom reside in the Coast cities and are prepared to take bonds on properties in the North. Most of the Northern men arrive with samples of ore, maps, and in some instances reports made by mining engineers and certificates showing smelter returns. It is the season when the daily newspapers are filled with interviews given by the Alaskans and Klondikers in which the attractions, accessibility, and general information relative to the Northern camps are fully described and consequently the general public rather naturally consider that they know something about the Far North and are competent to form judgment and make investments in mining propositions brought before their attention. The present winter, owing largely to the high price of copper, has been an exceptionally good season for the owners of mineral claims to negotiate bonds and in some instances receive cash payments for their properties.

The most fashionable locality just at present is Knight's island on Prince William sound, where a large number of locations were staked during last summer and early autumn. This island being situated on the sound between La Touche island and that portion of the mainland where the Ellamar mines are situated, is receiving much attention, because the prospective seller can so easily produce his map and show that the mineralized zone traverses the island. It is a fact, however, that a large number of outcrops of chalcopyrite have been discovered, many of which promise to develop into copper mines of value, but up to the present time the development work performed has been quite limited in extent and about the best that can be said is that many of the prospects possess great possibilities. There is no doubt but that during the coming season really earnest attempts at development will be made on several locations not only on Knight's island, but also in other parts of the Prince William sound district.

Although up to the present time only two mines have been regular shippers, namely, the Robertson-Beatson mine on La Touche island and the Ellamar mine on the mainland, about 26 miles southeast of Valdez, yet there are many promising prospects on Galena and Landlock bays near the Ellamar, also several on La Touche island. In fact, there is apparently a mineralized zone extending practically the entire length of this island, and during the summer of 1906 there were six properties being worked in addition to the Robertson-Beatson.

All of the copper camps in the Prince William sound district are comparatively new. The first location, the Ellamar, was staked in 1897 and a little later the Robertson-Beatson property was located. The high grade of the ore and the great showing, especially on the later location, soon attracted experienced prospectors to the district. That portion surrounding Copper Mtn., which is a prominent landmark a short distance from the Ellamar mine, and which can be approached on three sides by water, was especially favored and was soon covered by location stakes. Several reasons, of which lack of capital was the foremost, combined to retard development so that until last year such work had been practically limited to the annual assessment, but during 1906 more earnest effort was put forth, especially by W. A. Dickey; Steel & Burke; Ryer & McDonald; Putz, Steinmetz & Eagan; the Reynolds Alaskan Development Co., and B. F. Mailard, all of whom were ambitious to place their properties in the ranks of shipping mines. Mr. Dickey made some shipments from Landlock bay, but, owing to litigation, he was not able to push work as fast as he desired.

To jump from Prince William sound southeasterly to Vancouver island is a long distance, but, when I started this communication, I did not intend to go so far afield but rather to confine myself to that portion of British Columbia where very many good prospects have been located since 1898 and some copper mines successfully operated, especially the Tyee on Mt. Sicker. This company has smelted nearly 200,000 tons of ore taken from the Tyee mine in its smelter at Ladysmith; and during the present year, in addition to smelting ore from that mine, the company will be treating the same character of ore from the Richard III, which adjoins the Tyee on the east, and which, after lying idle for about three years, is again being actively operated.

Just at present only two copper mines on the island are working, but during the fall of 1906 the property known as the Black Prince group on Sidney inlet, on the west coast, was bonded by the owner, Edgar Dewdney, to the Alaska & Northwestern Copper Co., of Seattle, which will prosecute development vigorously. There is also a good prospect that the property owned by Thompson, Tolmie & Donaldson at East Sooke, on which there is an excellent showing of chalcopyrite ore of good grade, will be bonded to responsible parties in the near future, when operations will be again resumed. There were some 400 tons of ore mined from this property from an open-cut about four years ago, all of which remains on the dump, notwithstanding that it only requires three-quarters of a mile of surface tramway to connect the mine with deep water at Sooke harbor and that the ore will probably average about 10% copper. The owners have preferred to have the ore on the dump, at any rate until the mine was sold.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

ZINC is generally determined quantitatively in the laboratory by titration with potassium ferrocyanide, using uranium nitrate as an indicator.

TUFA is a cellular deposit of mineral springs, usually calcareous or silicious. The name is not to be confused with tuff, which is the name given to the finer, fragmental ejectments from the explosive eruptions of volcanoes.

JAMES J. HILL recently claimed that the passing of 44 trains per day over the tracks of the Great Northern Railroad constituted a record. It is a fact, however, that during the Comstock boom the Virginia & Truckee Railroad carried as many as 46 trains per day to Reno.

ALUM-SHALES are shales charged with alum, which in favorable localities may be commercially leached out and crystallized. The alum results from the decomposition of pyrite, the sulphuric acid thus produced reacts on the alumina present, yielding the double sulphate, which is alum.

GLASS is considerably stronger than granite, except in the matter of crushing, in which they are about equal. The tensile strength of glass is from 2,500 to 9,000 lb., the crushing strength 6,000 to 10,000 lb. per sq. in., and a piece one inch square, and one foot between end supports, breaks under a centre-load of about 170 pounds.

THE electrolytic method for the determination of copper is the one most commonly used now by the smelters and large copper companies. The crucible method is still in use for high-grade concentrate. The colorimetric method is an easy and rapid way for approximate results, especially on low-grade material. The cyanide method is a good one, and is much used, it consisting in obtaining the copper in a blue ammoniacal solution, and then estimating the amount from the quantity of standard solution of potassium cyanide required to destroy the blue color. The titration with sodium thiosulphate is recommended as an accurate method, this process being known as the iodide method, and said to be more practical than, and nearly as accurate as, the electrolytic method.

AMYGDALOIDS are cellular lavas, whose cavities, caused by expanding steam bubbles, resemble an almond in size and shape. The name is derived from the Greek word for almond. Basaltic rocks are most apt to develope these cavities. The term is used in the form of the adjective, amygdaloidal, and properly should be limited to this. As a noun it is employed for secondary fillings of the cavities, which are usually calcite, quartz, or some member of the zeolite group. Amydaloidal rocks are of chief interest on the Keweenaw peninsula, Lake Superior, where certain basaltic lava sheets have their amygdules filled with native copper and are important sources of the metal. Amygdaloidal cavities are often limited to the upper and lower portions of the lava sheets.

SODIUM AMALGAM is used to some extent in mills. It will decompose the salts of the metals, forming an amalgam of the metal and mercury. To make sodium amalgam, clean dry mercury is heated gently, and pieces of sodium about the size of a pea are added slowly, until a soft, putty-like product is obtained. It should be kept dry and away from the air, preferably under naptha. This amalgam has a powerful reducing action, reducing metallic salts to the metal, and thus eliminating these causes of flouring. It is fed into the battery with the mercury, but as it causes the base metals that have been reduced from their salts, to go into the mercury, it often does as much harm as good, and is not in general use. Metallic sodium may be purchased from any standard dealer in chemical supplies.

AS TO the question of removing water from a shaft with a syphon, where plenty of fall is to be had, it could be done, provided the shaft were not too deep. The theoretical height of the water-column that the air-pressure will sustain is about 33 ft., but practically it is only about 28 ft., varying, of course, with the altitude. The diameter of the hose or pipe is immaterial, but the flow will continue only until the level is reduced to the height of the highest end of the syphon, and only when the vertical height from the highest part of the syphon to the lowest level to which the reservoir may be drawn does not exceed 28 ft., which would only admit of lowering the water eight feet more in the case cited by our correspondent, where the water is within 20 ft. of the collar of the shaft.

IN reply to the question of cleaning mercury, impurities may be removed by distillation, which, however, does not always eliminate the most volatile foreign metals, such as lead and zinc. It is best to distill at a low temperature, in a current of superheated steam, in order that globules of the impurities may not be carried over with the mercury vapor. The most general plan is to purify by treatment with dilute nitric acid, allowing it to digest for 24 hours. One part of acid to three of water is the best proportion. It is a good plan to keep mercury, after treatment of this kind, in a glass or earthenware vessel, under a layer of weak potassium cyanide or dilute nitric acid, and draw it off when needed, through a cock in the bottom, and wash with water before using. The principal impurities are the base metals, such as lead, copper, iron, zinc, bismuth, arsenic, and antimony. Impure mercury is recognized by the fact that it leaves a tail behind it in flowing down a glass plate in pear-shaped globules, and it will leave a film on rough blotting paper.

IN reply to the question: Is a placer location good located 1,500 ft. by 600 ft. on surveyed land, when local custom has been to locate on legal sub-divisions of 20 acres to one man, and 160 acres to a company of eight names?

The answer is as follows: There is no law in California requiring either the posting or recording of a notice of location, consequently no rule by which the validity of a notice can be tested except by applying general principles announced by the Land Department or the Courts of States having laws regulating the subject.

The later rulings of the Department of the Interior uniformly reject the notice of a placer location on surveyed lands which does not describe some legal sub-division of the public surveys. A description by metes and bounds not conforming to the rectangular legal sub-divisions would be rejected, as the basis of an application for patent. This rule has at times been relaxed where the claim lies in the bed of a stream or gorge with precipitous cliffs for its sides, which are practically inaccessible, for example, the Grand Canon of the Colorado River. But otherwise it is rigidly enforced. The Supreme Court of California has on one occasion, at least, given to the law a somewhat more liberal construction (142 Cal. 404). But even applying such liberal rule, the notice in question falls short of the requirements as the basis of a patent application, or of a record, if such record is authorized by local rule or custom.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Dredging in Montana.

The Editor:

Sir—In a communication from Mr. C. W. Purington, in your issue of July 28, 1906, is the statement: "In the United States proper, with the exception of the operations already noted in California, the public knows of no profitable gold dredging, from authenticated published statements, although in Montana, Idaho, Arizona, and Colorado dredging operations have been attempted, and there are rumors that some dredges have been made to pay."

As to "authenticated published statements" I cannot speak, but it is a well-known fact that the first successful placer dredges operated in the United States were at Bannack, Montana, and that the present operations of the Conrey Dredging Co. at the lower end of Alder gulch, near Ruby, Montana, are attended with good profits, although no figures can be obtained, the concern being a close corporation.

ALEXANDER LEGGAT.

Butte, January 23.

Mr. Lamb and the Butters Filter.

The Editor:

Sir.—In a recent number of the PRESS*, Mr. Mark R. Lamb, of the Butters Co., has criticised a comparison I made† of the Moore and Butters filters as applied to conditions at the Liberty Bell mill. Mr. Lamb claims that my comparison was unjust and unfair to the Butters process, and goes on to say that instead of the one I made, a comparison with the Butters installation for the Tonopah Mining Co. at Millers, Nevada, would be in order.

Since reading Mr. Lamb's article I have obtained additional information covering the points raised, and in the light of that information I am forced to doubt Mr. Lamb's data and question his conclusions. Mr. Lamb does not state specifically that all of his data are from the plant at Millers, but, as that plant is one of the latest of the Butters installations, it presumably represents the best Butters practice, and it would seem fair to examine Mr. Lamb's statements and conclusions in the light of facts pertaining to that plant.

Mr. R. Chester Turner, superintendent for the Tonopah company, and Mr. A. R. Parsons, mill superintendent, have kindly furnished me information about the Millers plant, which is given below in parallel column with Mr. Lamb's statements:

	Lamb.	Turner & Parsons.
Capacity of filtering vats	Not given	9,130 cu. ft.
Size of filters	5 by 10 ft.‡	4 ft. 9 in. by 9 ft. 9 in.
Number of filters	216	192
Time required to transfer pulp	10 minutes	20 minutes
Time required to fill vats with water	10 "	20 "
Discharging cake	10 "	Not given
Running back water	Not given	20 minutes
Running in pulp	10 minutes	20 "
Maximum height of lift during transfer of pulp and water, by centrifugal pumps	10 feet	25 feet

It would have seemed in order for Mr. Lamb to have made sure of his own ground before attacking the statements I made.

In a personal letter he admits the fairness of my assumption, that, with the same slime, the loading and washing periods and the vacuum required, etc., can be figured the same for both processes. Let it be assumed then that Liberty Bell slime is to be handled by a plant built of the same units as at Millers. The treatment cycle would be as follows:

Loading	60 minutes
Running out pulp	20 "
Running in water	20 "
Washing cake	60 "
Discharging	15 "
Running out water	20 "
Running in pulp	20 "
Total	215 minutes
Total time of cycle	3 hr. 35 min.
Total number of cycles	6.7 per 24 hr.

Mr. Lamb states that 250 leaves or filters like the ones installed at Millers "would easily handle the mill output (Liberty Bell) of 350 tons per day." As stated in my previous article, 45 changes of the Moore baskets are now necessary to handle that tonnage. Each basket has 66 filters 6 by 8 ft., giving a filtering area of 6,336 sq. ft. per basket. With 45 charges, then, we would have 285,000 sq. ft. of cake formed. The 6.7 cycles of the Butters unit, under consideration, would represent 59,563 sq. ft. of cake formed, as the 96 filters have an area of 8,890 sq. ft. To handle, then, the Liberty Bell tonnage would require 4.79 vats of the size at Millers, or 460 leaves instead of the 250 that Mr. Lamb gives as a sufficient number, or the 330 Moore leaves now doing the work.

Again, Mr. Lamb states that one properly designed box for 250 Butters leaves will contain approximately 7,000 cu. ft. If this is so, why were not the Millers boxes properly designed? The two contain only 192 leaves and have a capacity of 9,130 cu. ft. These two boxes have an aggregate filtering surface of 17,780 sq. ft., which gives 0.51 cu. ft. of box per square foot of filter. The Moore boxes at the Liberty Bell have a capacity of 3,050 cu. ft. each, as stated in a previous article, and one basket has 6,336 sq. ft. of filter surface. This gives 0.48 cu. ft. of box per square foot of filter. It would seem from this that the Moore boxes at the Liberty Bell are rather better designed for Butters process work than are the boxes installed by Butters; and Mr. Lamb's contention that "it is certainly not fair to require the handling of the large quantity (of slime) needed to fill (the Liberty Bell) filter vats, which are not designed as in the Butters filter-box, to contain barely enough slime to cover the leaves," rather falls to the ground. These boxes are of the same general design, that is, they are rectangular boxes with hopper-bottoms, having a 60° slope.

Mr. Lamb advocates the use of one large filter-box for the Liberty Bell, instead of the units at present in use for the Moore process, and says that one 9-in. pump would probably handle the pulp in 10 minutes. For a box containing 250 Butters leaves, the capacity would be 11,800 cu. ft., if it were of the same design as the boxes at Millers, instead of the 7,000 cu. ft. given by Mr. Lamb. The amount of pulp and water to move would be about 1,900 cu. ft. less on account of the displacement of the loaded filters, giving 9,900 cu. ft. of material to handle. If we accept the statements of pump manufacturers—and the capacities of their pumps are probably not underestimated—a 15-in. discharge pump would be necessary to move this volume of material in ten minutes, or a 12-in. pump in 20 minutes. If we put our 460 leaves in one box, a 15-in. pump would be necessary for moving the pulp in 20 minutes, and a 20-in. pump necessary to do it in 10 minutes.

His proposition to use a single large vat also involves the condition of maximum power consumption where power is bought on peak load.

Mr. Lamb's statement that "as 48-in. pumps are regularly used to transfer sand in dredging, it is hardly in order to call a 9-in. pump 'large' or to consider it or its valves difficult of operation," scarcely calls for comment.

*MINING AND SCIENTIFIC PRESS, January 12, 1907, page 54.
†MINING AND SCIENTIFIC PRESS, December 15, 1906, page 714.
‡Given in personal letter to me.

It is safe to say that where a 48-in. pump is regularly used for dredging sand, it is not used in connection with a nest of 48-in. valves.

Mr. Lamb asks why a gravity plant could not be placed at the Liberty Bell. The answer is, for the same reason probably that it was not installed at Millers. It would cost more to excavate for it than it would be worth.

In a personal letter, Mr. F. L. Bosqui has pointed out wherein my former article was seriously incomplete, by not giving comparative cost data for filter-repairs and maintenance, for the Butters and Moore systems. Mr. Bosqui's criticism is entirely just. I could not give these data, as I have not got them. Such as I have on the Moore process, are vitiated by two factors, namely: At Bodie, the plant was run several weeks without regrinding, and the heavy sand rapidly cut the filters to pieces, and raised the costs materially for the period covered by the data I have. At the Liberty Bell, the filters are being changed as rapidly as may be to a better type, in part similar to the ones at Bodie, and repairs make consequently a large item. Experience seems to indicate, though, that filter-repairs are less for the Butters than for the Moore process.

EDWARD H. NUTTER.

Telluride, January 30.

The Production of Copper.

The Editor:

Sir—In reference to your editorial remarks concerning the failure of the Lake Superior copper mines consolidation and your restrictions on the operations of Messrs. Cole and Ryan, may I suggest that there is one view of the question that possibly has escaped you.

The world's known supply of copper is, and has been for many years, limited and today there is no great expectation of huge discoveries to be made. The supply of copper, either native or as an ore, is not, like iron, relatively unlimited and dependent only on the size of the reduction works for its output. And yet in no industry has so foolish a policy been followed for the last thirty years as in the production of copper. When the price went down, owing to decreased demand, every company strained itself to the utmost to increase its production so that its net earnings might remain the same, this only accentuating the difficulty and still further depressing the price, till we had the spectacle of a metal costing nine cents per pound to produce selling for 11 cents. On the rebound we have copper selling at 25c. per pound, a price which both producer and consumer agree is too high, and yet it has been forced upon the community by the extravagent production of the metal in the past five years.

Can anyone uphold the action of Col. W. C. Greene in his riotous output of copper from Cananea without profit to his company in the early days of that camp, when silicious ores were smelted with coke transported by wagon from the United States instead of being kept in reserve until ready for concentration by water after rail communication had been established? Does anyone uphold the carnival of crime and debauchery rampant in Butte for ten years during the Heinze regime? Yet this last blot was removed by Messrs. Cole and Ryan, and in their taking hold of the Greene and placing Mr. L. D. Ricketts in charge, that property may at last be put in such shape as to pay dividends to its stockholders and not be the mere football of interested parties.

Although I have said that iron is unlimited, even that is but a relative term, and the closer association of iron producers in the United States in the last five years has given a steadiness to the trade and a production more nearly dependent on the consumption. In copper we have had a consumption dependent on production and I believe that a better understanding among copper producers of the conditions of the market and the elimination of petty jealousies by centralization of control will do wonders toward establishing a steady price for that metal, not as low as 11c. nor as high as 25 cents.

If Messrs. Cole and Ryan can accomplish this result, they will receive the thanks of the industry and they are welcome to whatever they can personally make in the steadying of values of copper and copper mining stocks.

OSSIPEE.

New York, February 8.

Modern Gold Milling.

In the modern plants a good deal of attention is being paid to securing good and substantial foundations for the apparatus, and especially the stamp batteries. Liberal use is made of concrete for this purpose, and the foundation work is sometimes very costly, but the increase in cost is more than made up for by the solidity and freedom from jarring and vibration of the building. In regard to the battery foundations, modern tendencies are overwhelmingly in favor of the concrete foundation. The prejudice which unquestionably existed in the mind of many managers, even men of wide experience in stamp-mill practice, against the concrete foundations, seems to be fast disappearing.

It is quite true that the opponents of the concrete foundation could point to instances where the foundations had not given satisfaction, but the greater part of the trouble was undoubtedly caused by the unfamiliarity of the men who built the foundation, with the kind of material required for this work, and perhaps their unfamiliarity with concrete work in general. It is not always easy in far-away mining regions to secure men particularly fitted for carrying out a delicate job of work which requires care and attention, as concrete work undoubtedly does, and the tendencies to carelessness in the working of the material and the proper mixing and proportioning of the ingredients are always present. Moreover, a good deal of care is required in getting the battery mortars to bear evenly with their lower surface on the top of the concrete foundation.

The interposition of a sheet of rubber to cushion the blow is, of course, an additional safeguard in this respect, but it is much more advisable to pay careful attention to the leveling of the top of the foundation and to use a comparatively thin sheet of rubber than to rely upon a thicker intervening layer. A well-built concrete foundation is sure to last indefinitely, and to cause much less trouble than a wooden foundation, which latter is undoubtedly the weakest point in the battery, and a source of considerable trouble when it needs repairs and renewals.

A point to which particular attention should be paid in the construction of concrete foundations is that the proper amount of cement should be allowed in the mixture. This is one of the instances where it does not pay to save on the cement and use too high a proportion of inert materials. It should always be remembered that the cement is the only material that holds the concrete together and gives strength to the mixture, and that a structure which is so much subjected to vibration and strains as a battery foundation is, needs to have considerable strength. The tendency, of course, to cheapen the cost of the concrete by decreasing the amount of cement is always present, especially when the work is done by independent contractors. One instance of such a procedure came to the notice of the writer, where the battery foundation had cracked on account of the poor material used by the contractor, and had to be largely replaced.— George P. Scholl in *Electrochemical and Metallurgical Industry.*

A Question of Mining Law.

As usual at the beginning of the year, in any gathering of mining men there is apt to be some kind of an argument regarding the mining laws as they affect the rights of one location over another. The editor of this journal is sometimes asked to decide the controversy. A recent inquiry is stated thus:

A locates a mining claim in June, 1905, claiming 750 ft. easterly and 750 ft. westerly, does his location work, and records; but in the year 1906 he fails to do his $100 worth of work, and virtually abandons his claim. In August, 1905, *B* locates a claim as marked in dotted lines, and claims 200 ft. easterly and 1,300 ft. westerly. He does his location work, and records, and in 1906 does his necessary $100 worth of work. Does that portion of *A*'s claim become *B*'s ground when *A*'s claim reverts to the Government on the night of December 31, or if *C* should come along and re-locate *A*'s claim, would he be entitled to all that *A* had formerly owned? Some assert that *B* never had any right to claim 1,300 ft. of *A*'s ground originally, and would have to make an amended location to get that ground, which in this case would make him put up his amendment on the night of December 31, as at that time *C* was going to re-locate *A*'s claim. Others argue that if *B*'s claim ran in an opposite direc-

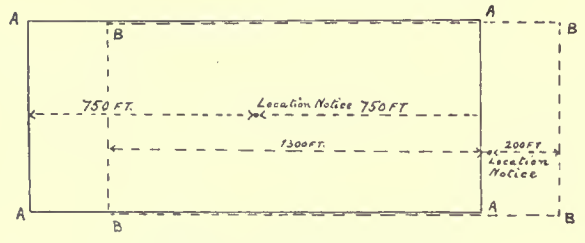

Diagram of Conflicting Locations.

tion and ran into *A*'s side lines, instead of his end lines, that upon *A*'s claim reverting to the Government, it would belong to *B*.

The question raised by this inquiry is one of the most important arising under the mining laws, as well as the most difficult to answer. It embarrasses the bench and bar alike and involves in its consideration problems which the press, lay, scientific, or technical, should not attempt dogmatically to solve. We may be permitted, however, to present briefly the state of the decisions and in a tentative way suggest certain deductions.

The Supreme Court of the United States in Belk *v.* Meagher, 104 U. S. 279 (1881), held in terms that a location can only be made where the law allows it to be done; that any attempt to go beyond that will be of no avail. Hence a re-location on lands actually covered at the time by another valid subsisting location is void, and this not only against the prior locator, but all the world, because the law allows no such thing to be done.

For many years, and by an unbroken line of decisions the courts of the mining States, both State and Federal, held that under this decision of the highest Federal tribunal a junior location which overlapped a valid subsisting senior claim was absolutely void as to the conflicting surface area, and that the only method by which the junior locator could acquire such surface upon abandonment by the senior was to amend his location, after such abandonment, and include the abandoned area, or to state it in the form of a postulate; where a junior location conflicts with a senior, the conflicting area did not, on abandonment of the senior location, enure by gravity to the benefit of the junior.

However, in the later case of Lavagnino *v.* Uhlig, 198 U. S. 443 (1905), without a reference to or a comment upon its earlier decision in the Belk-Meagher case, the United States Supreme Court announced what appears to be a doctrine diametrically opposed to the old rule. This later expression of views of that tribunal may be stated as follows:

"Upon the forfeiture of the senior location prior to the junior locator's application for patent the conflict area enures to the benefit of the junior locator, and one who locates the senior claim after it has become subject to forfeiture cannot successfully adverse the junior locator's application for patent."

This quotation is taken from an excellent dissertation on this subject in a note to the case of Wilson *v.* Freeman, Book 68 L. R. A., p. 843.

The Supreme Court of Idaho sums up the situation as follows:

"It has been generally understood throughout the mining States that Belk *v.* Meagher had become the settled law, to the effect that no valid re-location can be made on a mining claim until the rights of the former locator have been finally forfeited or abandoned, and that a location made after the forfeiture or abandonment would take precedence over such invalid re-location; but Lavagnino *v.* Uhlig, decided less than a year ago, appears to have been entirely upset by that doctrine, and it will be a matter of great interest to lawyers and courts, as well as the miners of these Western States to know just whether these cases are distinguishable on principle or the one overrules the other entirely."

Ambergris Min. Co. *v.* Day, 85 Pac., p. 114.

The mining lawyers of the West are practically unanimous in the view that the later expression of the Supreme Court of the United States is wrong in principle, and based upon erroneous or fallacious reasoning. An able statement of the prevailing dissent from the later revelation will be found in an elaborate note in Book 68, L. R. A., p. 843, heretofore referred to.

To recur now to the inquiry of our subscriber. If we assume that the later decision must be construed as a practical reversal of the former, and that the two cases cannot be distinguished or differentiated, we may deduce the following reply:

If in the case as stated in the inquiry, *B*'s discovery is on free ground, the conflict area will fall by gravity to *B*, without any affirmative action on his part, as soon as *A* abandons his claim or fails to perform his annual work; *C*'s location would be void as against *B*. If *B*'s discovery should be within the conflict area, *B*'s location would be void and *C*'s would prevail.

On every mine where drills are extensively used, a fitting shop, or a large section of one, will be set aside for their upkeep and maintenance. It will be found a good plan to have each machine brought up once a month, that it may be thoroughly cleaned and wear taken up before it increases. Most of the wear, especially on exposed parts, such as the feed screw and nut, is due to the mixture of grit and grease in which these parts work; unless this is cleaned off at frequent intervals, both the life and efficiency of the machine are impaired. The simplest plan, and one saving considerable labor, is to place the dismantled parts in a vat of soda solution, kept at boiling point by a steam jet, or other means.

The features desirable in a rock-drill are reliability, dead blow, variable stroke, portability, compactness, protection, and interchangeability of working parts, and provision for taking up wear. Most machines combine these points to a certain extent, while no drill excels in all of them.

Cornish Tin Mining.—II.

Written for the MINING AND SCIENTIFIC PRESS
By H. E. WEST.

The Cornishman has been a miner from time immemorial and he is to be found following his calling wherever mines are being worked. The labor available in Cornwall today is barely adequate for present requirements and quite insufficient for any wholesale re-opening of the old mines. Doubtless, many miners will be tempted to return, especially as the price of labor is likely to increase. A miner working full time for the month works but 24 shifts of eight hours. Of course, the mines are somewhat deep and bad ventilation must also be considered. In the Western States, however, a miner calculates to work every day in the month, and, as often as not, longer than eight hours, his remuneration being usually $3.50 per shift. Labor is divided into contract and day labor, the former being again subdivided into two classes, 'tributers,' or 'tut-work' men, and 'owner's account men,' as day's-pay men are termed.

In Cornwall, miners underground do not usually work too hard; in fact, for actual honest work done, the shift is below the average, taking miners at large; and, in the contract settings, great ingenuity is displayed to get the best of the agents or 'shift-bosses,' any scheme being deemed honest to secure the looked-for ends. As an average 24 shillings per week is earned by a miner, some men making 30 shillings. This is a low pay for skilled miners, but, were more work performed, more remuneration could be offered. In this the 'agents' are probably as much at fault as the men, owing to the tendency to cut the price of a contract should a pair of men do rather better than usual—hence the resort to cunning, and, at times, practical dishonesty.

Probably as 'double-hand' drillers Cornishmen cannot be excelled. At times, in the stopes, one man may turn the drill or 'boyer' to four strikers, whose blows fall in quick succession with the full round swing of the heavy hammers. Air-drills of local manufacture, and built to withstand any ill treatment, are used mostly in development, such as driving ends. Stoping is usually by hand and is let to contractors, either at so much per ton, or so much royalty on the ore raised.

Stoping is conducted both 'under' and 'over-hand.' The 'walls' are usually firm and timber is omitted, especially in the wider stopes, or 'gunnies,' which are so wide that stulls would be impracticable, and square sets are not used in Cornwall. In Dolcoath, about the 400-fathom level, there are some stopes so wide and high that neither wall nor roof is visible. In places the floors of levels have been beaten away, and swinging platforms are constructed, sustained by wire-ropes, or chains, hung from bars driven into the walls. From such platforms, to the light of the candle, nothing is visible but an appalling abyss of darkness. Such places are not altogether safe, as is testified by some extensive 'runs' in the past. To one accustomed to weak walls, the frequently complete absence of either timber or filling seems incredible. Pillars are left, usually in the poorer portions and, of course, the levels are protected by strong stulls, driven firmly into hitches, lagged over and filled.

In the Stope of a Cornish Mine.

Taking Dolcoath as a type of Cornish mines, it is noteworthy that the vein was worked for copper in the upper levels; then came a barren zone, causing despair to the 'adventurers' of those days, and all but the abandonment of the mine, until finally tin was struck, and it has continued to the present day. It is hard to conceive of tin having once been present in the upper portions, or 'gozzan,' of the vein.

Copper compounds are readily soluble in solvents contained in surface waters, as is proved by the leaching of

copper in the zone of oxidation and the precipitation of it below in the zone of secondary enrichment. Tin, occurring practically only as the oxide, is attacked only by a few solvents, and those are not present in any quantity in surface waters. At the 470-fathom level, now being driven and affording practically the lower development on the lode, ore is being raised that carries 1¼ cwt. cassiterite per ton, equivalent to 6.2%. This, of course, is a most excellent grade with tin at over £150 per ton. The increase of heat with depth is not excessive in most mines. In some, thermal springs have been encountered that would render deep sinking impracticable. But, considered all round, provided the ore is payable, no mining or mechanical difficulties will prohibit such mines as Dolcoath being worked to 5,000 ft. vertical. All Cornish mines are burdened with water. In the earlier working of the mines, adits of great length—twelve miles or more—were driven to drain the seepage and to lessen the lift of the pumps. Cornish pumping engines have done good service in the past, but with deeper sinking the Cornish system of raising water is too cumbersome and costly. Today, and in the future, economic requirements call for high-lift electrically driven pumps, either plunger-driven, or the multi-stage centrifugal.

It is instructive to look at practice elsewhere. Take, for example, the Difficultad pump at Pachuca, in Mexico, where the large compound Cornish pump, with a three or four-foot rising main, calculated to raise 5,000,000 gal. daily from a depth of 1,000 ft. below the adit, is displaced by a four-step centrifugal pump, operated by a 750-h.p. asynchronous motor, and with a pump-column of not more than 16 in., still taking care of the water and with a minimum amount of stoppage, which is an important factor in mine pumping. Cheap power will, therefore, be required for deep and comprehensive working in Cornwall; for pumping, winding, stamping, etc., necessitate large supplies of power, and electrical drivage is the best adapted for all purposes underground and at surface.

Looking further into the mining and treatment cost, it is recognized that further economies are possible with modern facilities for the production of 'black tin.' Underground, as far as the actual costs of development and stoping are concerned, expenses are possibly almost as low as the scale of operations will permit. Standing charges, such as pumping and winding, could be lessened with electrical power. Tramming for long distances could be cheapened by the use of electrical locomotives. In new shafts large loading-pockets with self-dumping skips, hauling four to six tons with a winding speed up to 3,000 ft. per min., would lead to further economy. With small crooked shafts—as at many of the mines today—haulage is costly because of the small output and low speed, and in these cases it is unavoidable. Surface traction for ore could be amended by electric traction or belts. Preliminary breaking, sorting, and gradual reduction of ore before passing into the mortars might be amplified, enabling the stamp-capacity to be increased. Adequate slime-saving plant would increase extraction and cut down losses at present passing over the tin-streamers. The attempt to smelt concentrate at the mine and market pig tin in place of black tin would be doubtful, the advantage of the suitable mixing of black tin of different grade and constituents lying with the smelters. The capacity of most mines could be further increased, which, other things being equal, would lessen the cost per ton of ore treated.

Taking Dolcoath as an example, where the tonnage raised and milled is 269 tons daily, or 8,000 tons monthly, producing 145 tons monthly of black tin, or 40 lb. per ton of ore crushed, worth £91 17s. 11d. per ton: For the six months ending December 31, 1905, the receipts per ton were: £1 12s. 10¾d. The charges were: Working cost £1 2s. 6¾d., royalties 1s. 1¼d. Total, £1 3s. 8d., giving a profit of 9s. 2¾d. per ton treated. It is noteworthy that the tonnage treated has been doubled since 1895 and the ore-value lessened by one-half. In 1895 the product per ton was $79.19 per ton of ore crushed, with 4,800 tons milled monthly. The profit for the last half-year was stated at £22,385. No detail of working costs is available and, therefore, it is impossible to more than surmise at economies. A total working cost of about $5.50 compares favorably with gold mines of from two to three times the output. Labor costs are low in Cornwall compared to many camps abroad. Labor is likely to appreciate in value, and so, in order to maintain the same working costs, economies must be effected in one or more of the stages of production or the percentage of extraction must be increased, In order to render payable an ore of similar grade to that at present mined.

Taking all things, therefore, into consideration—realizing the possibility of tin being over £150 per ton for some years—and at the same time not forgetting that this price will stimulate and increase production all over the world, causing £100 per ton to be reckoned as a more conservative standard, the demand for the metal is such that the price cannot well drop before many an old mine is resuscitated in the county of Cornwall. Many mines are indeed already being re-organized, and some are already in actual work, as for instance Wheal Vor in the Breage district, said at one time to have supplied one-third the tin produce of the world, and still not one-half the depth of Dolcoath. It is extremely doubtful, however, if the movement will spread so far as to re-float all the stranded wrecks that lie from Dartmoor to the Western Cape. That a wholesome revival will take place, is assured. It must be borne in mind that most of these mines stopped, not because of any marked falling off of mineral contents, but rather on account of the low price of tin—insufficient to make expenditure and income meet. This is now happily changed, "tin is up," and the event has speedily reacted on Cornish mining. There is no knowing when the movement may stop. Increase of production is possible, and, on the other hand, there is no knowing when a period of financial stress may paralyze trade and, by lessening the consumption of the metal, bring down its price again below the payable limit for the lower grade mines. Increased efficiency and lessened costs will doubtless be attained if capital in sufficient quantity be forthcoming, all of which will enable lower grade ore to be more remuneratively worked than ever before.

Cornwall is awakening, it is attracting the attention of outside capital, the 'cost-book' system is doomed and giving place to 'limited liability' companies. Comprehensive working, modern plants and concentrators, and able administration, will do much to re-establish the industry and give new life to many a barren hillside and lonely moor.

IT is patent that the rock-drill has to fulfil numerous requirements, many of them so conflicting that a compromise is the only possible result. For instance, it must strike a dead, uncushioned blow, and yet work with a variable length of stroke; but to comply with the latter condition the valve must be capable of reversal before a long stroke is completed. It must be strong enough to stand rough usage and yet be light as possible. This means the factor of safety must be cut fine to ensure portability; for it is one thing to carry 200 lb. on a turnpike road, and quite another to drag the same weight up a steep, slippery stope. Compactness is equally essential, as the angle that can be bored in a confined space is chiefly decided by the over-all dimensions of the machine.

Death Valley.

By Robert H. Chapman.

*The area lying to the west and southwest of Salt Lake, as far as the Sierra Nevada, was for a long time known as the Great American desert.

The discovery of gold in California in 1848 was the beginning of the conquest of this thirsty region, the direction of greatest travel being but little south of west from Great Salt Lake to the vicinity of the Donner pass in the Sierra Nevada, since used by the Central Pacific railroad in crossing the range. In seeking for better routes to the new El Dorado, parties journeyed southward across the wastes of sand and rock searching for lower passes that would be perennially available. In this direction the number of mountain ranges to be crossed is largely increased, but by going well southward the great wall of the Sierra Nevada is escaped, though the desert journey is lengthened and the hardships encountered by many parties were most appalling.

Death Valley.
From the Summit of Grapevine Range.

The desert took frequent toll in the lives of man and beast, and indeed does sometimes today, though the dangers are now comparatively insignificant.

With the discovery of the Comstock mines there came a period of tremendous activity in the search for the precious metals, more particularly for silver, and much of the desert region was traversed by the hardy prospector and his burro. In this way the long distances between watering places were divided by the discovery of springs and 'tanks' (natural reservoirs), and gradually this part of the desert diminished in area and lost some of its fearfulness.

In the '60s and in 1871–72, government expeditions under Lieut. George M. Wheeler traversed several routes across the desert, making topographic sketches and notes of interest, but few complete maps were printed. In 1865, and several times since then, the boundary line between Nevada and California was run, which cut through much of the most difficult country. The reports of members of these expeditions did not tend to populate the region with great rapidity.

In many instances prospectors were successful, and the camps of Silver Peak, Lida, Reveille, and others sprang up, and had their periods of prosperity and decline, becoming completely uninhabited.

During the period of activity many travelers became permanent residents, took to wife dusky maidens from the Indian tribes, and started ranches at various springs and streams, oases in the expanse of waste, where small herds of cattle or horses were maintained.

On the east the Mormons pushed gradually away from the streams of southern Utah and established farms and ranches at such places as furnished water, but there is a belt of country one hundred miles or more in width between these points and the water-fed valleys at the foot of the Sierra Nevada, which is almost wholly barren and very dry.

In Death Valley.
Sand Dunes and Mesquite Roots.

During the last few years, beginning with the discovery of valuable ore at Tonopah (in May, 1900), the attack

*Abstracted from the *The National Geographic Magazine*. Mr. Chapman was in charge of surveys for maps of this region prepared by the U. S. Geological Survey.

upon this desert has been renewed with great vigor and earnestness, and the efforts of the seeker of fortune met with so much success and at such widely separated points that it was decided by the officers of the Geological Survey to put parties in the field to make a reconnaissance of some of the unmapped desert area.

The idea of the average man is that the desert is a great plain, sand-covered or rock-littered, with nothing to relieve the monotony of the horizon. As a matter of fact, these great areas include mountain ranges, high plateaus, mesas, and buttes, extensive valleys, that in the clear air seem but a short distance across. Many of these valleys are 'closed'—have no outlet—and the lowest pass from one to another is often many hundred feet above the valley floor. The flowing streams are very few, the springs far between, and water a commodity for which men search, often with life at stake.

Twelve miles southwest of Bullfrog, camp is made at the Daylight spring, on the crest of the divide between the Amargosa desert and Death Valley. We journey to one of the high peaks of the Grapevine and look into the "Valley of the Shadow of Death," as desolate a view as may be found.

In the distance the Telescope range rises to an elevation of nearly 11,000 ft., while at our feet the salt-white plain is more than 6,000 ft. below us and well below sea-level. The flat is 25 miles away, and on its borders not a vestige of vegetation appears. The valley was named Death Valley from the loss of members of parties of emigrants who attempted to pass through it in 1849, and since then a number of persons have been lost, keeping up the sinister record as a graveyard, but the appalling stories of the number of persons perishing there each year are exaggerated. It is not safe to go into Death Valley for active work during July, August, and September, though there are persons who remain there all summer; but in October we journey from Daylight Spring down hill, mile upon mile. A sign painted upon a box lid stuck into a pile of stones gives us the cheerful assurance that we may be well provided for if we are found; it reads: "Rhyolite Undertaking Company, funeral directors and embalmers."

The cañon walls rise above us, not high, but sharp and steep, and it is only by turning and looking backward that we appreciate the greatness of the range we have crossed. The grade is easy, the road wide, sandy, and gravelly, our horses grow weary and move with deliberation; all are oppressed with the feeling of weariness and lassitude.

We ride from the cañon mouth to the edge of a sandy plain, and here, 115 ft. below sea-level, find a couple of holes, five feet in diameter and about as deep, with two feet of water in them. This is the Stovepipe spring, so named from the fact that it was long marked by a section or two of that useful flue, placed upright, to inform the wayfarer where to dig when the holes had been filled by drifting sands hurled forward by the furious gales, burying deeper and deeper all vestiges of the water so necessary to life itself. We are indeed in *the* Valley; around us the sand drifts in little sheets; here and there a surface of broken and ragged saline material, hard and as rough as though made of giant saws set with teeth edge up.

We turn to the eastward; in the foreground the gritty beds of conglomerate and hard clays show as low hills backed by the ragged cliffs of the Grapevine, banded, rugged, and grim. To the northward the cliffs and peaks guard this valley of desolation, the long delta fans of drift material spreading like great hands from the mouth of each cañon, burying from sight all vestige of the underlying rock, each a silent witness of the cloudbursts, which sometimes come roaring down the rock-bound clefts, to spread and evaporate like magic in the fierce rays of the sun. The farthest fan marks the mouth of Titus cañon, named for the young Coloradan who left Bullfrog about the time we reached Goldfield, and perished in its lower reaches seeking water, as attested by the message penciled upon a sliver of stick broken from a provision box and left sticking in the sand for the guidance of his companions: "Have gone down cañon looking for the spring; have been waiting for you — TITUS." His remains were found; those of the friend are still resting undiscovered.

Across the flat we journey, our light vehicle loaded to its limit with food, forage, and water, the mules weary before starting. Dunes surrounded us, 20 to 30 ft. high, representing the struggle of plant life to keep its branches above the accumulating drift and its root near enough water. The victory is eventually with the sand, into which wheels and hoofs sink nearly a foot, or when a harder surface is found it breaks like crusted snow, letting the beasts into a soft substance which they dislike exceedingly. Through such ground we can move but a few yards without stopping. In places great boulders obstruct the trail, among them the wagon must twist and turn through the fickle and shifting sands which often hide all signs of previous travel.

About 25 miles southward from the Stovepipe spring, Furnace creek flows from the lower part of a large wash which heads in the Grapevine range. Here is one of the properties of the Pacific Coast Borax Co., which years ago constructed small irrigating ditches, sowed hay and planted trees, built houses, and established a plant for the treatment of the salts in the flat near by.

At 225 ft. below sea-level are about 100 acres of emerald-like fields, long rows of fig trees, and abundant running water, while behind the frowning cliffs and sharp peaks of the Funeral range guard the valley from the advance of the treasure-hunter from the East.

The borax plant is now idle, though the valuable beds are still owned by the company, which maintains a resident superintendent or foreman. The white flat which we saw from the mountain is composed largely of salt, borax, and gypsum. The surface is as rough as can be imagined; it consists of ridges, blocks, and plates on edge, inclined, and flat, with shallow drains full of dreadfully salt water. From these drains the mixture of salt and other material is taken, molded into forms, and set up at various places to mark the corners of the mineral claims. This material dries out, and, when the molds are removed, stands like solid marble blocks, which remind one of the fate of Lot's wife. Here we are informed that during the summer the temperature reaches more than 130° in the shade, and that the nights are too hot for sleeping, but during our visit in November the weather was beautiful except during the fierce sandstorms.

Much of the real development in Death Valley has been done by the parties interested in borax, which is found here and in many parts of the desert region. The 'cotton-ball' (borate of soda) is found in the flats, but colemanite (borate of lime) is found in the hills and mountains, high above the flats of the valley bottom. At one time it was attempted to refine borax at Furnace creek, but no work of gathering or treating is now done there. The freight teams of the company bring provisions every few months. From here the now famous 20-mule team hauled to Mojave; such teams are often seen along the lines of communication in the desert, but few have so many animals or such heavy wagons.

There is one way to become famous in Death Valley — that is, to die near to a trail so that one's remains may be found. For instance, meeting a man one day, I inquired about the route, water, etc. He said: "The

road is plain for ten miles, when you'll find a well about 100 yards to the right; the water is salty, but your mules will drink it. Six miles farther you'll come to 'Tim Ryan, Aug. 9th, '05,' and two and one-half miles southeast of him you'll find plenty of good water."

From the valley where, even now in November, the temperature is between 80 and 90° during the day, we cross to the Panamint range. At the mouth of Cotton-

Reveille Range.

wood cañon we halt for lunch, having covered eight miles during the morning, and find numerous hieroglyphics on the walls. These illustrate Indians fighting over water, and depict a running stream, the bighorn sheep, and various animals and birds.

Twelve miles up this 'wash' we find cottonwood trees,

Kawitch and Quartzite Mtn.

some grass, a running stream, and quantities of watercress, which the mules attack with evident relish. Here we find numerous prospectors, learn of an abandoned camp to the north, and water and trails everywhere.

In the Grapevine and Panamint ranges there are still a few mountain sheep. Tracks near water-holes and a few old skulls are the nearest we come to a view of these shy animals.

To the northward we follow along the range, often in sight of our valley camp miles away, and 48 hours after leaving the summit of the valley we are camping 9,000 ft. above it, wading in snow varying from ankle to waist deep, with shoes and stockings frozen hard.

In the Panamint range, both sedimentary and volcanic rocks appear, and near one of the contacts of these we travel up a wonderful cañon. The walls are so near to one another that on horseback one may touch both at once. The material is limestone that has been baked into marble of alternate beds of black and white, about a foot in thickness. This trail is one of the old Indian routes to the Valley from Keeler and the Sierra Nevada.

From the summits of the Panamint range we look into the Panamint valley. Similar to Death Valley in form, but a little higher in elevation, the floor is 6,000 ft. below the mountain tops and about 1,000 ft. above the sea.

Death Valley is by no means the driest of the regions traversed, but the heat and heretofore the inaccessibility have made it difficult. In the mountains flanking it are

Marble Canyon.

numerous springs and frequent water-holes which, though dry in summer through excessive evaporation, are available during the fall and winter. There are many springs that are credited as poison water; one of these we sampled, but unfortunately the bottles were broken before analysis could be made. In my opinion, there are springs in which arsenic is present, but most cases of sickness or death are probably due to drinking excessive quantities at one time, followed by physical exertion in the heat. Such springs as the Indians will not use are better left alone or used in extreme moderation, by no means an easy thing for one throat-parched and speechless for need of water. Each spring is a source of supply for birds, many of which are very tame.

Great mountains are a joy to the lover of nature; they are an inspiration to the artist, and express grandeur and nobility. The desert has no such spirit, but has a wonderful fascination, born of the impressiveness of magnificent distance, limitless sky, and the infinite patience of an unbreakable calm.

Prospecting for Rare Minerals and Earths.

Written for the MINING AND SCIENTIFIC PRESS
By GEORGE E. WALSH.

The remarkable strides made in the electrical industry have stimulated a demand for many minerals and earths that were formerly of little commercial value. In the laboratory many of these had their uses, but they were not considered of sufficient importance to attract attention to the mining of them. The electro-chemist has secured results that now give value to deposits containing tungsten, vanadium, uranium, and molybdenum. In searching for some metal that would give better incandescent results than carbon filaments, the electro-chemist has developed a series of rare earths. A good many of these were formerly imported, but today new deposits of them have been discovered, and in some instances the domestic products are superior to those brought from Europe.

The oxides of several rare metals are very refractory, and their use in making glower mantles and incandescent-lamp filaments has created such a demand that it is profitable to prospect for them. Most of the new filaments for incandescent lamps are manufactured from several of the rare earths in such proportions that highly desirable results are obtained. The Nernst lamp, for instance, is composed of 85% zirconium oxide and 15% yttria earths. The latter include a mixture of several oxides that occur together in certain minerals, most of which have a high refractory power.

Until within a few years the yttria earths were obtained almost entirely from the minerals gadolinite and yttrialite in Norway and Sweden. Today, however, the best deposits are found in Llano county, Texas. The deposits found in Texas are in a small district, and are probably the results of volcanic eruption. They are radioactive, and are found in pockets in the quartz. The presence of the earths is indicated by a bluish discoloration from the quartz. It is a simple matter to recover the yttria earths from these deposits of gadolinite and yttrialite, and they make the best lamp glowers used in the trade.

The superiority of the Texas deposit to that obtained from Scandinavia may be indicated in the relative atomic weights. Yttria earths of the greatest atomic weights give the most satisfactory results in glowers. The atomic weights of the Texas ores range from 100 to 115, while the imported ores are as low as 90 to 92. The discovery of other deposits of yttria earths in different parts of the country indicates the possibility that the use of them may modify the development of new lighting systems.

Zirconia has always been used to some extent with gas lamps and mantles, but in the early development of this industry the glowers were made chiefly with stuff that was obtained from chemical supply houses. Uniform results could not be obtained from such material. But now good zircon ore, a zirconium silicate, is found in abundance in Henderson county, North Carolina. This ore contains 67% zirconium as oxide. The ore is mined in considerable quantity and ground fine in a ball-mill with twice its weight of crude acid potassium fluoride. In this condition it is then thoroughly fused in a graphite crucible until the ore is completely dissolved. Reasonably pure zirconium is obtained. Absolutely pure zirconia is not necessary for the electrical industries, but anything more than a few traces of silica would cause a rapid change in the potential difference at the glower terminals and thus diminish the power of the light and shorten the life of the glower.

The development of the tantalum lamp has been due chiefly to the work of securing a material that has a greater luminous efficiency than the carbon filament. Carbon filaments cannot stand the high temperatures required for the best lamps, and the search for a proper substitute has resulted in experimental tests with a great number of rare metals and earths. The experiments with the osmium lamp increased the demand for this metal, but this is quite rare and the price has been greatly against it. The resistance of osmium is comparatively low, and it becomes soft at high temperatures. Tantalum, however, is a metal that has a higher fusing point than platinum, and it can be maintained at a high temperature for a long period. For a lamp for 110 volts about two feet of tantalum wire is used, but the wire is exceedingly thin, and about 45,000 filaments can be made from one kilogram of the metal. At present the cost of obtaining the metal from its ores and drawing it into thin wires determines the price of the filaments in the market. Tantalum is not a rare metal, and it is found in considerable quantities in different parts of the country. But there is a great difference in the purity of the ores. Given the pure metal there is not much difficulty in drawing the wires. It is not easy to extract the metal from its ore. At present the method of treatment is to prepare a mixture of tantalum fluoride and potassium fluoride, which is reduced by potassium, and the product is subjected to fractional distillation. The mass of tantalum thus obtained can then be treated as any ordinary metal and drawn suitable for the trade. The crude material is cheap, but the refined metal is expensive, owing to the cost of recovering it.

The best tantalum-bearing minerals are found in the Black Hills, South Dakota. The deposits there are rich, and while ordinary tantalum-bearing minerals are quoted at $7 to $10 per unit, according to the percentage of tantalic acid contained in them, the best ore from the Black Hills commands $20 per unit; in other words, the ore ranges from $250 to $500 per long ton, showing that the quality of the deposit has an important bearing upon the pure metal in spite of the difficulties of refining. The amount of tantalum used today is comparatively unimportant, but its steady improvement in incandescent lighting promises to effect a great change in this respect.

The other important field in which rare metals are receiving attention is in the iron and steel industries. This is not so distinct from the electrical field as may appear at first sight, for the manufacture or recovery of many of these metals is due to electrical processes. The electro-chemist was the first to discover the peculiarly valuable properties of the ferro-alloys in hardening steel, and the electric furnace has proved an important factor in giving a new value to tungsten, molybdenum, vanadium and uranium. The mixture of these with steel, to toughen and harden it, has become the accepted practice of all mills where special grades of hard steel are made. As a result the demand for these ores has increased rapidly.

Until a few years ago most of the tungsten ores were obtained from mines in Australasia and Europe, and an industry was built up in Germany, France, and England in manufacturing the refined metal. The tungsten ore as mined was seldom used by these European concerns, most of them using a concentrate containing upward of 60% tungstic acid. But the discovery of good tungsten deposits in this country has stimulated manufacturers and miners to renewed interest in the raw product. The largest producing area is in Boulder county, Colorado, but more recent discoveries have been made in Arizona, Idaho, Wyoming, Washington, and California. These deposits show wide variations in quantity and quality, but the richest prove exceedingly profitable. Some of the tungsten metal obtained from these mines analyzes as high as 99%, and when it contains very little carbon it

sells from 75c. to $1.25 per pound. No chemical compounds can equal this for steel-making, and English and German steel makers have begun to consider the wisdom of importing the American metal for their work. It is therefore more than likely that within a few years we may be an exporter of high-grade tungsten instead of an importer.

Prospecting for tungsten is not a bad business. Last year a small prospector stumbled upon deposits of tungsten ore in Wyoming that had been considered of no commercial value by scores of miners in the past; a company was organized, and today it has an efficient little plant, paying far better dividends than many of the mines of more precious metals within a radius of 500 miles. In this case the concentrate obtained proved remarkably free from phosphorus and sulphur, two of the most objectionable impurities, and hence the profits on the investment.

The manufacture of molybdenum has also increased rapidly with the greater use of this metal in steel-making. The molybdenum adds greatly to the malleability of steel. Along with tungsten this metal is becoming an important factor in manufacturing, especially for the best tool and armor steel. The molybdenum is obtained from molybdenite, a bluish-gray mineral, which greatly resembles graphite in appearance. The value of the ore depends upon the amount of molybdic acid it contains; this varies from 90 to 98%. When containing the high percentage the ore may bring $400 per long ton.

In this country the best deposits of molybdenite are found in Maine and Washington. Canada produces a fair amount, and deposits have been found in British Columbia. Small deposits are also reported in Arizona and New Mexico. So far the supply has not been excessive and all that has been mined has been consumed in our domestic steel-making. In addition to this, we are steady importers of the metal from Canada and Norway, paying 20% duty on it. The more recent use of molybdic acid in the manufacture of high-grade smokeless powder has increased the demand.

The employment of vanadium to increase the tensile strength of steel and its elastic limit has greatly increased the demand for vanadinite ore, from which vanadium comes. Vanadium, like uranium, was not supposed to be obtained in paying quantities in this country until lately. Deposits of the ore were found in South America and other parts of the world, but little systematic search was made in the United States. But today the vanadium obtained from the carnotite ore mined in Colorado has proved so satisfactory that much of it is exported to France for steel-manufacturing. The French have been the most progressive in utilizing the ferro-alloys for hardening, toughening, and otherwise improving their steel, and the fact that the American vanadium is considered best by them is good evidence of the value of the deposits in the West. Vanadium-bearing mineral deposits are also found in Arizona and Utah. Some of the ores contain only 10% vanadic acid, and are worth only 40c. per lb., but others having from 25% upward sell as high as $2.75 per pound. The recovery of vanadium from the carnotite is not a costly process, and improvements on the method are simplifying and lessening the cost each year.

Uranium was once considered a show metal, or one to be used for laboratory practice, but now that the industry of developing the ferro-alloys for commercial purposes has reached a high stage, this metal also is increasing in value. It is employed in the preparation of black pigments and for imparting certain desirable qualities to steel. In the steel industry uranium is used chiefly in combination with other ferro-alloys, and the demand for it is steadily increasing. Uranium ore is found in Colorado, Utah, and California, but in comparatively small quantities. If the present demand for it continues, prospecting for it will become necessary or the supply will have to be imported. Ore containing 10% uranium oxide is considered of commercial value, and any showing a higher percentage commands much larger prices. Samples showing as high as 20% oxide have been obtained from Colorado. It is believed by the best mineralogists that there are rich deposits of uranium in the Rocky Mountain region and that they will be discovered within a few years. The lucky prospector may find by that time that such a mine is of more value to him than one of gold or silver. The metal is sufficiently rare in all parts of the world to make prospecting for it worth while.

Radium.

The discovery of the property of matter known as radio-activity is probably the most important achievement of physical science since Newton taught us to understand gravitation. It has advanced our knowledge of the physical constitution of the universe nearly as much as the work of Darwin advanced biological theories as to the origin of life. The twentieth century, indeed, promises to carry the story of evolution one stage farther back than did the nineteenth. Darwin has enabled us to see how the process of evolution, dimly guessed at by philosophers and poets for twenty centuries, may actually take place in that still mysterious entity which we call living matter; how the structureless cells of protoplasm, which were almost certainly the first representatives of life on the earth, have, through the lapse of uncounted and immemorial ages, given birth to man himself and all his high hopes and wonderful works. The chemists and physicists who have been working at radio-activity for the last twenty years have carried the process of evolution farther back, and applied it to inanimate matter. Till within the last generation the atom as defined by Dalton was the ultimate concept of the student of Nature. Every material substance was found to be composed of the so-called atoms of some sixty or seventy elementary bodies, which no method known in our laboratories or discovered in Nature could split up into simpler forms. These atoms were thought to be indivisible, permanent, with no visible beginning and no apparent end. But we are now in the full glamor of the discovery that these atoms themselves are but highly complicated arrangements of still smaller entities, the 'corpuscles' which Professor J. J. Thomson predicted many years ago from mathematical considerations, and which the recent researches into radio-activity have definitely established as existing uner the name of electrons. It is now believed that every atom is a system of these tiny electrons, which are in constant motion like that of the planets in our solar system, and owe their remarkable stability to that very motion. Some atoms, like that of hydrogen, consist only of a few hundreds of these electrons, while others, like that of radium itself, probably contain hundreds of thousands of them. These electrons are thought to be all precisely similar, and it is probable that they constitute that primitive *ur-stoff*, or primordial matter, which many speculators have held to be the foundation of the material universe. Further, it is practically certain that they are closely related to electricity, consisting either of particles of this primitive matter, each of which bears a unit charge of electricity, or perhaps solely of such electrical charges, without any material basis at all in the usual sense of the word. This far-reaching hypothesis promises to revolutionize our views of the ultimate constitution of the universe, and forms the most fascinating addition to physical or chemical theories which has been put forward within living memory.—*The Spectator.*

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

In an action of trespass for taking ore from the claim or vein of another it makes a difference whether the person taking such ore was an innocent or a willful trespasser. An innocent trespasser is liable under the law for the actual value of the ore taken, less the reasonable cost of extracting the ore, raising it to the surface, transporting it to the mill, and reducing or milling it. But he is not entitled to claim any mitigation of damages for money expended in the running of levels, sinking of shafts, or development work, except to the extent actually necessary to the extraction of the ore in controversy. Neither can an innocent trespasser charge for any extraordinary expenses to his plant, or any wages to any persons except those actually employed and engaged in extracting, transporting, and milling of the ore in question.

Montana Mining Co. *v.* St. Louis Mining, etc., Co., 147 Fed. 897.

In an action for trespass for taking ore out of a claim and vein of another where extra-lateral rights were involved the trial Court stated the rule in its instructions to the jury thus: "Where one has the apex of a vein within the surface boundaries of his mining claim, and is entitled to extra-lateral rights thereon, such vein belongs to such person, and the possession of such mining claim is possession of such vein in its downward course to its uttermost depths, and the entire vein is treated and considered under the law the same as though it, in its entirety, was wholly within the surface boundaries of said mining claim, and a trespass thereon by third person is treated and considered the same as though it was a trespass upon said claim within its surface boundaries."

Montana Mining Co. *v.* St. Louis Mining, etc., Co., 147 Fed. 897.

Whether the question was as to whether or not a trespass was innocent or willful, as controlling the amount of damages, a trial court gave the jury this rule: "In determining the question of good faith of defendant in extracting and removing the ore in question, you are entitled to consider all the facts and circumstances shown by the evidence. If you find that the defendant acted under an honest belief that it was the owner of the ore in the disputed ground, and had good, right and lawful authority to extract the same and that such belief was based upon such facts and circumstances as that you believe that an ordinary man, acting as you find the defendant acted, would have had the honest belief that he owned such ore and had a right to remove it, then the trespass was not willful."

Montana Mining Co. *v.* St. Louis Mining, etc., Co., 147 Fed. 897.

Where a statute required that the upper and lower landings at the top of a mining shaft should be so securely fenced as to prevent either man or materials from falling into the shaft; the statute also gave a right of action for any injury occasioned by willful failure to comply with such provision, and provided that the defense of contributory negligence or assumption of risk could not be pleaded. It was decided by the Court that the purpose of this statute was to guard against the accidental falling of man or materials into a mining shaft, and that it had no application to the case where a miner voluntarily put his head through a fence into a shaft and was struck and killed by a passing cage.

Springfield, etc., Mining Co. *v.* Gordon, 147 Fed. 690.

An action to recover a per cent of the proceeds of gold according to the terms of a lease, to obtain an injunction against the lessee, preventing him from removing any more gold from the mine, to obtain an accounting of the gold taken under the lease, and the appointment of a receiver to hold the property pending litigation, was held to be essentially an action in equity, and that an equitable defense could be pleaded.

Kuzek *v.* Magaha, 148 Fed. 618.

The Tempering of Drill-Bits.

*Even a well-formed bit will be unsatisfactory if badly tempered; there are several methods of hardening, the degree of hardness imparted to the cutting edge depending principally on the temperature of the steel at the moment it is quenched. There are several good reasons for hardening directly sharpening is finished, known as 'plunging off the anvil,' but the great objection to the plan is that no particular temperature can be assured at that moment. To secure uniformity, therefore, it is best to reheat the steel, but the heat should be short, the object being to provide a hard cutting edge with a tough backing. Even when care is taken, the length heated is generally in excess of that to be hardened, and if the bit is cooled, the last 1½ in. at least at the end will be found hard, and more or less brittle. This may, in a measure, be rectified by decreasing the degree of hardness, a process known as tempering. When the hardened bit is again heated, the hardness passes off, not all at once, but gradually, each successive stage of decreasing hardness being recognizable by the color on the surface of the steel. These colors show up vividly on high-grade steels, and faintly on poor qualities; in each case they are easier to discern if the surface of the metal is brightened. On being heated to 440° F. the bit, which was when dead hard of a grayish white color, begins to tinge with yellow, and the softening process should be stopped by quenching in cold water; the same color serves also for hammer heads. If the heating is continued to 470° F., the color will be full yellow, or straw color; at 490° F. an autumnal shade of yellow brown is seen; both these colors are suitable for metal turning tools. The full brown, or copper color, at 510 to 530° F., is used to taps, dies, and axes; the purple blue at 540° F. for chisels, cutlasses, and knives; at 600° F. is the full blue spring temperature for saws, and if heated beyond this point the effect of the original hardening is lost.

The temperature to which drill-bits should be let down is therefore 440° F.; a degree of heat which can be secured by placing the hardened bits in a molten mixture of one and three-quarter parts lead and one part tin. There is not the slightest doubt that an excellently hardened drill results from this system of tempering, but unless the above hardening bath is used, the time occupied is an objection. The smith has to watch the slowly heating bit for the required shade of color, and be ready to cool it when that shade is reached. To meet this objection, the following alternative plan is offered, the product is equally uniform, and the author has employed it with great success, having first noticed the idea in Colorado.

The hardening tank is provided with a diaphragm of coarse wire gauze, placed horizontally and supported at frequent intervals to keep it quite level; the cooling water enters near the bottom of the tank, and the overflow is fixed so that the water shall cover the screen to a depth of half an inch. Racks are placed above the tank to hold the drill shanks in a vertical position. The heated bit is simply placed in the tank where it rests on the wire gauze, only the last half inch of cutting face being below the water, and is maintained in an upright position by the rack. If a bar of steel one inch in diameter were treated in this manner, it would stand a chance of being ringed at the water-level; but owing to the thinness of the ribs this will not occur to the bit, provided it is not overheated. The thin tumbler stands boiling water, while the thick one cracks; the heated end of the bit is in contact with a comparatively small body of water, and the thin ribs conduct the heat and prevent any sudden contraction or 'ringing.'

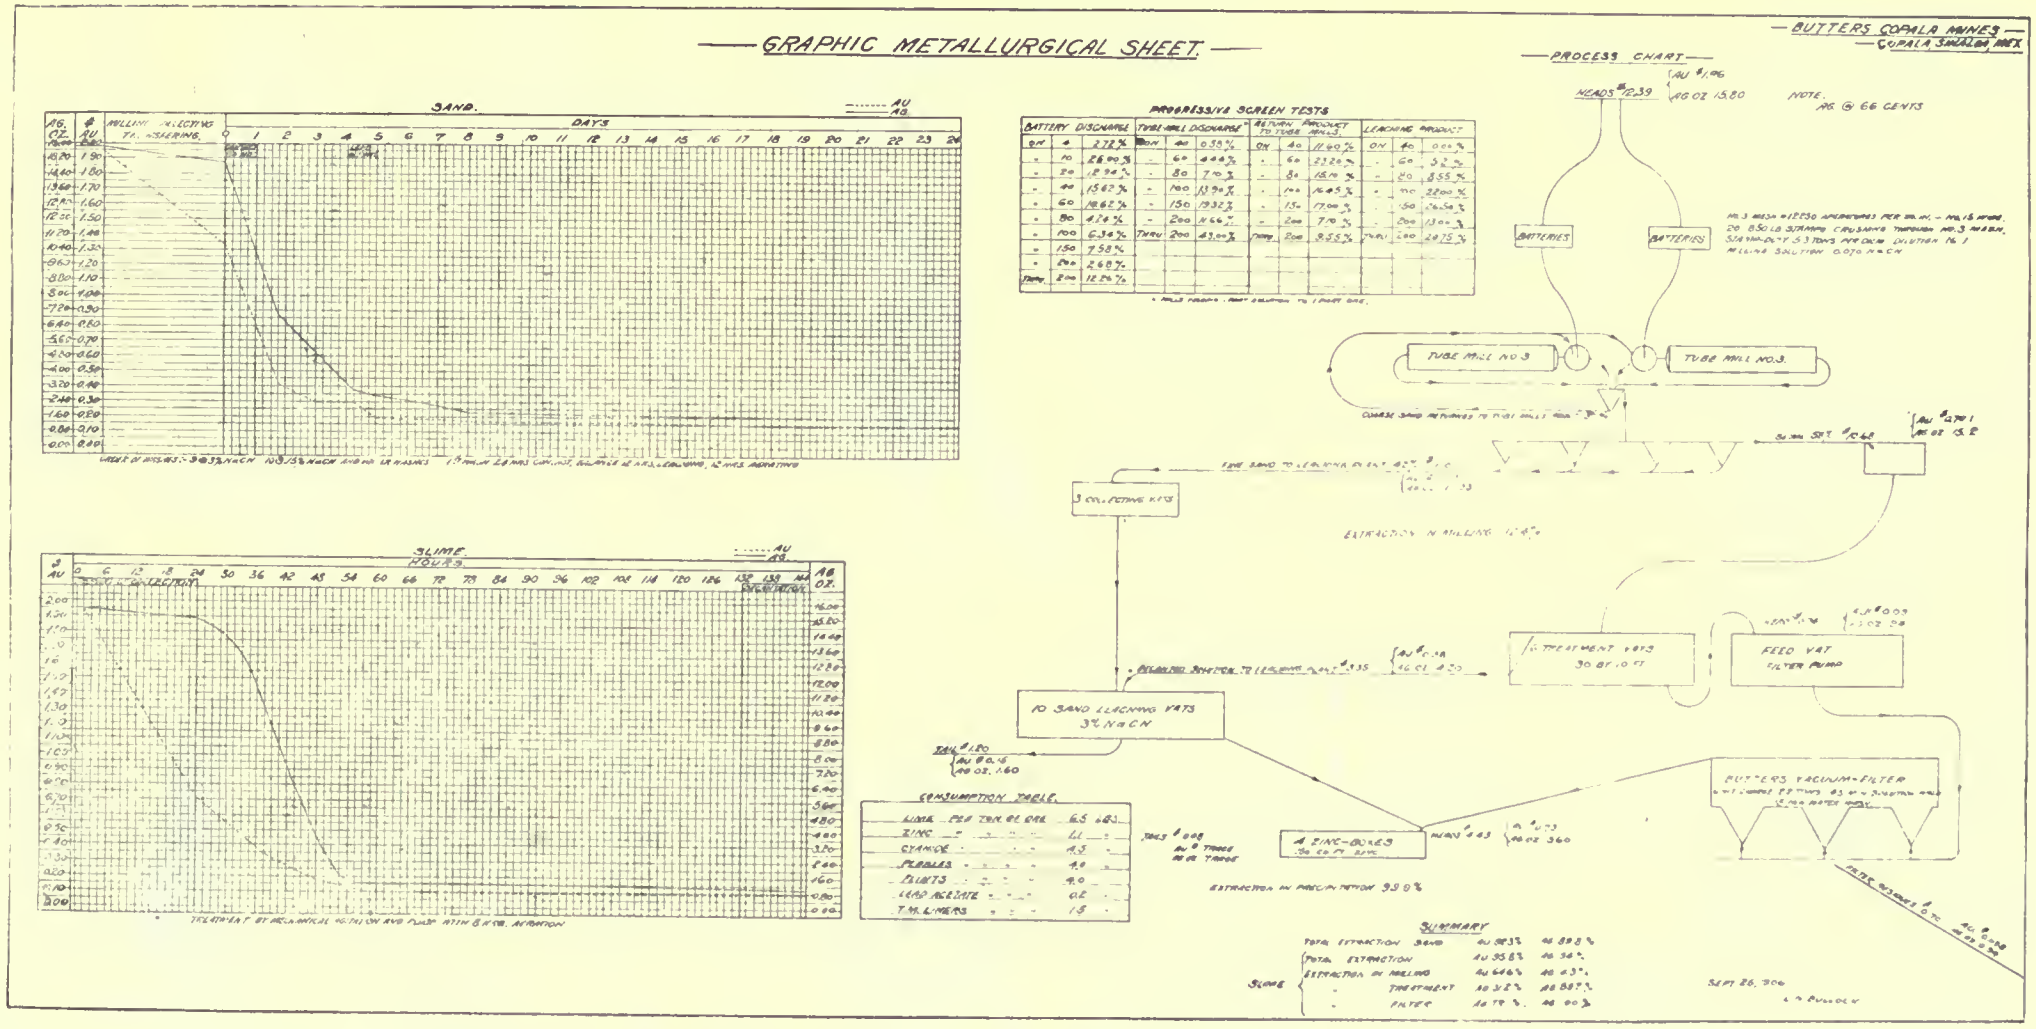
MINING AND SCIENTIFIC PRESS.

February 16, 1907.



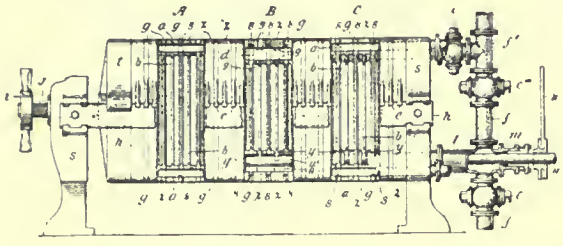
Metallurgical Chart of Operations in the Mill of the Butters Copala Mines in Sinaloa, Mexico.

This graphic presentation of the work done in a cyanide mill needs no explanation, at least, to those who are interested in the subject. The Butters filter is the main feature in the practice illustrated by this chart. By the use of it the same work is accomplished in five days as would be done by the decantation and wash system in two weeks. The ore is valuable for its silver, which occurs as a sulphide. We are informed by Mr. L. N. Bullock, who made the chart, that the use of lead acetate in the treatment of sand has proved efficacious; the tube-mill also has been most satisfactory for re-grinding, especially as the ore is unusually hard.

MINING AND METALLURGICAL PATENTS.

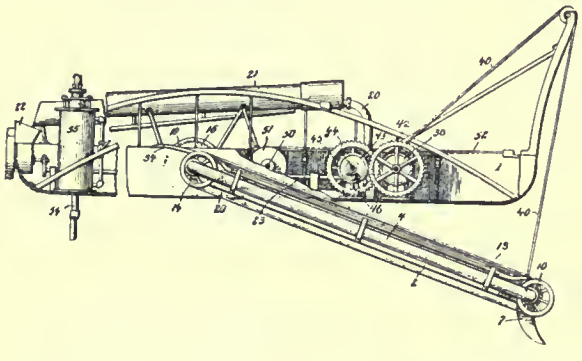
Specially Reported for the MINING AND SCIENTIFIC PRESS.

PRESSURE-FILTER.—No. 842,484; Charles W. Merrill, Lead, South Dakota.



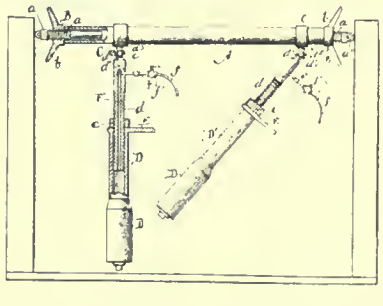
In a pressure-filter the combination with suitable filter-plates, of a container provided with a direct opening through which a cleansing medium may be introduced in any desired direction into the space within the container, and with a direct outlet through which the mixture of cleansing medium and unfilterable component is discharged.

GOLD-DREDGE.—No. 842,383; Horace J. Clark, Boise, Idaho, assignor to The Clark Dredging Company, Chicago, Ill., a Corporation of Nevada.



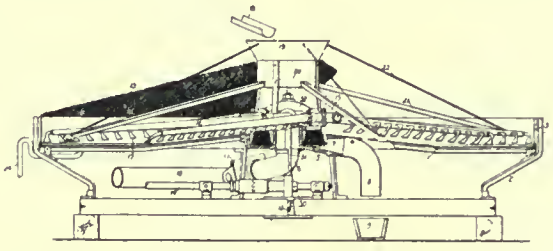
In a dredge, a suction-pipe formed in a plurality of sections, means for independently operating said sections, and scoops carried by said sections and provided with an inlet-opening for material thereto, and a priming-chamber disposed intermediate of said sections and connected with a source of supply.

MOUNTING FOR ROCK-DRILLS.—No. 842,654; Martin Hardsocg, Ottumwa, Iowa.



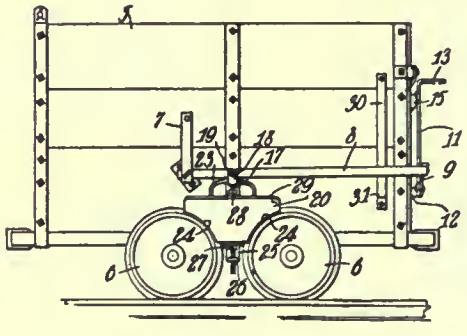
A mounting for rock-drills, consisting of a support adapted to be maintained in a suitable position with respect to a fixed abutment, a screw between the support and the abutment, a nut for regulating the pressure exerted by the screw against the support, in combination with a rock-drill having an extension or barrel rigidly secured thereto, a tubular screw-threaded shank adjustably secured to the support and entered into the extension or barrel and provided with a pressure-supply passage leading to its interior, a handle for forwardly projecting the barrel during the drilling operation, and a follower-nut on a screw-threaded shank for locking the barrel and drill in projected position, substantially as described.

AMALGAMATOR.—No. 841,990; Henry L. Lightner, San Francisco, Cal., assignor of one-third to William Priest and one-third to Henry Feige, San Francisco, California.



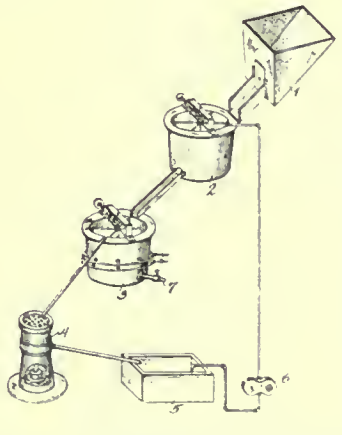
In an apparatus of the character described, the combination of an amalgamating-table having in the middle portion thereof a channel, and a chute leading therefrom, an air-chamber, hollow-arms extending from said air-chamber, nozzles connected with said arms and discharging downward and inward on said table, and means for feeding material to the periphery of the table, substantially as described.

MINE-CAR BRAKE-SHOE.—No. 841,264; Daniel S. Miller and John M. Landfair, Black Lick Station, Pennsylvania.



The combination with a vehicle, of a yoke pivotally mounted on the vehicle, a rod depending from the yoke, a brake-shoe adjustable vertically of the rod, a guide member passing through the rod and loosely mounted in the brake-shoe, and means for locking the brake-shoe in adjusted position. A vertically-adjustable brake-shoe pivotally mounted on the yoke and adapted to bear against the vehicle-wheels, a guiding member carried by the yoke and loosely mounted in the brake-shoe, and means for locking the brake-shoe in adjusted position.

PROCESS OF CONCENTRATING ORES.—No. 842,255; Alfred Schwartz, New York, N. Y., assignor to Schwartz Ore Treating Company, Phœnix, Ariz., a Corporation of Arizona.



The method of concentrating ores consisting in mixing with the pulverized ore rosin-oil, then separating said agent with its entrapped values from the tailings, and finally recovering the values from said agent.

A Platinum Coinage.

*The Russian Urals supply 95% of the world's platinum, and its production is in the hands of half a dozen concerns. It has been so for nearly a century. Without knowing even the meaning of the word 'trust,' these parties, by their very fewness, can always easily reach an 'understanding.' The Russian Government watches very closely the production of platinum—knows to a shave the annual production, and how the world is dependent on the Urals for its main supply—and is not slow to take advantage of this fact, and in turn have an 'understanding' with the few mine-owners. The increase in price in platinum is one of Russia's little helps to 'recuperate' after the late disastrous war. Japan did exactly the same thing with camphor. Knowing the world must have the Formosa article, the price has more than trebled during the past decade.

At one time, Russia had on hand such a stock of platinum that the question was what to do with it. It was a veritable 'drug on the market.' Finally, after years of 'chewing the cud' over the platinum glut, the Government hit upon the idea of using it as money. For seventeen years—from 1828 to 1845—the Petersburg national mint issued millions of francs' worth of money of fine platinum. The pieces were of three, six, and twelve roubles. Altogether the equivalent of a couple of million dollars' worth of platinum money was issued. Many specimens of these are still to be seen in collections at Petersburg.

Then the end came to platinum as a money-metal. To translate textually from a Russian source the motive for its discontinuance: "The essential quality of a monetary metal is its power to pass almost without expense from the form of the ingot to that of money, and *vice versa*. An ingot of gold duly refined can be moneyed, and the money thus obtained be re-cast in ingot, without the total expense of this double operation (coining and re-melting) exceeding one-half per cent of the value of the fine metal. For platinum—very difficult to work—the expense of the double operation would be relatively enormous."

What became of the platinum-money millions? Although officially withdrawn from circulation over half a century ago, it is estimated that less than a million dollars' worth has been received back into the national treasury, or otherwise heard of, during all the period elapsed. The other million or more is slummed away here and there among the stocking-hoardings of the Russian *mujiks*, in remote villages where little is heard of the outside world. These hoardings will go from father to son. If they find they cannot pass them at the nearest market towns, they simply take them back home, and throw them into the savings-pot or stocking. The average Russian peasant is so dense and so removed from any sources of information, that he will hoard paper roubles for years after they have been officially called in, and after notices thereof have been published in the official gazettes throughout the land. Of course he cannot read, and probably knows nobody who does, so he one day learns (years after the currency is obsolete) at the distant bazaar that his hoarding is valueless as Jeff Davis's scrip. Naturally discontent ensues, and the result is often one of those minor peasant insurrections incomprehensible to foreign nations.

However, in that hoarded platinum-money there is a million dollars' worth of platinum-fine assured 'in sight' to those who care to hunt for it. The question is how to find it. It would mean a journey of a couple of years from village to village—a knowledge of tact, and of the Russian language, so eminently requisite when inquiring into such a sensitive subject as a *mujik's* hoardings; yet the results, if successful, would be munificent. The unenlightened peasants would be glad to exchange their platinum pieces for modern coin, probably be pleased enough to get half their face value even.

*Abstract from article entitled 'Among the Platinum Deposits of the Ural Range,' by L. Lodian, in the *Electrical Review* of January 5.

Radio-Activity.

Though the researches of Professor Thomson date from 1881, the actual starting point of the branch of physics which concerns itself specially with radio-activity was the discovery of M. Becquerel in 1896 that certain compounds of the rare metal uranium were able to emit rays which would darken a photographic plate, in the entire absence of anything corresponding to ordinary light-rays. This led to the work of Madame Curie on the waste products of uranium ores, from which she finally succeeded in extracting some minute portions of a salt which was many thousand times more active than the original uranium salt. This is now believed to be a compound—usually the chloride or bromide—of a new element called radium. It proved to have a singularly important property, which has equipped investigators with a new method of research, surpassing in delicacy even that in which the spectroscope is used. The rays emitted by radio-active bodies ionise the air through which they pass, and thus make it a conductor of electricity. Consequently a charged electroscope loses its charge as soon as a minute portion of any radium salt is brought into its neighborhood. This test can be made amazingly delicate, and has enabled us to learn a wonderful deal about the properties of radium compounds, although the largest quantity of them with which any investigator has yet been able to work is less than a grain. Professor Rutherford has shown that a radium compound is continually emitting three kinds of rays that have a wonderful power of penetrating ordinary matter. One kind, known as the Alpha rays, consists of a stream of material particles which are on good grounds believed to be atoms of the rare gas helium, which the spectroscope long ago showed to exist in the sun's atmosphere, but which was only discovered on the earth by Ramsay in 1895. The Beta rays are also a stream of material particles, but far smaller than any known atom; they are probably detached electrons, or units of negative electricity. The Gamma rays are true ether waves, akin to the Röntgen rays. In the act of emitting these radiations the atom of radium is, of course, losing a portion of its matter. This is the kernel of the great discovery that a true atom is able to break up into smaller particles, and therefore that it must consist of some arrangement of such particles, which—and not the atoms—are the true unit of matter. In losing its electrons an atom is converted into an entirely different atom, which has quite different chemical and physical properties from those of the parent. Professor Rutherford has described these radio-active transformations. He is able to trace the successive degradation of the radium atom through at least six diverse stages, each produced by a loss of a definite number of electrons, until at length, as he believes, it ends as an atom of lead—one of the commonest and least active of metals. This is very different from the alchemist's dream of the transmutation of lead into gold, but it is at least as epoch-making a discovery. Only those who have studied the matter closely can appreciate the wonderful triumphs of manipulation and reasoning which have thus enabled our physicists to get inside the atom, and trace the motions of the infinitely small electrons which compose it. We are on the threshold of a complete revolution in our ideas as to the constitution of matter.—*The Spectator.*

Trade Conditions in the Transvaal.

Writing from Johannesburg, Special Agent Raymond F. Crist furnishes the following interesting report:

At Johannesburg, of course, gold mining is the backbone and mainstay of the population. The business of supplying the various equipments of the mines is influenced by the mining organizations or 'groups' to a large degree, and they throw the sales to their respective home manufacturers. Most of the mines are supported or dominated by English capital. Two groups are under German patronage, and invariably give preference to their people at home, while the sundry small and unattached mines and a few of the 'groups' are open, or partly open, to bidders from any country. Many of the American managers and superintendents of the mines have given place to Englishmen, so that the former no longer predominate. In fact, this condition is described as an American exodus, so rapidly are Americans leaving.

As the greatest influence toward promoting sales of our mining apparatus has been in these men, it can readily be seen that our goods will have to rely largely upon past reputation to bring future sales. That this will prove less and less effective may be deduced from a review of a few of the active influences operating to overcome the popularity enjoyed by American supplies and supplant it by an increased interest in British and Continental manufactures. Every sentiment of loyalty to Great Britain as the mother country is appealed to, and in addition the colonial governments set a pronounced example in support of these appeals, by awarding contracts of every nature — especially large ones — wherever by so doing it is not too offensive, to British manufacturers. In all municipal work the rule is to give the contracts to the mother country. An instance was cited to me where a difference of £12,000 in a contract had failed to throw it to American bidders, the contract going to England on a bid of £53,000 as against £41,000. In another case a smaller margin did not produce a different result. The difference was £300 only, but by specious statements these actions were justified. Both were on large municipal improvements, and in the first a policy of exploitation of South Africa for the benefit of England seems to be indicated.

In addition to the sentimental influence, there is another that is probably more far-reaching and effective. This is the system built up by English bankers, manufacturers, and exporters, and the South African importers and mine operators. The mines of South Africa are financed in great part by English manfacturers and bankers, the predominating number of shares being held by them. In addition, these people are also shareholders in the large export houses of England, which are financially affiliated with the importing houses of Johannesburg. With these influences at work it is evident that an easy commercial channel exists through which pass most of the goods for South Africa, as well as mining equipment. The same is true of all other goods, hence it explains the tremendous preponderance of British goods in this part of the world. The financial interests are thus enabled to collect dividends all along the line. From the sale of their manufactured products, commission on export, ditto on imports here, and dividends on mine earnings to interest on the money in the transactions passing through their banks, they net a pretty income on their various holdings. The same is true of German interests, with probably a more jealous guarding of their business.

This country holds out no Eldorado for American manufacturers at present. Business is moribund, save along the most conservative lines. Merchants confine themselves to the actual necessities. Stocks are being reduced and cut in every conceivable manner by the conservative and safe merchant. Others are going under, and have been for the past two years. Overstocking and an excessive number of merchants proportioned to the population have led to failures. Stock speculation on the part of everybody in 'wildcat' gold and diamond mines has taken away money for everything save the barest necessities, and in many instances reduced men to bankruptcy and poverty who two years ago counted their sterling in the many thousands. Scarcity of native labor and uncertainty of Chinese labor, together with the politics of the nonconformist conscience in England, have caused European capital to withhold support of investments partially developed. There are dozens of mines shut down, or working half-labor, which would undoubtedly yield good dividends if only supported with more capital. New mining equipment is not the order of the day; only supplies of parts, due to wear and tear, constitute the bulk of business on the Rand. Merchants of all classes are up in arms, and this means that a turn must come.

Commercial Paragraphs.

The San Francisco offices of the GENERAL ELECTRIC Co. are permanently located in the Union Trust Bdg.

ARTHUR KOPPEL COMPANY, of 66 Broad St., New York, have established a branch in San Francisco and carry a stock of rails, steel ties, and industrial railway material in general.

THE HEWITT MACHINERY Co., of San Francisco, are agents for the Flint-Lomax Electric & Mfg. Co., of Denver, Colo. They manufacture a useful 65-lb. hammer for mine blacksmith work.

THE LINK-BELT COMPANY, of Philadelphia, Chicago, and Indianapolis, has opened a branch office at 321 Ellicott Square Bdg., at Buffalo, New York, and is in a position to give personal attention to customers of its drive-chain department in Buffalo and neighboring territory of New York, Pennsylvania, and Ohio. The facilities of the company in the manufacture of the Renold silent and other forms of power-transmission chains are tendered through its representative, H. C. Minier.

The Davis Calyx Diamondless Core Drill, manufactured by the INGERSOLL-RAND Co., 11 Broadway, New York, is a prospecting drill producing cores from 1⅝ to 15 in. diam. from any depth to 6,000 ft. It does not use diamonds, but, it is claimed, has never found a material which it could not cut at a paying rate. The cost of the entire apparatus is often less than that of the diamonds alone where they are employed, and the cost of diamond maintenance and replacement is entirely eliminated. It gives a double record, depositing the cuttings successively as they occur and removing the core in convenient lengths. For ordinary materials a rotating toothed steel cutter is used, this having a chattering action instead of a smooth cut, and for the harder materials chilled steel shot are used as an abrading material, the action of which nothing can resist. The apparatus is built in different sizes—the smallest operated by hand and the largest requiring 20 or more horse-power and capable of removing cores of large diameter from a great depth.

Editorial.

AMERICAN mining men sojourning in London can get the MINING AND SCIENTIFIC PRESS from Leathwait & Simmons, 5 Birchin Lane, E. C. This firm also acts as our agent to receive subscriptions.

SVEN HEDIN, who has been exploring Thibet, has sent word that his expedition discovered many mountain ranges "and goldfields." This is important, if true.

IN THIS issue we publish an article of melancholy interest, for it is a posthumous contribution to metallurgy from T. S. Austin, who was one of the most successful smelter-managers in America and Mexico. To his brother, our friend the professor at the Michigan College of Mines, we owe this valuable transcript from experience. Others will apppear in succeeding issues of this paper.

THE VALUABLE article on mining practice by Mr. W. H. Storms, was prepared in reply to a direct request for information. Our page of 'Concentrates' represents the result of other intelligent questions. While the numerous queries that we receive entail a good deal of labor in their reply, and some of them may be useful only to the enquirer, yet, on the whole, we are glad to receive them, because they indicate what kind of information is in demand. As a rule, the answer to one man's inquiry is of direct benefit to several, and is of interest to many.

A STRAW shows the way the wind blows and many a sincere opinion is expressed in jest. It appears that someone on the Canadian Geological Survey has been guilty of some clever rhymes, to be found in the last issue of our friend *The Canadian Mining Review*, and among them we note the significant line

"C's the collapse when they cut the Keewatin."

Underneath this appears a mysterious intimation: "Nov. 4, 1906, Nipissing, $31.00; Nov. 4, 1908, Nipissing, $00.34." All of which suggests the prevailing opinion of the members of the Canadian Survey that when the veins of Cobalt penetrate through the Huronian into the Keewatin formation, things will happen.

ACCORDING to Cope Whitehouse, the Fayoum in Egypt (where an American scientific expedition is now sojourning) resembles the Salton Sink, in its origin, area, and depth. It was once a great backwater from the Nile; this was in 1700 B. C., and the conversion into fertile fields has given its 350,000 acres an official valuation of $400,000,000. Salton Sink owes its existence to the confluence of the Gila and Colorado rivers; the former strikes the latter at right angles, and by reason of a mutual check to their flow, the slackened currents deposited the sediment that has built a bank across the head of the

Gulf of California and diverted the waters of the Colorado. Should Salton Sink remain a large lake, it will improve the climate of that part of the country and induce fertility. Already it has increased the rainfall in the arid regions adjoining.

THEORIES CONCERNING secondary enrichment have been used cleverly by promoters to excuse poverty of ore and to fortify the promise of richness in depth. But it has remained for the 'fiscal agents' of a Nevada enterprise to explain a discrepancy in sampling by suggesting leaching action. Ore that assayed from $11 to $23 in August, 1905, was found in October, 1906, to yield only $1.20 to $3.60. No work had been done in the interval. In the prospectus the puzzling fact is referred to thus: "The difference in these assays from those of the year before, is accountable from the fact that the workings had been exposed to the weather, and values naturally had leached." This is an astonishing fact, if it be a fact—which it undoubtedly is not. The solubility of gold in surface waters is slight, and no such period of time as one year would accomplish anything. If it had, we should expect a rush of scientific men to the Lige Harris mine, at Bullfrog. No, it is not the marvelous operations of Nature, but the "ways that are dark" of men that will account for the anomaly. Either the samples were badly taken, or they were salted.

Telluride Ore in Nevada.

Although Tonopah and Goldfield are neighbors, as neighborhood is understood in a land of magnificent distances, and their ore occurrence is taken to be similar, it is a fact that there is a wide difference. Tonopah is primarily a silver camp, that is, the ratio of silver to gold is 100 to 1 in ounces, or 3 to 1 in value. At Goldfield the ore does not carry enough silver to part the gold; in the bonanza mineral the ratio is 8 to 1 in ounces, or 1 to 4 in value. In the lower grade stuff the small proportion of silver is even more pronounced.

Another matter of interest is the occurrence of tellurides. These occur in the bonanza ore of the Mohawk, for instance; the mineral is calaverite, the telluride of gold, which contains 44 per cent of the precious metal. It was first recognized as a mineral in Calaveras county, California, and since then it has been found as an ore at Kalgoorlie, Western Australia, and to a less extent at Cripple Creek, where sylvanite (a gold-silver telluride) is more common. In the rich mineral of the Combination mine, besides the native gold, there is gray copper in the form of an antimonial tetrahedrite, which has been mistaken for a telluride. It occurs in association with bornite. It is a notable fact that gold should exist as a telluride in three such phenomenally rich districts as Cripple Creek, Kalgoorlie, and Goldfield. The coincidence has gone far to remove the old prejudice against the association with telluride, which characterized several unsatisfactory ore deposits in Transylvania, Colorado, and New Zealand. Incidentally, referring to the simple test for a telluride by applying strong sulphuric acid to a bit of the suspected mineral, it is worth pointing out that this test should not be applied to a pulp sample, because the presence of iron (from pyrite) will obscure the ruby coloration. Try the experiment on a clean fragment of the mineral you think to be a telluride.

The Burlesque of Mining.

In the *New York Commercial* we read that Professor Samuel Aughey of the Smithsonian Institution, the United States Geological Survey, and the University of Nebraska, has just finished a tour in Nevada. In his report on the Lee district, Professor Aughey says that "most of the mines in this district show nothing on the surface. It is folly to expect to find values on the surface, and mining men need not expect to get them until depths of from 7 to 15 feet are reached." What a boon to the boosters! Now they can point to poverty at surface as proof of the real thing, the genuine Aughey grandmother lode! We expect to see this dictum of the professor quoted by every itinerant promoter, the qualifying sentence at the end being, of course, omitted. But, speaking seriously, we venture to advise the Smithsonian and the Survey to warn the members of their staff from making reports on mines and furnishing ammunition to pirates. Not many men devoted to purely academic pursuits are capable of judging a mine or sampling an orebody; in nine cases out of ten they make fools of themselves and stultify science. However, this episode of the professor is not the worst. We read in the *Daily Mining Record* that "the government has put the seal of approval upon the camp of Wellington, Nevada;" for has it not "issued an official pamphlet under the direction of the United States Geological Survey," in which "splendid mention is made of the district that was established by the Wellington Association," the last mentioned being an advertiser of shares that "will positively advance to 25 cents on February 15th." The report of the Survey only states that "connecting the larger veins are numerous quartz stringers, which course in all directions, *like promoters*, often containing crushed areas, *like deluded stockholders*." The words in italics are ours. But even this circus performance is not as bad as the "delirious trimmings" of certain pseudo-experts. One of them writes in the *Anaconda Standard*, the editor of which ought to know better, that at Greenwater "the lava flow becomes less and less apparent as we travel westward, and the eroded strata and geyser depositions of conglomerate (contain) hydrostatic andesite copper. Along the line of the ascending and descending waters is found an altered intrusive diorite. Iron in various forms seems to be so heavily associated with the altered diorite that a concensus of opinion considers (it) the original magma of the ore." It reads like geology, and yet it sounds like gibberish; it is inebriated balderdash. And stuff like this is published in the *Anaconda Standard*, the *Daily Mining Record*, and other papers that are supposed to illuminate those engaged in mining.

Next, we come to the opinion of the Colonel. We need not mention the name. "It is pay-ore from the grass roots," stated the Colonel (so says the Spokane *Chronicle*), "and we have literally mountains of it, vast in extent and some of it very rich. Our engineers tell us that we

have at least 50,000,000 tons of gold-bearing ore in sight. This wonderful property is on the South Yuba river in California. John Hays Hammond, the noted engineer and expert mineralogist, has acquired property below us which we believe inferior to ours, and yet Hammond recently declared that he has billions on his property. If he has one billion we surely have five billions." We doubt if Mr. Hammond would own to being an expert mineralogist, and we feel quite safe in denying on his behalf that he has a mine on the Yuba that contains billions. If he had, he would naturally make a present of it to the Guggenheims. Joking aside, the above is the sort of stuff that is published in a reputable journal, and is re-printed in a number of newspapers, even in the mining regions.

However, bad as the foregoing types of spoofery are, the most insiduous and the most injurious to legitimate mining, as it is to honest engineering, is the pseudomorph of science. Here, according to a Butte paper and the *New York Commercial*, is the report of Dr. Frederick Bass, one of the most eminent, etc., etc. From his doctorate we infer that he is also an officer of the U. S. Geological Survey, for that title is one of the distinctions (so we have been told) that the Survey confers on its employees. Speaking of Greenwater, where copper ore occurs in a sheeted rhyolite, Dr. Bass says that the submergence of the region (we quote verbatim, errors included), "with its secondary depositions, interrupted by volcanic eruptions and mass elevations, has been alternating up to a comparative recent time (probably miocene), as evidenced both by horizontal beds and tilted strata of calmanite or biborate of sodium found in various parts of the district, principally on the flanks of the shales, slates, and limestones — which, in places, also show distinctively the intercollations of volcanic rock (lava), thereby proving the successive alternating periods of submergence, upheavals, and volcanism." It is not nonsense, and yet it is not sense; it is geology drunk with mining speculation, and no longer able to do duty as science. It is the sort of jargon that is believed of those who sell shares for 10 cents that will rise to 25 cents before Friday next.

Finally, we quote from the voluminous literature that is sent out nowadays from the bucket shop, usually styled 'trust company' or 'bankers and brokers.' In referring to Mr. Lawson's recent vagaries in connection with Trinity stock, a circular (sent to us in the belief that we were among the great gullible), states: "The sympathy of many mining men, naturally enough, is with Mr. Lawson; for, as already pointed out, while they are not a unit that Trinity is intrinsically worth $65 and more per share, as Mr. Lawson loudly proclaims, they are still convinced that, so long as the public is enabled to get into a mining proposition at 10 and under and to dispose of it at 65 and higher, a general buying sentiment in mining shares will be created among thousands who have heretofore devoted their investment funds to ordinary investment issues. And in that way the mining interests of the country must benefit." The public is to buy at 10 and to sell at 65 — to whom? Will the brokers, who know that the stock is not "intrinsically worth" the higher figure, buy it? And if you buy at 40 and sell the stock for more than it is worth to someone even more 'easy', will not the difference between the real worth and the paper value of the stock represent a dead loss to him? And is it thus that "the mining interests of the country" are to be benefited? What rubbish! It is the semi-criminal class, the camp-followers of a beneficent industry, that will gain at the expense of the unwary. Poor geology, poor old mining, what things are done in your name!

The Deepest Gold Mining.

The distinction of the deepest gold mining still belongs to Bendigo, and it is pleasant to note that the past year was a prosperous one at that famous Australian mining centre. Owing to the fact that a close record is kept of the dividends and calls, it is possible to gauge the aggregate profit made by all the mines of the district. On an output of 225,099 ounces, the dividends paid were £246,254, and the calls (or assessments) £221,262, indicating that the net profit for 1906 was £25,000. This may seem a small result, but the fact is there are not many mining districts that can show, year after year, a balance on the right side for the sum of their operations. In most cases the money taken out of one mine offsets that which is put into another during the same period and many prosperous mining camps, if the account could be made up accurately, would exhibit a deficit. During 1906 the calls levied at Bendigo were heavier than at any time for thirty years, this fact being due to the costliness of deep mining in the case of half a dozen companies. The largest dividends were paid by four mines on a subordinate 'line of reef', called the Pyke and Moon, that is to say, not on the anticlinal axes celebrated for deep shafts. The ore of these successful properties came from workings ranging in depth from 900 to 1,900 feet. The New Chum 'line of reef', the anticlinal axis on which the deepest mines are situated, furnished only two dividend-paying companies, the ore coming from between 2,200 and 2,900 feet. The deepest mines do not appear on the dividend list. The New Chum Railway is crosscutting at 4,284 feet to connect with a winze from the 3,856-foot level, some pay-ore having been found in an exploratory cross-cut from the winze. The Lazarus mine is 3,617 feet deep, and "well mineralized stone" has been cut at that depth. Victoria Quartz, at 4,151 feet, found the top of a saddle that yielded 12 dwt. per ton for a while, but proved disappointing afterward. Work is in progress on the 4,254-foot level. On the whole, the evidence obtained is confirmatory of the opinion we have expressed on another occasion, that deep mining at Bendigo has gone too far and that the sentiment for deep sinking is not justified by the commercial results. Even the deep mines that are on the dividend list one year will be found on the call list next year, so that the real unprofitableness of mining below 3,000 feet is obscured. The sensible operators are those who are exploring the shallower ground within the area that has been proved to contain valuable ore deposits. Ore at 1,000 feet is more likely to be profitable than at 4,000 feet.

Personal.

W. L. AUSTIN is at Butte.

ANDRÉ P. GRIFFITHS is in Korea.

OLOF WENSTROM is at Mexico City.

HENRY F. LEFÉVRE has gone to Peru.

F. C. CARPENTER will go to Bolivia shortly.

FRANK ELMORE is expected in San Francisco.

J. H. CURLE has returned to London from Biarritz.

FRANK DRAKE visited San Francisco this week, from Bishop, California.

JAMES W. MALCOLMSON has his office now in the Bryant Bdg., at Kansas City.

CHARLES E. COXE is engineer to La Mona Mining Co., in Zacatecas, Mexico.

W. H. KNOWLES has opened an office at 644 Chamber of Commerce Bdg., Los Angeles.

A. D. BENTON is now manager for the Paymaster Con. Mines Co., at Tucson, Arizona.

ERNEST J. WELLSTED is now manager of the Kalgoorlie office of Bewick, Moreing & Co.

A. K. ADAMS has been appointed professor of geology in the New Mexico School of Mines.

H. W. BANGLE has resigned as superintendent of Los Grados mines, in Guerrero, Mexico.

W. H. EMMONS is engaged in geological work, for the U. S. Geological Survey, at Bullfrog, Nevada.

JOSEPH LUXON is the new superintendent of the Ivanpah Mammoth mines in San Bernardino county, California.

G. M. GOUYARD has been appointed consulting engineer to the Bonanza Belt Copper Co., of Johnstown, Arizona.

F. L. RANSOME, of the U. S. Geological Survey, has completed his geological investigations at Goldfield, Nevada.

H. C. HOOVER has gone on his periodical Australian tour, as representative of Bewick, Moreing & Co., London.

C. M. FUELLER, of Denver, has returned there from Marysvale, Utah, and is now at Toluca, Mexico, examining mines.

T. H. OXNAM has accepted the position of general manager for the Consolidated Arizona Smelting Co. at Humboldt.

J. E. MCALLISTER, smelter manager for the British Columbia Copper Co., is in Europe taking a well-earned holiday.

R. GILMAN BROWN, on becoming a resident of London, has ceased to represent Charleton, Dickinson & Co. at San Francisco.

ARTHUR L. WALKER has been elected a director of the American Smelters Securities Co., and a member of the executive council.

EDMUND B. KIRBY has been appointed manager for the Federal Lead Co., at Flat River, Mo., to succeed THOS. F. E. FITZGERALD, resigned.

W. A. HEYWOOD has accepted a position as smelter superintendent with the Spassky Copper Mines Co. in Siberia. He is now on his way to London.

EDWARD S. WIARD, of Wiard & Brown, Denver, has gone to Mexico on professional business connected with the American Smelters Securities Company.

FRANK H. PROBERT has gone to Corbin, Montana, as consulting engineer to the Boston Corbin Mining Company. In March he will go to Jalisco, Mexico.

H. VINCENT WALLACE, who recently returned from London to Nogales, is now on his way to Guanajuato, Mexico. He will proceed shortly to Durango.

EDWARD A. NIS has completed his professional work at Greenwater, Cal., and is on his way to Honduras, to be mine superintendent for the New York & Honduras Rosario Mining Company.

AMONG the geologists who have left the U. S. Geological Survey, by reason of the inadequate pay, are J. E. SPURR, G. H. GARRY, and W. H. WEED. The two former are with the Guggenheims, while Mr. Weed is with the Lewisohns.

EDGAR A. COLLINS, who has been in charge of the Combination Mines Co.'s property at Goldfield, Nevada, since it was purchased in 1903, has handed in his resignation. This resignation will take effect on March 1, when the active control of the property is taken over by the Goldfield Consolidated Mines Co. Mr. Collins has accepted the superintendency of the Montana Tonopah Mining Co., at Tonopah, and will enter upon his new duties in March.

L. VOGELSTEIN & Co., New York, give the following figures of German consumption of foreign copper for the months January to December, inclusive, in 1906.

	Tons.	
Imports of copper in December	10,017	
Exports " " " "	1,702	
Consumption	8,315	
Imports of copper January to November	120,753	
" " " " " December	10,017	
		130,770
Exports of copper January to November	9,513	
" " " " " December	1,702	
		11,215
Consumption of copper January to December		119,555

Out of this quantity 8,027 tons were imported from the United States during November.

Mining Summary.

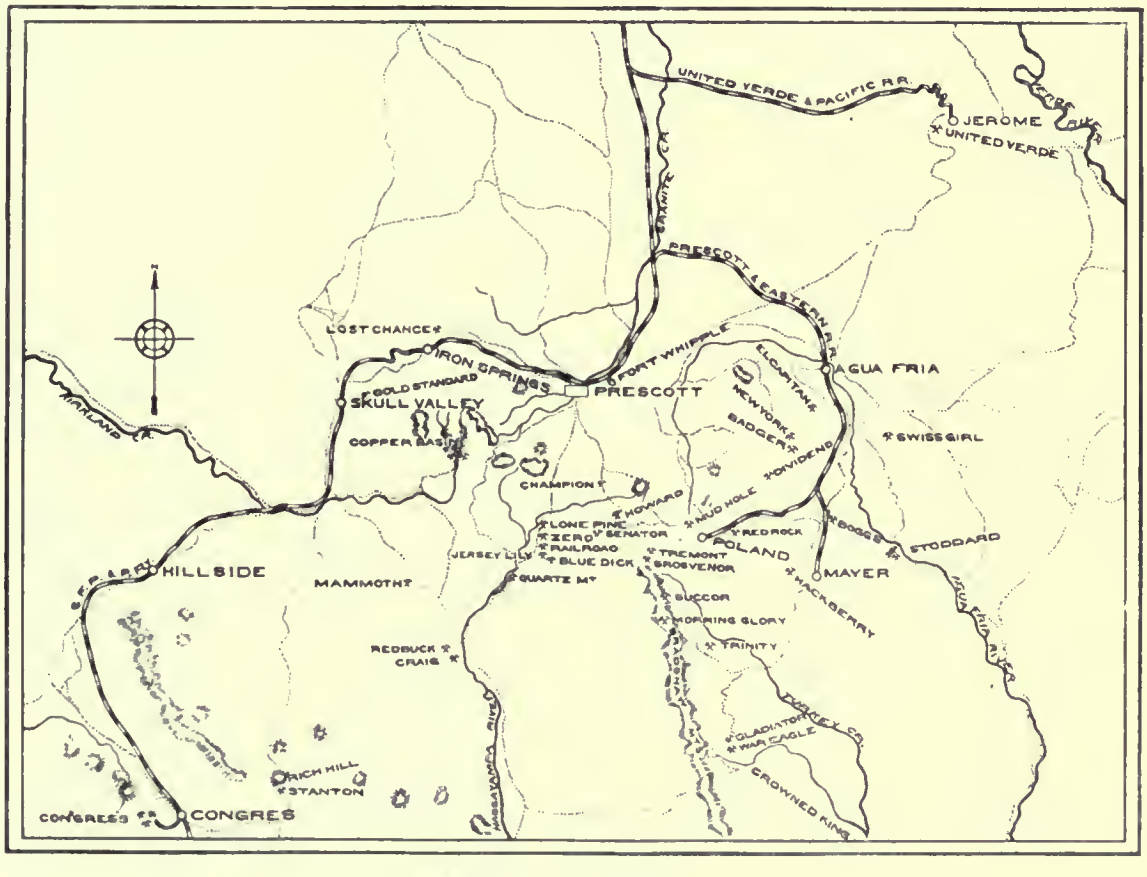
ALASKA.

Recent reports state that the diggings at the new Chandelar district are turning out to be rather disappointing. They are deeper than was first expected, and nothing of a sensational character has been struck as yet. Supplies are hard to get, and altogether it is not a desirable place to go, until more work has been done and more definite information is available.——The Latouche-Iron Mtn. copper mine, owned and operated by the Reynolds-Alaska company, at Horseshoe bay, is installing equipment that will enable it to produce 3,000 tons of ore per month. A townsite called Reynolds will be platted in the spring. Electric drills are employed at the property, power being derived from a water-fall 4,000 ft. from the mine. G. L. Banta is the superintendent.——A five-stamp mill will be erected at Nome, to be used as an experimental plant. A cyanide plant will be built in connection, and mill tests can be made in concentration also.——The Big Hurrah quartz mine at Solomon is employing about 40 men, and the mill is running continuously. A cross-cut is being driven on the 300-ft. level.——At Treadwell, the 240-mill and the Treadwell mine have started again. The Mexican and Ready Bullion started at the same time. During the shut-down, which lasted for nearly a month, many repairs have been made, and the plants are all in good shape. The fuel situation has been relieved by the arrival of a ship with 6,000 tons of coal; 120 stamps are to be added to the present 240-stamp mill at the Alaska-Mexican mine, and a new hoist will be installed at once. This addition will make 1,000 stamps in operation on Douglas Island, distributed through four mills, with a capacity of about 5,500 tons per day.——The Alaska Treasure company has completed its mill on Nevada creek, and will start operations about April 1.——In Silver Bow basin, about three miles east of Juneau, the Alaska-Perseverance company has nearly completed its 100-stamp mill, and underground work is progressing rapidly.

ARIZONA.

COCHISE COUNTY.

Over 700 miners have been laid off in Bisbee. The Spray and Czar shafts of the Copper Queen Co. are idle. The reason given to the men was that the shortage of fuel and lumber at this time makes it desirable to do repairing. It is reported as the general belief among the miners, however, that the situation is directly due to the attempt being made by the organizers of the Western Federation of Miners to make Bisbee a union camp. This organization has recently been perfected, and the local branch is known as Bisbee Local No. 160. The officers have declined to give the names of the leaders or the number of members. This action is causing a great deal of unfavorable comment, and local papers are pointing to the fact that there has never been any trouble in Bisbee, and that the miners there are receiving good wages, and have recently been given an increase by the operators. Many men are leaving the camp, and every train is crowded with men going to Cananea, Globe, and Tonopah. It is estimated that 375 men left in the two days succeeding the announcement of the lay-off. No further statement has been issued by the operators to account for the discharge of the men, and the situation is still a little puzzling.——Announcement has been made that the next regular dividend of the Calumet & Arizona will be paid March 20, at the rate of $5 per share. This is the biggest quarterly dividend ever paid by the company, and gives rise to the belief that the dividends will aggregate $20 per share in 1907. The capitalization of the company is 200,000 shares of a par value of $10 each, but shares sold as high as $195 on the Boston market last week. The mine is producing about 3,000,000 lb. of copper per month, and a sixth stack will soon be in operation at the smelter, which will increase the output materially. The company owns the Irish Mag, Buckeye, Senator, Gibraltar, Hope, and Wagner claims, the latter two having never been developed. A surplus of $5,000,000 is kept in the treasury.——Activity continues in the Paradise district. Over 500 ft. of work has been done on the Doran & Gallagher group.——The Bernoudy mine is looking well. Good ore has been cut in the east drift from the north cross-cut.



Map of a Part of Arizona.

MARICOPA COUNTY.

The litigation over the Fortuna mine, in the Cave Creek section, north of Phoenix, has been settled, and work will proceed under an entirely new management. Clarence E. Dresser will be the superintendent, and J. D. Thompson the manager for the company. The stockholders are New York and Pennsylvania people.

MOHAVE COUNTY.

The Golden Gem mill is running on dump ore and making a good grade of concentrate.—— Good ore is being mined by the Birmingham Leasing Co., on the Samoan property.—— Hoisting machinery has been ordered for the McKeeson mine, south of Kingman.——J. W. Thorn, of Philadelphia, has become interested in the Little Jack mine at Cerbat.—— Engineers have been examining the Maguire mine, three miles south of Kingman. The Bi-Metal claim of this property is a promising one.

PIMA COUNTY.

The Silver Bell camp is developing rapidly, and many properties are showing up well. The Paymaster camp is more active than ever before, and shipments of a carload of ore per day will soon be commenced.—— The Helvetia district has been entered by some of the larger copper companies, and it is rumored that the Helvetia Copper Co.'s property will be purchased by the Phelps-Dodge interests.—— Shipments are continued from the Twin Buttes property to the El Paso smelter. The company is planning the erection of a smelter at the property, and an extension of the railroad is talked of. This property has shipped 319 carloads of ore. New hoisting machinery has been installed and is working satisfactorily. Mr. Rose, formerly Mayor of Milwaukee, is heavily interested in the property.

CALIFORNIA.

AMADOR COUNTY.

The final decision of the Supreme Court of the United States has been handed down in the case of the Central and South Eureka mines. The Central Eureka, owned by the Coleman Bros., who used to operate the old Idaho mine in Grass Valley, gets the decision over the East Central Eureka mine. The point involved was: Has a mining claim, located prior to the act of 1872 and patented subsequent to that act, with convergent end lines, any extralateral rights. The Central's shaft, now down 2,400 ft., dips at 70°, and at a depth of about 1,500 ft., goes under the east side line of the claim. It was from below this point that over $1,000,000 was extracted. The end lines of the Central are not parallel, but converge toward one another, but the decision was given to this company, which settles a long and costly litigation.

ELDORADO COUNTY.

The Shaw mine has been transferred by Mrs. M. E. Morgan to the F. W. Barnard Co., of Beverly, Mass. This company also owns the Carson creek group, and the South Carolina mine at Angels. M. L. Green is the manager for this company. The property will be called the Morgan-Shaw mine, and is a large low-grade proposition, with a vein nearly 100 ft. wide. The new owners plan to erect a 20-stamp mill at once, which they will increase to 100 stamps, as development work progresses.

NEVADA COUNTY.

A good strike is reported on the Luzon gravel mine at American hill. This mine is on Fillmore ridge, between Wolf and Bear creeks. A rimrock tunnel has been run in for 250 ft., and a raise run 65 ft., which tapped the channel. Some new equipment will be ordered for the property at once.——Some rich gold quartz has been found in the Snow Point mine, belonging to Coppers & Hegarty, and situated in the vicinity of Moores flat. The ledge, which is about three feet wide, is worked through a tunnel.—Good progress is being made at the Gold Mound group of claims, on Deadman's flat. A gasoline hoist has been ordered.——The 10-stamp mill at the Conlin mine will be completed within a month. The mine has been forced to close down on account of the lack of fuel.——The Bear River Con. Tunnel Co. is making good headway in its tunnel on the north bank of the river. The ledge is growing wider, and the prospects are promising.

PLACER COUNTY.

The shaft of the old Iron mine is to be pumped out and sunk deeper. A new boiler and hoist are being put in place.——The last mill-run at the Bellevue mill averaged $40 per ton.——Twenty men are working at the Eclipse. The 10-stamp mill is running night and day. The owners are running the Cornucopia tunnel to tap the Enterprise, Friday, and Green mines at depth. An electric power line will probably be put in to run the Eclipse, and Gold Blossom mills.——Mining will soon begin in the Owl Creek district, between Spring Garden and Yankee Jims. The Rice location has recently been sold; it has a large vein carrying about $3 per ton. A mill was built on this property some 15 years ago, but as the capacity of the plant was small, and the ore uniformly low-grade, it was abandoned.

TRINITY COUNTY.

The French placer mines at Minersville have been bonded by G. H. Whitelaw, and work will soon commence. About 25 men are employed, and the property consists of 3,300 acres of promising ground.——The Bonanza King mine, near Trinity Center, continues to produce rich ore.

TUOLUMNE COUNTY.

(Special Correspondence).—The Rising Star group of mines, situated near Confidence, has been bonded to the Bagdad-Chase Gold Mining Co. The purchase price is $25,000, and is to be paid in two equal installments of $12,500 each, the first of which will be due in January, 1908, and the other one year later. Development work is to be commenced by March first.—— Shipments of ore from the Oak Hill mine, situated in the western part of the county, near La Grange, are being made regularly to the Mountain Copper Co.'s works at Vallejo. The ore carries 7% copper, $10 gold, and four ounces silver. The old shaft is being sunk to 300 ft. R. W. Alexander is superintendent.—— The Cocktail Gold Mining Co., composed of local people, has begun work at its gravel property, near Cocktail Hill, in the vicinity of Groveland. The prospects are said to be encouraging.—— An engine and compressor-building, and transformer-room are being erected at the Ida Klein mine, near Stent. When the machinery has been installed the prospect shaft, now 60 ft. deep, will be enlarged and used as the main working shaft. It is estimated that the dump contains 300 tons of $60 ore, besides which several tons of high-grade rock have been taken out in developmont work. —— Development work is in progress at the Mazeppa. A crew of 10 men is employed.—— At the Crystalline and Omega mines, of which C. W. Ayers is superintendent, 20 men are employed.—— Over 90 men are on the App mine payroll, and the 60-stamp mill is in operation day and night. Two valuable orebodies were recently uncovered, one on the 800 and the other on the 1,100-ft. level. W. A. Nevills, the owner, directs operations.——The Columbia mine, formerly known as the John Royal, has been sold to the Columbia M. & D. Co. for $18,000. The property is equipped with a Huntington mill and other machinery, and good orebodies have been developed.——The machinery for a 20-stamp mill has arrived at the Nonpareil mine and activity is predicted for the coming summer. A. P. Dron is superintendent.—— A rich copper discovery was made recently on government land near the Santa Ysabel mine. The vein is said to be eight feet wide. The property is to be known as the Green copper mine.—— The crew at the Longfellow has been increased, and the mill is in continuous operation.—— At the Mack mine there is much activity, and good ore is being milled.—— The Tuolumne Electric Co.'s power-plant, situated northeast of Groveland, on the Tuolumne river, is nearly completed, the only work unfinished being 8,000 ft. of flume, upon which progress is being made at the rate of 200 ft. per day. The company expects to have its plant in operation by April 15. The recent severe weather delayed the completion of the plant.

Tuolumne, Feb. 18.

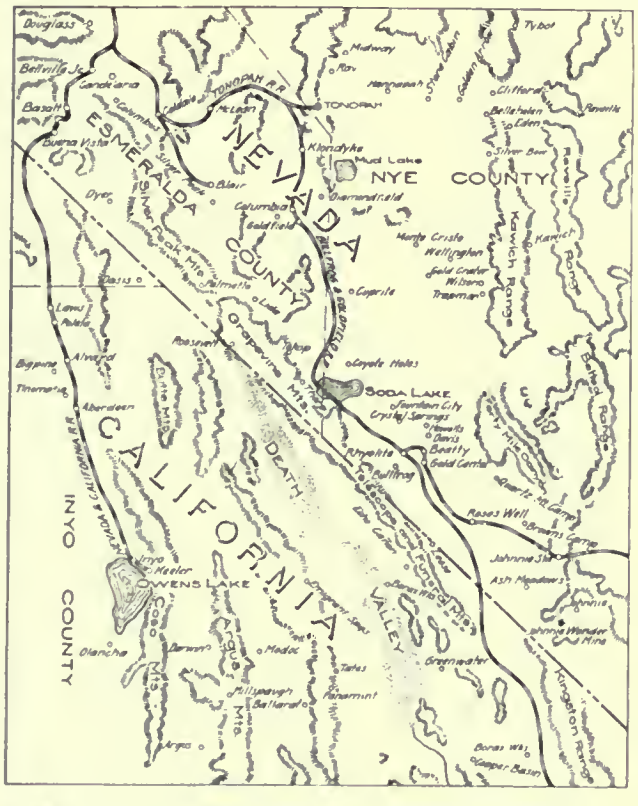
YUBA COUNTY.

French Corral, which was at one time a thriving hydraulic camp, is the scene of activity in quartz mining. A force of men has started work on the old Red Ledge copper mine which carries excellent values in copper, as well as gold

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—Advices received from London during the past few days state that a syndicate of capitalists is negotiating the purchase of the Waldorf mine and the Argentine Central Railroad, the consideration to be $3,400,000. The Waldorf company owns 1,800 acres of ground, situated in east and west Argentine districts, in upper Clear Creek county. Past development has consisted in driving the Wilcox adit for a distance of 4,000 ft. While driving, a number of veins have been interseeted. The Tobin adit embraces 6,000 ft. of underground workings, and on the various levels a body of ore measuring from two to eight feet in width is showing. The mines have been equipped with machinery, including two concentrating mills, the combined capacity of which is 250 tons per day. Shipments have been maintained for many months past. Henry Lowe and Rees C. Vidler are promoting the deal.—— The organization of the Commonwealth Power & Electric Co. means direct competition and reduced rates for power



Map of the New Mining Districts of Nevada and California.

in the counties of Clear Creek, Gilpin, Lake, Summit, and Routt. Articles of incorporation were filed a few days ago with the Secretary of State, and the capital stock is $2,000,000 with shares of the par value of $100 each. Valuable water rights have been secured on the Grand river, better known as the Gore cañon, and work upon the dams has been started. When completed, storage reservoirs for the generation of 20,000-h.p. in summer, and 8,000-h.p. during the winter months will result. Many contracts have been signed with operators in the various counties and at a price never heard of before in the mountain districts. It is expected to have the plant in operation inside of two years. Sufficient funds have been pledged, and a number of St. Louis capitalists are interested in the proposition.——It is reported that the holdings of the United-Hydro Electric Co. will be turned over to the Central Power Co., the consideration being $1,000,000. The United-Hydro Co. controls all the valuable water-rights of the Georgetown district, the plant being capable of furnishing 4,000 h.p. Business is transacted in Clear Creek and Gilpin counties, and the institution is one of the best paying propositions of this district.——A pool of Idaho Springs business men has taken a lease on a block of ground in the Bellevue-Hudson mine, situated on Columbia Mtn. A winze is being put down to make connection from the upper workings with the sixth, or tunnel, level. The block of ground is 600 ft. in length. ——Work is to be resumed in the Burns-Moore adit about the first of March. The bore is in 3,000 ft. and is penetrating the richest portion of the Cascade district.——The Lamartine mine continues to ship high-grade silver-lead ores. Rohner & Co., operating a big block of ground, have a bonanza streak and the production during the present year will be heavy.——Four tons of ore were shipped last week from the Pike-Rowe lease on the Little Mattie, which averaged $500 per ton in gold and silver. A pool of Idaho Springs men is backing the enterprise.——The Smuggler, on Brown Mtn., continues to show rich streaks of ore carrying silver and lead. A recent shipment of first-class ran $125 silver per ton. The second-class is shipped to the mills at Idaho Springs, where it is concentrated four into one. The concentrate averages $50 per ton. C. I. Burt of Silver Plume is the manager of this property.——The Homestake Gold M. & M. Co. has been incorporated with a capital of $1,000,000. The holdings are situated on Lincoln Mtn., in the new gold belt of upper Clear Creek. An adit is being driven to interseet a group of six claims at good depth.—— G. J. Hite has secured a bond and lease on 1,000 ft. of the Glendower lode, on Columbia Mtn. The workings are being cleaned out and re-timbered, preparatory to running a cross-cut to catch the ore-shoot which was lost a number of years ago.

Georgetown, Feb. 18.

LAKE COUNTY.

A contract has been let to sink the shaft of the New Monarch, on the Cleveland workings, another 150 ft. The shaft is already down 500 ft., and new pumps will be placed to take care of the increased flow of water. The New Monarch property comprises about 100 acres on the northwest slope of Little Ellen hill, and in the neighborhood of the Resurrection, Diamond group, and the Fortune and Penfield, now leased by the Yak company. This mine came into existence about 10 years ago, but has shipped a great deal of ore since then. James McDonald is the manager.—— A good body of ore has been found in an old 500-ft. shaft of the Jaybird property at the head of California gulch. A lease has been let, and ore will be shipped at once to the Arkansas Valley plant.—— The Mt. Harvard tunnel, in the main range at Riverside, is shipping to the smelter in Leadville. —— Work is being pushed at the Corona lease ground, adjoining the A. Y. & Minnie. The Corona shaft is down 350 ft., and fully 800 ft. of drifts stand open.

SAN JUAN COUNTY.

The old Laekawanna, on Mt. Kendall, is producing again, and two cars of ore have been shipped during the last month by lessees to the Durango smelter.—— The Hercules company has let a contract for a 200-ft. double-compartment raise, in the Little Dora mine.—— The Champion, on Sultan mountain, is working a good force of men in the mine and smelter.——The Champion No. 2 property, owned by the Detroit & Colorado company, on Sultan mountain, is shipping three or four cars per week to the Durango smelter. L. L. Haines is the manager.

IDAHO.

(Special Correspondence).—Mining men all over the Northwest are commending the members of the Idaho legislature in taking action aimed at what are termed wild cat schemes. The full text of the measure after the enacting clause is as follows: Section 1. Any person who knowingly makes or publishes in any way whatever, or permits to be so made or published, any book, prospectus, notice, report, statement, exhibit or other publication of or concerning the affairs, financial condition or property of any corporation, co-partnership or individual which said book, prospectus, notice, report, statement, exhibit or other publication shall contain any statement which is false or wilfully exaggerated or which is intended to give or which shall have a tendency to give a less or greater apparent value to the shares, bonds or property of said corporation, joint stock association, co-partnership or individual, or any part of said shares, bonds or property, than said shares, bonds or property or any part thereof, shall really and in fact possess, shall be deemed guilty of a felony and upon conviction

thereof shall be imprisoned for not more than 10 years or fined not more than $10,000 or shall suffer both said fine and imprisonment.

Boise, Feb. 16.

IDAHO COUNTY.

(Special Correspondence).—J. S. Danforth has sold his group of claims near Dixie for $30,000. The purchasers are New York capitalists. A 10-stamp mill has been ordered and a sawmill will be taken in next spring. The claims are on Crooked creek. The group consists of seven placer and five quartz claims, on which considerable development work has been done.——Andrew Prader and Alexander Zimmerman, of Spokane, who have been doing assessment work on the Union group of claims, three miles from the American Eagle, near Elk City, report a strike of ore in the mine. Samples brought from the property show free gold. The ore was encountered 90 ft. in the drift from the lower tunnel.——J. A. Coverly, owner of the Snowstorm mine on Red river in the Elk City district, has made a strike of gold and copper ore. The extent of the orebody has not been determined.

Spokane, Feb. 16.

SHOSHONE COUNTY.

(Special Correspondence).—The Cœur d'Alene district will add several dividend payers to the list this year. The Monitor mine, a copper-gold property, has declared its first dividend of one cent per share and is getting the property in shape to increase its output.——The Stewart gives promise of being a producer before long.——The Tamarack & Chesapeake has completed its ore-bin and is in shape to ship silver-lead ore.——Oom Paul has a large amount of development work yet to be done, but the company is steadily pushing development. Aside from these properties there are a score of others which are expected to show up with development.——Ben E. Hervey, of Spokane, has bought from Louis Bouldoc and others the Wonder group of five claims in the Evolution district, three miles from Osburn, for $10,000 and an agreement to drive a 1,000-ft. tunnel. A contract has been let for 200 ft. of the tunnel. The claims will be deeded to the Big Twenty Mining Co., which owns a group of 15 claims near the Wonder group. The Wonder group has been developed with a 425-ft. cross-cut and drift, which have opened a vein from 10 to 15 ft. wide, carrying a streak of ore from 6 to 20 in. wide which runs 10% lead and 33 oz. silver. The tunnel will be continued 150 ft. to get under the big dike.——John Doekton and associates, who own the Pilot mine, near Murray, will start a new tunnel on the property from above the level of Golden creek, 600 ft. below the portal of the present lowest tunnel. The tunnel will be run about 1,200 ft. to get under the present showing. ——W. W. Jones, of Sandpoint, has taken an option on the Snowstorm claim on Garfield bay for Leadville parties. It calls for a payment of $5,000 in 60 days, $10,000 the second year, $15,000 the third year, and a flat royalty of 15% on all ore shipped. The option was given by E. E. Teape, G. H. Hipke, D. M. Garrison, and Antony Van Hemert, joint owners. The Snowstorm lies next to the American Eagle, which is owned by Jones & Taylor. The claim is patented and has been opened in three places with exeellent showing. ——Articles of incorporation have been filed for the Spokane & Montana M. & M. Co. It properties are near Iron Mountain, Mont., and consist of nine claims. The vein on the surface is four feet wide. The officers are: M. Luxenburger, president, and W. R. McCraeken, treasurer. Work is progressing on the property and will be pushed continuously. ——Two important strikes were made last week at Snowstorm hill, on the Æolian and the Copper Plate. The Æolian lies in Deadman gulch, south of the Lucky Calumet, and the Copper Plate is in a gulch tributary to Deadman, south of the National and the Independent.——Mark Davis and J. K. Riordan are in San Franeisco arranging for machinery for the Montana-Heela Mining company, owned by Spokane men. A compressor-plant, steam hoist, and pumps are to be installed and then milling will begin. There has already been a great deal of work done on the property. The main working shaft is down 215 ft. and about 800 ft. of driving has been done. The property is a silver proposition. It will be a steady shipper as soon as machinery is installed.——The Success mine in Nine Mile creek, near Wallace, has been a good producer during the last four months, and will soon pay a dividend. During the last four months 5,715,600 lb. of zinc ore and 1,143,000 lb. of lead were taken out. The zinc averaged 45% net, and the lead ore averaged 60%. The mill is the first in the district to handle zinc ore. The property was formerly known as the 'Old Granite,' and it was supposed to be worked out.—— The Evolution mine has been leased to D. H. Robinson for five years. The terms call for the steady employment of men and a payment to the company of 10% of the net returns on all ore shipped during the first three years, and 12½% on all ore shipped thereafter till the expiration of the lease.——The Heela Mining Co. has declared its 43rd divldend, this time $20,000, which makes a total of $1,020,000 paid by the company.——The Tiger mine, at Burke, has been forced to close, owing to the coal and fuel shortage. The mine is one of the allied companies of the Federal company, and it is reported that other mines are in a similar position. The temporary bridge at St. Regis is completed and it is expected that relief will come before any further action is forced on the companies.

Spokane, Feb. 16.

NEVADA.

LINCOLN COUNTY.

The Ohio Mining Co., operating south of Crescent, has one of the best prospects in the Crescent district. Good ore has been struck in the cross-cut tunnel at a distance of 90 ft. The vein disclosed in the tunnel is two feet in width. Samples assayed as high as $32.40 in gold, with small silver values.——The Pride of the West group has been purchased by the Nevada-Crescent Mines Co., of Denver. This group consists of the Pride of the West, Pioneer, Butterknife, Edith, Nettie M., and the Legal Tender lode mining claims, situated three miles north of Crescent. Mr. Stanich, the manager, has been developing this property for the past year and has opened up some ore on the vein traversing the Pride of the West claim. Samples from the vein returned two ounces in gold and seven in silver. A 15-h.p. gasoline hoist has been ordered, to sink to water-level.——On the Quaker City group, F. G. Toberg has a force of men sinking a shaft and prospecting the surface. A good vein was encountered recently while doing the annual work, the ore being an iron-stained quartz, carrying free gold. There are five veins traversing this group.——C. N. White and associates are doing development work on the Comstock group of seven claims; Excelsior group adjoining the Double Standard of two claims; Florence group on Calico Hill of three claims; and the Creseent Giant group, south of Crescent. A vein of iron-stained quartz can be traced for 2,000 ft. on the Comstock group.——Systematic development work has been progressing on the Oro-Nevada under the supervision of Geo. H. Morrison. This property has opened up three feet of ore, and a shaft is being sunk on the vein.

Crescent, Feb. 8.

NYE COUNTY.

(Special Correspondence).—The directors of the Manhattan Consolidated Mining Co. are considering the construction of a mill. A proposition to put in a pipe-line from Jett cañon, nine miles distant has been before the public for several months and some work has been done. Measurements at the Consolidated property show that the mine is making about 9,000 gal. of water per day and this would supply a 10-stamp mill. Underground work has been confined to the 200-ft. level but as timber and other supplies come, sinking will be continued.——Shares from the treasury stock in the various companies subsidiary to the Dexter will soon be offered to the public. This company has worked principally on the Union No. 9 claim, where three leasing-shafts are down 160 ft., to water-level.——A recent decision clears the title to the Earl claim on Litigation hill, and the Manhattan Earl Co. has been incorporated.——The Manhattan Mayflower Co. has prospected its ground by several 50-ft. shafts and now proposes to sink a vertical shaft 300 ft. deep.——The Verdi reports finding sulphides on the 180-ft. level. Superior camp continues to attract local attention.

Manhattan, Feb. 13.

BRITISH COLUMBIA.

The fuel situation has continued to handicap all the boundary producers during the first half of the month, and the smelters are still running on reduced capacity, and mine and smelter men are losing a good many shifts. For the week ending Feb. 2, the Centre Star shipped 1,290 tons; Le Roi, 3,750: Le Roi No. 2, 360, and crushed none. At the Centre Star, the main shaft is rapidly approaching the 14 level, while the development on the Idaho continues, especially on the seventh and eighth levels. The dike has been crossed on the fourth level. Development in the War Eagle is in progress on the third, fifth, sixth, and eleventh levels. In the Iron Mask, ore is being taken from the fourth level. ——The decision of the Supreme Court has been handed down in connection with the appealed case of the Consolidated Mines Co., and Le Roi, which were convicted and fined about a year ago for allowing hoisting engineers to work more than eight hours in the 24, which was a violation of the Metalliferous Mines Inspection act of 1901. The superior court sustained the decision of the lower court, and the fines will have to be paid by the companies.——The Consolidated M. & S. Co., has declared a dividend of two and one-half per cent, making a total of 10% for 1906. This is a good record, in view of the fact that the Trail plant was unable to handle the full production. The company is in a very prosperous condition at this time, and a good record of production is expected for this year.——At a meeting of the Le Roi stockholders held in London on Feb. 4, a dividend of one shilling per share was declared, making a total of six shillings for 1906. A good surplus was held in the treasury. The profits of the year were $232,200, although $16,000 was spent in developing the Vancouver mine in the Slocan district. Owing to the increase in the output, the cost of mining has been reduced to $3.85 per dry ton, as compared to $4.22 and $4.45 for the two preceding years. The company has also acquired an interest in a copper property in Queensland. The directors passed resolutions of praise for the management.——The Granby has decided to install a system of trolley-haulage on the 400 level, doing away with the horses. The system will be similar to that in use in the No. 3 tunnel, except that the locomotives will be smaller. Diamond-drilling will be started in the Greyhound mine, at Deadwood camp, which is under bond to the Rathmullen Mines Co. A boiler and pump have been installed, and the shaft is being unwatered.——A station is being cut at the 220-ft. level of the Crescent mine, and the shaft will be continued for another 100 ft. After the new air-compressor is erected, shipments of ore will commence.——The Brooklyn mine of the Dominion Copper Co. has been forced to close down again on account of lack of coal. The property will not be started again until a steady supply of fuel is assured. ——The International Coal & Coke Co., of Coleman, Alberta, paid its first dividend a short time ago. It amounted to one per cent on the par value of the shares, the amount distributed being $28,000.——The Bay mine will ship a carload of ore soon, which is said to average about $1,000 per ton.

MEXICO.

CHIHUAHUA.

It is believed that the A. S. & R. Co. will blow in its new smelter in Chihuahua not later than October. The capacity of the plant will be 800 tons per 24 hours.——It is reported that L. Vogelstein & Co. of New York are considering the erection of a smelter at Jiminez, taking over the concession granted to J. F. Johnston of Parral.——The Parral Power & Reduction Co. now has its first unit of 1,500 h.p. ready for operation, with transmission lines into the mines at Minas Nuevas and the mill of the Parral Milling Co.——The roadbed for the railroad from the Cigarrerro mine at Almoloya, to Baca station on the Parral branch of the Mexican Central railroad, has been completed, and track-laying will commence at once. A 25-ton Shay locomotive has been ordered. The Cigarrerro company has decided to run a 4,000-ft. tunnel into the mountain, from the south, this to be the main tunnel for both mines.——The Uruachic Mining & Smelting Co. of Glasgow, Scotland, is to construct a wood-burning reverberatory furnace in the Ocampo district. This will treat the ores of the company and also do some custom work. H. D. Boddington is the manager for the company.——Joaquin Chavez brought the result of the last clean-up at the Dolores mine to Chihuahua. This was the December output, namely, 40 bars valued at $42,000.——A recent shipment of eight carloads of ore from the Josefina group of claims at Sta. Eulalia, gave returns of 90 oz. silver per ton. The orebody was encountered at a depth of 104 ft.; S. G. Burn is the manager.——John R. Roslyn of New York has purchased the San Francisco mine, of 50 pertenencias, in the Aguazoquete district, and will start work at once. The ore carries silver, lead, and copper.——It is reported that the Mexican National Dynamite Co. is contemplating the erection of a second factory, of the same capacity as the one now operating at La Tinaja, Durango.——The Socorro mines, near Sahuayacro in the Ocampo district, have been taken over by the International Gold Mines Co., a corporation of St. Louis.——The Minas Tecolotes y Anexas at Santa Barbara are running one 250-ton unit of their new plant, and it is expected that the remainder of the plant will soon be completed.

GUANAJUATO.

William B. Smith and W. H. Osborne, of New York City, have organized the San Cayetano Tunnel Mines Co., to take over the San Cayetano group of properties in La Luz district of Guanajuato. These properties have been in the possession of the United Mexican Mines Association Ltd. of London since 1814 and have been among the largest producers of this celebrated silver camp. The tract consists of 750 acres, embracing 19 different mines. F. P. Rawle, and W. M. Wiley, of New York City, conducted the negotiations on behalf of the San Cayetano Tunnel Mines Co., the United Mexican Mines Association Ltd. being represented by L. Maurice Cockerell.——W. H. Osborne, L. M. Cockerell, and W. M. Wiley are leaving for Guanajuato to effect the transfer of the properties, after which active operations will be begun at once. It is understood that W. M. Wiley will temporarily assume the presidency of the company.

The Mexican Milling & Transportation Co. has been organized in Guanajuato to build and operate a belt-line railroad and engage in custom milling. The belt-line is designed to connect with the Mexican Central, and reach every mine and mill of importance in the district. The company has arranged to take over the mines and mill of the San Prospero company, which latter is now crushing and cyaniding about 130 tons per day; and also the 50-ton custom-mill of the Nayal Milling Co. In addition, the company will build a mill of 200-ton capacity at Santa Ana, and one of 100-ton capacity in the Santa Rosa camp, and increase the Nayal mill to 100 tons capacity. Thus the company will have a daily milling capacity of about 500 tons.

The annual meeting of the Mexican Mining Co. was held in Pittsburg on Jan. 18, and C. C. Auld was elected president. A favorable report was presented, and a mill is to be erected.

JALISCO.

A good body of ore running better than $2,000 per ton has been encountered in driving on the 280-ft. level of El Favor mine in the Hostotipaquillo district. This drift was driven east from the central winze, which is being converted into a working shaft. This property was purchased by Makeever Bros., of New York, in June, 1906.—— The old Mataraña mine, in the Mascota district, has been taken over by American interests, represented by E. J. Callahan. This mine was bonded some time ago to L. C. Malone of the Santa Lucia Mining Co., and his rights have been transferred to Mr. Callahan. This property is on Espiritu Santo mountain, about 60 miles west of Ameca. It was opened by a Spanish family named Medina, and is said to have produced $7,000,000 in gold and silver.

SONORA.

The Sonora Quartz Mines Development Co. is operating La Yaqui and El Tiro mines, at La Yaqui, in the Altar district of Sonora. G. W. Tantan is the superintendent.—— The Tecoripa Mining Co., recently organized in Texas, has taken over the Providencia group of mines at Tecoripa, in the Hermosillo district

Special Correspondence.

Salt Lake, Utah.

Shipments from Tintic.—The New Smelter.—Consolidation of Properties.—Improved Milling Plants.—A Strike at Alta.—Daly West Report.—Heinze Negotiating for the Silver King.

The ore and bullion settlements reported last week through Salt Lake banks amounted to $824,200. The ore shipments from the Tintic mining district last week amounted to 132 carloads, the shipping mines and respective amounts being: Ajax, 2; Beck Tunnel, 11; Bullion Beck, 5; Centennial Eureka, 49; Eagle & Blue Bell, 2; Eureka Hill, 3; Gemini, 5; Godiva, 1; Grand Central, 5; Laclede, 1; Mammoth, 13; May Day, 6; Ridge & Valley, 3; Scranton, 6; Swansea, 4; Tintic Iron, 5; Uncle Sam, 3; Victoria 3; Yankee Con., 4 carloads.

Negotiations are pending for a consolidation of the Star Consolidated and Black Jack, with a possibility of the Lower Mammoth going into the merger. All these mines are situated in the Tintic district. The Tintic Smelting Co. is preparing to let contracts for the equipment to be used in the lead smelter to be built near Eureka. Simultaneously with the beginning of this work the Eureka Railway Co., a subsidiary organization, will start grading on the railroad that is to connect the smelter with the principal mines of the district.——The new hoisting equipment recently purchased for the Lower Mammoth mine will be ready for operation before the close of the week, when ore shipments amounting to 100 tons per day will begin.

With the exception of a ratification by the shareholders of each company, a consolidation of the Bingham Central and Bingham Standard Copper mines at Bingham has been effected. Samuel Newhouse is president of both corporations.

Arrangements for a consolidation of the Copper Glance and Illinois mines are also practically concluded. They will form the basis of the organization of the Bingham Amalgamated Copper Co.——The Utah Apex Mining Co. is marketing about 100 tons of ore per day that brings from $18 to $20 per ton. The tramway recently installed has proved satisfactory.——The enlargement of the mill of the New England Gold & Copper Co. is progressing favorably. Recent developments in the mine are of a most encouraging character. Work is confined to the opening of the orebodies below the tunnel-level.——Some alterations are being made in the equipment of the Last Chance mine. Heretofore, it is said, the plant has not been making a good saving.——Ore transportation from the mines of Bingham continues unsatisfactory, officials of the Rio Grande Western still complaining of a lack of equipment to handle the traffic.

At Alta the Emma Copper Co. has cut the contact vein toward which the main tunnel has been driven, exposing carbonate ore to the width of 30 ft. A winze is being sunk and is expected to encounter the sulphide zone within 100 ft.——The Albion Mining Co. will soon build a mill. The mine owned by this company has been systematically developed and in the spring steady shipments of high-grade ore will be commenced. William Hatfield of Provo is manager.——The Continental Alta tramway is out of commission on account of being disabled by snowslides.

The annual meeting of the shareholders of the Daly-West Mining Co. resulted in the retention of the retiring officers; they are J. E. Bamberger, president; W. H. Dickson, vice-president; W. S. McCornick, treasurer; who, with F. J. Hagenbarth and Lazzard Kahn, the latter of Cincinnati, constitute the board of directors. The financial statement shows that on December 31 the company had on hand $411,886. There was received during 1906, $1,013,448 from the sale of concentrate and $9,928 from miscellaneous sources. The disbursements, including $432,000 paid out in dividends, amounted to $983,952. A total of 14,492 wet tons of first-class and 64,344 tons of second-class ore were produced. The company has paid all told $5,449,000 in dividends.——Negotiations are pending between F. Augustus Heinze and Keith & Kearns, who control the Silver King mine at Park City. It is believed here that the result will be the transfer of control. An examination of the Silver King was recently made by Mr. Heinze's engineers.

Cripple Creek, Colorado.

Strike in the Findley.—Pumping on Battle Mtn.—The Thompson is Leased.—Low-Grade Ore Treatment.—Fire at the Vindicator.

The rich vein of ore recently encountered on the tenth, or 875-ft. level of the Findley mine, on Bull hill, has been cut at greater depth on the eleventh level. Assays as high as $400 per ton have been obtained, and the ore when shipped is expected to give returns around two ounces per ton. On the tenth level the orebody has been proved up for a width of 20 ft., and it is an entirely new one in the history of the mine.—— Is is rumored that negotiations are pending for the united and systematic handling of the water situation in the mines located on Battle Mtn. The scheme consists of pumping at one of the deep shafts of that locality, either the Gold Coin or the Stratton's Independence No. 1. The latter being the deeper of the two is looked upon with the most favor. The cost would be distributed between the mines that would be benefited by this scheme, consisting of the Portland, Ajax, Strong, Independence, and Granite.

A lease has been granted on the Thompson mine of the Elkton Co. to the Western Investment Co. Machinery is being moved on to the ground, and air-drills will be put to work on the upper levels of the mine. The ore averages about an ounce in gold and should give fair profits at the present rates of freight and treatment. This property was formerly under lease to James Wright, who took out some fair-grade ore.

During the month of January 100 tons of dump ore were shipped to the Wishbone mill from the Mountain Beauty on Bull hill. Returns around $7 per ton were obtained by the lessees, Blanchard & Sellers. The milling company agreed to pay the lessees as their share of the profits, all over $5 per ton, they themselves trusting to the economy of their process to treat the stuff at a figure within the $5 margin.——Sinking has been resumed by the Mines Leasing Co. in the Johnson shaft on the north end of the Dante property on Bull hill. Work will be continued until the 500-ft. mark has been reached.

On January 14 the compressor and boiler-rooms and a part of the engine-room at the Hull City Placer mine of the Vindicator Consolidated Gold Mining Co. were destroyed by fire, the origin of which has not been determined. The men in the mine at the time were notified of the danger and were brought to the surface through Vindicator No. 1 shaft. Owing to the buildings being wooden structures the fire spread rapidly and was only with difficulty overcome. The output of the mine will be cut off until the buildings can be replaced.——Two cars of ore have been shipped this week from the Index mine on Gold hill. The ore was obtained at a depth of 365 ft. and gave returns around $40. Operations are also being carried on in a winze below the 700-ft. level, which is now down to a depth of 58 ft. The ore, running about an ounce and a half, is raised to the surface level by an electric hoist and trammed to the main shaft.

Toronto, Canada.

Shipments from Cobalt.—Taxation of Mines.—Bounties for Smelting.—News from Cobalt.—Several Rich Strikes.—Another Railroad.

Shipments of Cobalt ore for the week ended Feb. 9 amounted to 220 tons from the following mines: La Rose, 58 tons; Nipissing, 52; Kerr Lake (Jacobs), 36; O'Brien, 33; Coniagas, 22; Cobalt Central, 16 tons.

Frank Cochrane, the Minister of Lands, Forests & Mines, on February 13 introduced into the Provincial Legislature bills providing for the taxation of mines and mineral lands, and for the encouragement of the smelting and refining of ores in the Province. The first measure puts an acreage tax on all mining lands in unorganized territory, and a tax on the yearly profits of all working mines, whether in organized or unorganized territory. This tax will not apply in cases where the yearly profits are less than $10,000. The amount of the tax is not stated in the bill, as the details will be perfected later. The bill to encourage the refining of metals empowers the Government to pay bounties as follows: On refined nickel or the nickel content of nickel oxide, 6c. per lb., aggregate bounty per year not to exceed $60,000; on refined cobalt or cobalt content of cobalt oxide, 6c. per lb., aggregate bounty not to exceed $30,000; on refined copper or copper content of copper sulphate, 1½c. per lb. or on any copper product carrying at least 95% of metallic copper, ½c. per lb., aggregate bounty not to exceed $60,000; on white arsenic from mispickel ores, ½c. per lb., aggregate bounty not to exceed $15,000 per year. The bounties are to be payable for a period of five years, and if the sum appropriated is insufficient to satisfy all claims on the basis given, it is to be divided on a *pro rata* basis. The proposition to tax mines has aroused a good deal of opposition among mining men and should it be adopted, the impost will probably be a very modest one.

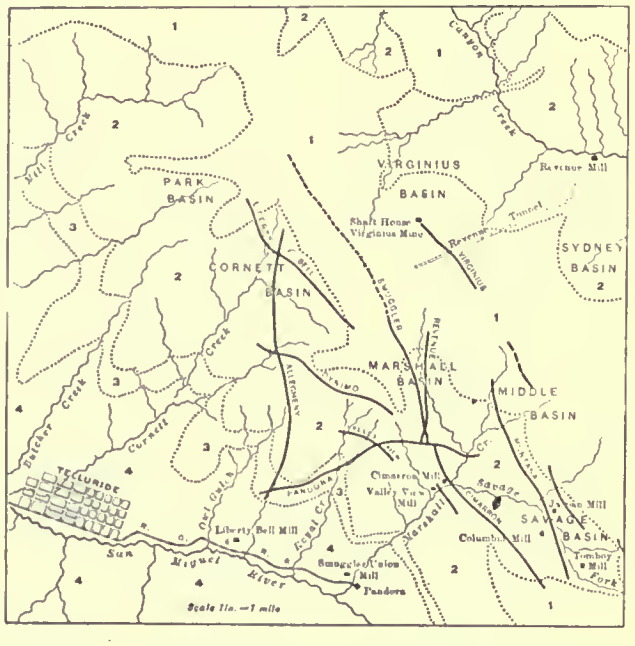
The Rochester Cobalt mine has purchased from the Rand-Jenekes Co. a plant comprising a 25-h.p. boiler, steam-drill, steam-hoist, and pump, which are being installed. Another rich vein has been discovered. Native silver was found in an open-cut on the main vein, which is about five inches wide and has been stripped for 250 ft. A shaft is down 18 ft., at which depth an assay was taken, showing 916 oz. silver per ton. Another rich vein has been uncovered some 50 ft. from the main vein running parallel to it, and about 2 ft. wide.——A strike of slab silver has been made at the 125-ft. level of the Nova Scotia mine. It is described as being richer than anything yet met with in the mine.——Silver ore with a showing of gold is reported as having been struck at the mine of the North Cobalt Silver Mining Co. at a depth of 40 ft.. This mine is two miles northwest of Cobalt, near the Green-Meehan.——Arrangements are being made for the sinking of an additional shaft on the property of the Lake George Co. to tap a vein containing native silver struck some time ago by diamond-drilling from a scow on the bed of Clear lake. The vein is thought to cross the Lake George location.——The work of lowering the level of Cobalt lake has been begun by the Cobalt Lake Mining Co. A dam has been thrown across and the water has been lowered several inches.——On one of the properties of the Cobalt Union Mines, Ltd., where systematic development is being carried on, a good vein of smaltite, rich in silver, has been discovered.

A charter has been received by American capitalists for the construction of a railroad up the Montreal river, to run through the Edison location and other properties, and probably as far as Evelyn lake, twenty miles up.—— The contract has been let for the construction of a branch of the Temiskaming & Northern Railway, running to Kerr lake, which will serve many of the leading mines. It will be about five miles in length.——Last week Dr. Hugo Von Hagen, president of the Hugo Von Hagen Exploration Co. of New York, J. T. Kirby, and Anthony Blum visited the Manitou Lake gold mining area, in which the company recently acquired large interests. They made an inspection of the Laurentian gold mine, and other properties, in order to make preliminary arrangements for development on an extensive scale.

Denver, Colorado.

The New Senator.—Treating Uranium Ore.—State Geologist.—Proposals for a State Survey.—Argument Against Appointing Professor, at State University.

The political turmoil incident to the electing of Mr. Simon Guggenheim as United States Senator has subsided, partly because of the tendency of the public mind to abandon a subject after having made it a nine days wonder, and partly because of Mr. Guggenheim's astute



Sketch Map of Telluride District, Colorado.

action in resigning his executive offices in the numerous large companies with which he is identified. Of course, this latter move is of no real significance, for Mr. Guggenheim still retains his interests in the companies, and by being relieved of any routine duties he is better enabled to aid them politically. But his action is well calculated to appeal to the unthinking, and thereby to restore the public confidence that was so badly shaken by the Senator-elect's inability to see why that eminently desirable virtue, gratitude, was not the only impelling force that induced the members of the Legislature to vote for his election after he had been so altruistic as to pay their election expenses. It is pleasing to observe, however, that class feeling has not entered into the consideration of the fitness of Mr. Guggenheim for his high position. Apparently he has not drawn the support of mining men because of his identification with mining interests, nor has the question of his race affected the opposition to him. This of itself is cheering, as another indication of the growing tendency in American public

life to consider public questions on their merits, without regard to prejudice, sectionalism, or race hatred.

It is interesting to note that the mill erected near the western border of San Miguel county to treat uranium ores is still in operation, after nearly a year of life. Such enterprises, being usually intended to exploit deposits that are problematical in their value and difficult to treat, making a produce that is fluctuating in its demand and value, rarely endure so long. It is now stated that a newly invented radium process is soon to be tried there. If it survives the strain of development it will have indeed demonstrated its strength and fitness to live. It is hard to refrain from expressing profound sympathy for any enterprise that is called upon to wrestle with a patented radium process.

The question of the State Geologist still continues to arouse discussion. Certain journals urge that the professor of geology at the State University should be the State Geologist, and that to take any other step is unwise. To lend force to their argument they point out that the department of geology at the University is, in its essential features, a place for geological research, and hence is perfectly adapted to conduct the study of the geological problems affecting the development of the mineral resources of the State. A moment's consideration suffices to exhibit the fallacy of such an argument. The nature of the department of geology at the State University is as stated, and because of this very fact it is to that degree unfitted for directing a State Geological Survey. Research in the way of pure science in the United States Geological Survey has always stood ready to do, and in fact has done all that has so far been accomplished. To attempt to duplicate on a smaller scale in connection with a State University and under the direction of a man whose abilities must necessarily be limited, work which in the hands of the Federal Survey can be carried out by the men who are the highest authorities in each particular branch of investigation, seems foolish enough. To the argument that the Federal Survey's work is so widespread that Colorado is hardly likely to receive as full attention as she deserves, are opposed the facts that in the past Colorado has received at least her full share of attention, and under the new organization of the Geological Survey is likely to receive even more in the future. In any case, the partial attention of the Federal Survey, with its larger resources and greater facilities for work, is likely to result in more accomplishment of real worth than the entire attention of a State survey, hampered by political affiliations.

The real need of the situation seems to be for a man of business ability, and with a competent knowledge of geology, mining, and metallurgy, who will be able to co-ordinate the work, organize the scattered forces, work in collaboration with the Government bureau in the larger phases of his work, and carry out himself such investigations as are of purely local interest, or of such special application, as not properly to come under the scope of the larger organization. Above all, he should be a man capable of considering the situation always from the standpoint of applied science.

Professors of geology are rarely noted for their business ability; and if they were in large degree capable of applying science to industry they would not be teaching geology. Therefore to make the professor at the State University also the State Geologist, rather than to choose for the position a man of business ability, broad general training and of experience in the practical application of geology to mining, is a move calculated to defeat the very end which it is sought to gain. But any organization is better than none at all, and if the elevating of the professor to the position of State Geologist is the only thing that can be done, by all means it should be done and so end the present chaotic situation.

Butte, Montana.

Operations in Full Swing.—Big Strike in the North Butte.—Also in the Anaconda at 2,400 Ft.— Minnie Healey Cuts Fine Orebody.— Butte & London.—North Butte Extension Co.— The Smelter Smoke Trouble.

All of the Butte producing mines are again running full blast, for the first time in two months, and the February output may slightly exceed that of January, when the copper production of the district was estimated at about 21,000,000 lb. Amalgamated officials say that the estimate was too high, as the Amalgamated mines were closed from one-third to one-half the time.

One of the biggest strikes ever made in this district is reported from the North Butte, which has cut a vein 28 ft. wide, fully half of which is copper glance, in the cross-cut driven from the 1,600-ft. level of the Jessie mine north to the Berlin claim. The clean ore assays 50% copper, and the strike is not only of material importance to the North Butte Co., but it is encouraging to a number of other new enterprises operating in that part of the district. The strike is farther north than any other copper vein yet developed to commercial importance. The company has given out no information regarding the strike, but it is understood to have been made in the Berlin claim itself. The cross-cut, which started at a depth of 1,600 ft., taps the vein at a depth of about 1,800 ft. in the Berlin. The Berlin vein, according to local opinion, runs in a slightly northeasterly direction and therefore will go through several of the claims of the North Butte Extension and the property of the Butte & London.

The East Butte has started three cross-cuts, one north from shaft No. 11 at the 400-ft. level to connect with a cross-cut started south from the 400 of the No. 1 shaft. It is expected that the connection will be made in about two months. Another cross-cut is being driven south from the 600 of No. 1 shaft and one north from that point. There are 21 known veins in the East Butte ground, all of which will be intersected by these cross-cuts between the two main shafts. There was some apprehension as to the quality of the ore that would be found at a depth of 600 ft., because there has been much talk about an imaginary iron cap that would be found at and above that point. The south cross-cut at the 600 has cut one vein about 80 ft. from the shaft and the vein was found wider than on the 400 and fully as rich. About four feet of it is first class ore, assaying 8% copper and better. The remainder of the 14-ft. vein is made up of concentrating ore.

The Anaconda Co. has cut the big Anaconda vein at a depth of 2,400 ft. in the Neversweat, the same depth at which it was cut about a year ago in the Anaconda mine. The orebody is of the same width, about 60 ft., and 40 ft. of it is nearly all copper glance, running 60% copper. Only two men are working on the ore and all that is taken out is sacked and sent to the smelter. With the big vein opened in both the Anaconda and Neversweat, there can be no doubt that it will also be found in the St. Lawrence mine of the Anaconda Co. and the Parrot mine of the Parrot Co.

The Coalition Co. has also cut into a splendid body of high-grade copper ore in the Minnie Healey mine, 100 ft. deeper than at any point at which the vein has yet been worked. While sinking a winze in the western portion of the mine to a depth of 1,300 ft. the orebody was encountered and some cross-cutting on it has been done. It has been sufficiently explored to give pretty good assurance that the ore is extensive. It is all first class,

assaying better than 8% copper. The Minnie Healey is developing into one of the best mines in the district.

Sinking has been resumed by the Butte & London Co., the pump having been installed at the 800-ft. station. The shaft will be continued until a depth of 1,500 ft. is reached, from which point cross-cuts will be run north and south.——The Butte-New York Co., which was organized by a few insiders of the Butte-Milwaukee Co. unknown to other stockholders, and which is directing the work on the Colonel Sellers and other properties of the old Butte-Milwaukee, is doing some rapid development work. A new hoisting engine has been placed on the Colonel Sellers, and a six-drill air-compressor is being installed. The shaft is now about 90 ft. deep. The Butte & Bacorn Co. has resumed sinking from the 500-ft. point of the Calumet shaft and it will be taken to a depth of 800 or 1,000 ft. before any more cross-cutting is done. In the 500 cross-cut two big veins were intersected, but at that depth they do not carry commercial ore.

The North Butte Extension Copper Mining Co., recently organized by G. A. Lauzier, of Butte, and financed by W. T. Van Brunt and associates, of New York, has three or four claims located on the extension of the Blackrock vein, which has been recognized by mining engineers as one of the big lodes of the Butte district. How-

Montana.

ever, the Blackrock has been opened only to 300 ft., to which depth it has yielded only silver ore. The Butte & Superior is engaged, however, in sinking the Blackrock shaft, and it is now nearly 600 ft. deep. At a depth of 800 ft. the vein will be explored. In the lower workings, on the 300-ft. level, some copper ore assaying as high as 3% was found while lessees were working the property before the organization of the Butte & Superior. The Blackrock vein has been traced across the Overman, Black Crow, Assay, and Occidental claims of the North Butte Extension Co. The latter will soon begin sinking a shaft on the Black Crow, for which active preliminary work has been going on during the past week. The North Butte Extension claims lie north and east of the Berlin group of the North Butte Co., from which fact it takes its name. The North Butte is sinking a shaft on the Berlin claim, and is also driving a long adit to that ground from the Jessie mine, situated some distance to the south. That part of the district is very active, and mining men look to the new companies to open some big mines there. Among those doing development and exploration work there are the Butte & Superior, Butte-Milwaukee, North Butte, Butte & London, the North Butte Extension companies, and W. A. Clark is sinking a shaft on one of his claims adjoining the Blackrock. The Lewisohns are also putting down a shaft on the Granite Mountain, near the North Butte mines.

It develops that six experts from the Agricultural Department at Washington have been detailed, by the direction of President Roosevelt, to assist the "smoke farmers" in the litigation against the Amalgamated, in which they are seeking several million dollars as damages and an injunction against the company to shut down the smelter The experts represent forestry, live stock, agriculture, etc. Some of them have already appeared in the trial of the case as witnesses for the farmers, and have admitted that they are participating in the litigation on orders from their superiors. It has developed that the President personally became interested after receiving a representative of the "smoke farmers," who bore a letter of introduction from a prominent Montana cattleman, a former acquaintance of Mr. Roosevelt on the plains, and that it was strongly represented to the President that the "farmers" were downtrodden victims of the Standard oil.

Calumet, Michigan.

Better Weather.— Ore Shipments Resumed.— More Purchases by Calumet & Hecla.— Work at the Nonesuch.

The storms which seriously interfered with railway service in the Lake Superior copper region during January and a few days in this month appear to be past, for the time being, at least, and the mines are again producing normally. During the recent storms snow covered railway tracks at some places to a depth of six feet, and shipments of rock to the stamp-mills was impossible. The companies owning and operating their own railroads fared better than those depending upon the larger roads. The Calumet & Hecla, and Quincy mining companies operate private railroads between their mines and stamp-mills. These lines were kept open during most of the bad weather, while mines depending upon the public roads were without facilities. The Allouez lost six days and the Centennial seven days in January.

Interests close to the Calumet & Hecla have purchased a tract of 228 acres of land bordering on Torch lake, and known as the Gregory property. It comprises three mill-sites formerly owned by the Centennial, Mayflower, and Old Colony companies. It is understood that the property has been acquired for La Salle company, a newly organized corporation, which is a consolidation of the Tecumseh, La Salle, Caldwell, and contiguous lands on the Kearsarge amygdaloid lode. La Salle company is controlled by the Calumet & Hecla, a majority of the stock outstanding in the former being in the treasury of the latter. Report is to the effect that La Salle company will erect a stamp-mill upon the site which has just changed hands. The property is opposite the mills of the Calumet & Hecla, on the other side of Torch lake, at Lake Linden, and is a most desirable one.

The Calumet & Hecla Mining Co. is continuing the exploration of the Nonesuch mine, in the Porcupine range of Ontonagon county, it having a three years' option upon the property. The Nonesuch has always been admitted to be a rich property, but the serious difficulty has been to save the copper. The metal is so finely dessimated throughout the sandstone-conglomerate lode traversing the property, and the copper of such a flaky nature, that it has been lost in the tailing. The Calumet & Hecla company recently completed the erection of a stamp-mill at the mine, and has been treating the ore for some time past. The result is understood to be satisfactory. Several barrels of the mineral have been shipped to the Calumet & Hecla smelters at Hubbell.

The Baltic lode is supposed to have been cut in the

drill-holes of the Lake Copper Co. in Ontonagon county, at a point 25 miles south of the Copper Range Con. mines. The cores show a lode 40 to 50 ft. wide, carrying a fair amount of copper. This discovery may prove important to the adjoining mines, namely, the Adventure, Mass, and Victoria.

Joplin, Missouri.

Output of Zinc and Lead Ore.—High Prices Are Maintained.—New Mills Started.—Several Strikes by Drilling.—New Prospecting Operations.—A Cave Leads to Discovery of Ore.

The highest price reported paid for zinc ore during the week ending February 2 was $52.50 per ton for one bin of ore from the Missouri Lead & Zinc Co's. land, and for the week ending February 9, $52 for one bin of ore from the Continental Zinc Co.'s land. The highest price paid for lead ore during the same period was $88.50 per ton for a few choice bins in both the Joplin and Webb City districts:

Shipments.	Zinc Ore Lb.	Lead Ore Lb.	Combined Value.
Week ending February 2	13,4 5,620	1,622,040	8376,820
" " " 9	12,003,510	1,532,740	347,917
Up to date	68,292,280	9,253,060	1,962,253
Same period last year	59,088,570	8,356,360	1,665,745
Increase	9,203,710	896,700	296,490

A party of stockholders of the Alice of Old Vincennes mine, situated at Chitwood, arrived in Joplin last Friday to witness the starting of the new 150-ton mill on their property. This was the first visit of some of the men to this region and they were surprised at the magnitude of the mining business. After seeing the mill started, they visited the underground workings of the mine and were pleased with the sight.——The frame-work of the new 250-ton mill on the Church & Mitchell property south of the Conner land at Prosperity is rapidly nearing completion. Prospecting on this property began a year ago but it was only recently that the shaft was sunk to a depth of 225 ft. and driving began, so as to open up some big orebodies, warranting the erection of the mill. There is a large pile of ore on top awaiting the completion of the mill. This promises to be one of the best producers in the district.

The Webb City Mining & Leasing Co., operating on the old Garrison land, is making extensive preparations for developing the property which was only recently acquired. They are enlarging the old mill from a 200-ton to a 250-ton plant. This is situated on the east portion of the lease. They have a new sludge-mill now in operation and are producing a quantity of ore from it. The erection of a 250-ton modern concentrating plant will be begun shortly on the west portion of the lease, where there is already a shaft down to the orebody. This property was at one time one of the big producers of the district, but the mining was done at a much more shallow depth than the present operations. J. F. Gallagher is manager.——The Seven-Up Mining Co., operating on the Missouri Zinc Fields lease at Webb City, has made a rich drill strike at a depth of 150 ft. A shaft will be sunk immediately.——H. W. Fullerton of Springfield, Ohio, and I. E. Raymond, of New York, who are associated with W. G. Koontz of Webb City, in a 20-acre lease on the Guinn land north of Webb City, have made a rich strike. The ore was found by drilling at a depth of 160 ft. and the cuttings show both lead and zinc ore.——At a depth of 205 ft. the orebody has been cut in the north shaft of the Trinity Lead & Zinc Co.'s property, near Duenweg. This is a new property under the management of J. P. Newell of Carthage, the stockholders being Eastern capitalists.

Some Joplin mining men are doing prospect work with a drill near Golden City in Barton county. It is not known at this time just what the outlook is in that part of the country, except that some lead is found on the surface.——The Chapman mine at Prosperity caved a few weeks ago and it has been discovered that the roof in one of the old drifts is practically a solid mass of ore and the work of removing this will be begun at once. This mine was one of the best producers in the district for several years, but at the time of the cave it was thought the orebody was about exhausted and had the accident not occurred, it is probable that the mine would have been abandoned.

Leadville, Colorado.

Camp Harrington.—Systematic Exploration.—Down Town Mining.—Increased Activity at Red Cliff.—The Upper Blue.—Progress a Kokomo.

For several months' past there has been unusual activity at Camp Harrington, the 'old camp' recently revived, six miles north of this city, on the Tennessee fork of the Arkansas river. Many years ago a large part of this district was prospected in a superficial way, with the result that no discoveries of importance were made. Many shallow shafts were sunk, but the mineral-bearing contact was not reached except in few cases. Developments of late prove the geological formations to resemble those common in the Leadville district proper, namely, porphyry, blue limestone, parting quartzite, and granite. The Lucy L. mine claims a record of more than $140,000, all of which came from a gash xein in the blue lime, but as the workings have not yet reached the contact, the consensus of opinion is that important orebodies will be opened up when the contact is reached. The Jennie June, a near neighbor to the Lucy L., is being developed in a substantial way by Colorado Springs parties, and within a few months the contact will be reached by the shaft now being sunk. Perhaps the most valuable, from the standpoint of determining the permanency and value of the camp, is the development work now being done on the Emma and Mabel placers, which embrace an area of more than 300 acres. An adit is being driven into Golden Gate hill from a point a few feet above the Cambrian quartzite. This adit is now in 170 ft., and it is the intention to raise at the 200-ft. point to the parting quartzite, unless the adit should cut it before reaching that distance. From this point a drift will be run north to cut the Lucy L. vein and south to cut the Jenny June vein. This enterprise is being promoted by the Harrington syndicate. The Leo shaft, near the head of California gulch, has been unwatered, and the drifts are being cleared for further development work. This shaft was sunk more than 20 years ago, and the new company, managed by W. S. Jones, controls 20 acres that it is proposed to develop through this shaft.

The Bohn shaft, on Toledo Ave., has been for years one of the most important of the 'down town' producers. This property, which is under lease to Leadville and Denver capitalists, has within the last few days let an important contract to Leadville miners to break the ore, which was formerly done by the company. There has been for some time more than 1,000 tons of rich silver-lead ore shipped monthly, and the results of late development work indicate a material increase in future shipments. The work of exploiting the lower workings has been much simplified and cheapened by complete drainage through the Penrose pumping plant.

Increased activity is noted among the Gillman properties above Red Cliff. A force of more than 40 men is now being employed on the Iron Mask alone, and shipments of ore will begin within a month. The orebodies of that district are similar in the character of their products to the zinc shoots of Leadville district proper. Although

the percentage of zinc is not high, the price of zinc at this time, coupled with the modern process of electrical separation, enables these ores to be shipped at a profit.

In the Upper Blue river district, northeast of Leadville, the principal properties in operation during the past year have been the Atlantic-Pacific, which ships its rich gold ores to Denver by way of Alma; the Senator, which has an adit over 4,000 ft. long, and shows several veins of milling ore; and the Wonderful-London, which is sinking a shaft for the ore-bearing contact. The shaft at 435 ft. is now in lime, and it is expected to encounter a blanket vein of ore underlying the lime.

Much interest centres in the Wilfley mill at Kokomo; the trial tests made with the new Wilfley roaster are reported to be successful. This furnace was designed to obviate the difficulties experienced from sintered ores, and is based upon the principle of the Stetefeldt furnace, well-known in the metallurgy of silver. The new 100-ton Breen mill is at last completed, and will add considerably to the force of men employed at Kokomo. The Kimberly company also has a force of 75 men rushing the building of the new 300-ton concentrator, which will be kept busy handling the low-grade ore, while the first-class ore from this property will be sent to the smelter at Leadville.

Johannesburg, Transvaal.

Brighter Outlook at Johannesburg.—Record Gold Output.—Details of Production.—An Alluvial Rush.—Indentured Chinese Stop Coming.—Progress in 1906.—Good Work of Tube-Mills.—Reduction in Costs.

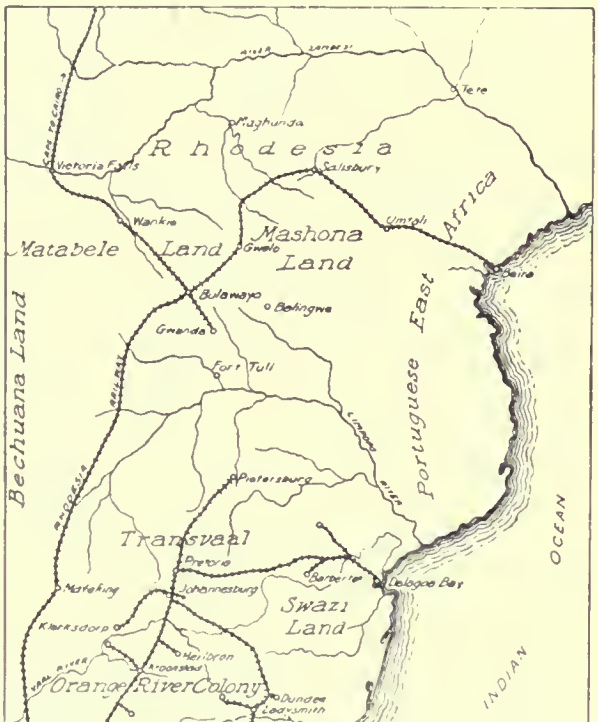
There appears to be less of gloom and more of hope in the situation here. Probably the results obtained by the gold mining industry in December have done a great deal to encourage the public. The total output of the Rand for December was declared at 529,521 oz., while the production of the rest of the country was 20,646 oz., making a grand total for the Transvaal of 550,167 oz., valued at £2,336,961. The December output makes a total of £24,492,288 as the value of the gold won in the Transvaal during the year 1906. It is highly improbable that either Australia or the United States will reach this figure, so that the Transvaal will easily be the premier gold producer of the world for 1906. There is an increase of 889,396 oz. over 1905.

During December there were at work in the Transvaal 8,410 stamps; of these 8,070 were on the Rand; and 340 in outside districts. There were 20 companies that declared an output of 10,000 oz. and over in December. The Simmer & Jack stands first on the list, with an output of 24,659 oz., valued at £104,744; next comes the Robinson mine, with an output of 20,768 oz., and third comes the Robinson Deep, with 20,211 oz. As usual there is a great variation on the different mines as regards the amount of waste rock sorted out. Only one mine, the Consolidated Langlaagte, put all its ore from the mine through the mill, making no attempt to discard the waste rock. The Princess Estate mine, on the other hand, where the reef is only one or two inches wide, and the stopes about thirty inches wide, reports a sorting percentage of 38 for December.

Some excitement was caused during the past month over alluvial gold. Several prospects have been found and syndicates formed to work them, but so far the outlook is not over bright for this phase of mining. Provided the gold is found in paying quantities, the difficulty in securing water will militate against the success of an alluvial enterprise. It is to be feared that this alluvial boom is more of the nature of a gamble and that very little will come of it.

During December the last batch of 2,000 coolies reached Durban from China. Until the policy of indentured labor is finally settled by the first Transvaal Parliament, no more Chinamen will come to the Rand. It is a significant fact that the organization for the recruiting of coolie labor in China is being kept up, showing that the leaders of the industry have every confidence that the new Parliament will decide in favor of the importation of indentured coolies. There were 52,889 indentured Chinamen in the employ of the mines on December 31, 1906. Could we be assured of a constant supply of 70,000 Chinamen, the Rand would be sufficiently supplied with unskilled labor, at least for the present, provided, of course, the same number of Kaffirs remain at work as at present.

The year 1906 proved to be the greatest in the history of the Rand. Were it not for the terrible apprehensions we passed through, due to the machinations of politicians, 1906 would stand as the red letter year of the Transvaal.



Map of the African Goldfields.

There was a distinct improvement in the extraction of gold; on some mines using tube-mills a total extraction of 94% was obtained. It seems that the tube-mills have bettered the extraction by at least 5%. The duty per stamp has also been greatly increased, one mine having reached a capacity of 8.5 tons per stamp in 24 hours. One of the most satisfactory features of 1906 was the reduction of working costs. This reduction has not been obtained by the sacrifice of efficiency, but by an all-round improvement in the working of the mines. The Chinese mines show up especially well in the question of working costs, on account of the increased efficiency of the coolies. On one large mine employing coolie labor the costs at first were 33s. per ton. On the same mine the working costs for 1906 were about 23s. 4d.

An unfortunate feature of 1906 was the enforced abandonment of work on developing mines, owing to the uncertainty of the unskilled labor supply. For political reasons principally, the eight-hour question became a pressing one during the year. A number of mines have adopted the eight-hour law, but it has not been an unqualified success, and on some mines the men are against the eight-hour day.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

PARAGENESIS is the general term used in rock nomenclature for the order of formation of associated minerals.

A SIX-INCH GRADE is one commonly used in sluices. This means six inches to the box 12 ft. long, or about a 4% grade.

THE solution used in sensitizing paper for blue-prints generally contains ferricyanide of potassium and ammonio-citrate of iron.

THE strength of an explosive is measured by its specific volume, the amount of gas it produces, its temperature, and the rapidity of its evolution.

ORTHOCLASE alters to muscovite or kaolin, upon being exposed to weathering influences. In the change, water and carbonic acid are the only chemicals required.

THE smelters in Shasta county, California, formerly obtained silicious ores locally, now the supply is deficient. The Mountain Copper Co. gets silicious ore from Nevada, the Mammoth gets it from southern Oregon.

IT has been proved experimentally that, as a rule, the length of the charge of explosive to be placed in the blasting-hole, should not exceed 8 to 12 times the diameter, for single holes. That is, a one-inch hole should never have more than 12 inches of explosive placed in it.

THE burning of oil as fuel will induce the rusting of iron, within the reach of the escaping gases. Crude oil contains 2½% sulphur—more of it than coal—and as it escapes in the form of sulphur di-oxide, accompanied or in the presence of water, it readily forms iron sulphate when in contact with iron.

THE aneroid barometer can be of service to a placer miner, as was proved by John R. Harvey, in Oregon. He kept the aneroid in his office, and, seeing it fall suddenly one day, he ordered his waste gates to be opened, and this was done just in time, for a storm wrecked all the other water systems in that part of the country.

THE St. Gothard tunnel is 48,840 ft. long, and was run from the two ends only. The face was broken for an area 26 by 20 ft., and was driven at the rate of 18 ft. per day, the work including the placing of 1,000 cu. ft. of timber and 300 tons of masonry per day, and the transportation of 750 tons of broken rock, 15 tons of lumber, and 300 tons of masonry.

A NEW incandescent lamp, called 'helion' on account of the resemblance of its spectrum to that of the sun, has been developed in the physical laboratories of Columbia University. The filament is not metallic, but can be operated with efficiency at a low temperature. A special carbon filament is used as a base, and upon it is deposited silicon. The lamp gives a very white light.

WROUGHT-IRON PIPES have the advantage over cast-iron in pliability, lightness, and toughness. They are easier to handle, and cheaper per foot notwithstanding that their cost per ton is about 25% greater. Also, they may be made in lengths of from 15 to 18 ft., instead of 12 ft., making fewer joints per mile, and possess the additional advantage that they may be bent through angles up to 25 degrees.

PEOPLE will make, without verification, statements that it is easy to verify; for instance, it is asserted that this or that ore contains tellurides. It is one of the easiest of tests to determine this fact. Put a bit of the mineral on a porcelain saucer and add a couple of drops of strong sulphuric acid. A ruby coloration indicates the presence of tellurium; the absence of it is proof conclusive that the mineral is not a telluride.

IN small compressors the inlet and outlet valves are generally controlled by springs; as the inlets are horizontal, the spring, in addition to overcoming the friction due to the weight of the valve, must be strong enough to close it sharply. That this spring tension is not a negligible quantity when multiplied by the area of the piston and its stroke, is proved when the inlet springs are even slightly tightened on an ungoverned compressor; the revolutions per minute at once decrease.

PURE nitro-glycerine is odorless, nearly colorless, and has a sweetish, burning taste. It is poisonous, even in very small quantities, and headaches commonly result from handling it. It is insoluble in water, takes fire at 306° F., and, if unconfined, burns harmlessly, unless heated to 380° F., which is the exploding point. The presence of surplus acid, not properly removed in the course of manufacture, renders the nitro-glycerine liable to spontaneous disintegration, which, by increasing the temperature, increases the danger of premature explosion.

IN cases where a large number of drills are used by a company, the cost of keeping them in repair may be as low as $12 per month per drill, provided they are operated by skilled men. This would be distributed about as follows: Supplies for repairs, $1.50; machinist labor, $8.50; and blacksmith labor, $1.75. Many companies figure that where few drills are operated and renewal parts are purchased from the manufacturers, the cost of repairs averages about 50c. per drill per shift. In South Africa, where each drill works two shifts per day, the cost of repairs is $300 per drill per year.

WITH the beginning of the present year, the Government internal revenue tax on denatured alcohol was removed, making the question of alcohol fuel one of immediate interest. The ordinary gasoline engine will not use alcohol economically, and probably the coming year will see new types of engines especially designed for this purpose, and an arrangement for the production of a denatured spirit at a price that will enable it to compete with gasoline. The alcohol possesses considerably less heat value, as compared with gasoline, but the efficiency of the engine may be increased in the case of the alcohol, by increasing the compression.

THE nitro-glycerine in dynamite freezes at 42 to 46°. When it is frozen it cannot be exploded by the ordinary caps used in blasting, but it is extremely sensitive to friction or to any breaking or cutting of the cartridge. Accidents are common in thawing dynamite. It should never be thawed by plunging the sticks into hot water, as the nitro-glycerine leaks out, and many accidents have resulted from re-heating water which has been used in a dynamite thawer. It is also unwise to hold the sticks over a hot body, for the purpose of thawing them, as the nitro-glycerine will leak out, and it is extremely sensitive then to shock and heat, and one drop falling even a short distance upon a hot object, will explode, and thus set off any dynamite that may be near. Low-grade dynamite, 40% and under, is safer than high-grade, as the base is not so thoroughly saturated with nitro-glycerine, and the sticks are not so apt to leak.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

The Sampling and Assaying of a Car of Bonanza Ore.

The Editor:

Sir—Much interest having been aroused by the recent shipment to the smelter of the Selby S. & L. Co., San Francisco, of the so-called "million dollar" car of ore, I thought it might be of interest to the readers of the MINING AND SCIENTIFIC PRESS to know how such a car of ore was sampled and assayed, and how closely the assays would agree. I have therefore obtained permission from the management of the Mohawk Mining Co. to publish the following data.

The ore came from the famous Hayes & Monette lease of the Mohawk mine at Goldfield, Nevada, and was shipped by Wells Fargo & Co. express, requiring three of the ordinary baggage cars to convey it to the smelter. It could, however, have been shipped in one of the modern freight cars, had its value permitted, as the total gross weight was only a few pounds in excess of 50 tons.

In sampling, the shipment was divided into ten lots of approximately five tons each, and each lot sampled according to the following method: The whole lot was passed through rolls crushing to pass a quarter-inch screen, then shoveled over and coned twice on a floor covered with iron plate in order to thoroughly mix. It was then cut down on riffles of the Brunton design to about one-fifth, or 2,000 lb. This was again crushed by rolls reducing to about 10 mesh, and again shoveled and coned twice. After this mixing it was divided by the riffles into two portions of 1,000 lb. each, and each of these again cut in two in the same manner, giving four samples of about 500 lb. weight. Each of these was treated as an independent sample, and was riffled down to about 20 to 25 lb. taken to the pulping room, dried and ground in a sample grinder to pass 100 mesh; from this four pulps were taken, one for the smelter, one for Hayes & Monette, and one for the Mohawk Mining Co., while the fourth pulp was set away for umpire in case of differences. There were, therefore, 16 pulp samples for each lot of five tons, of which 12 were assayed. The results all agreed so closely that no umpires were called for.

In assaying, the Selby smelter, of course, had its own assayers; Hayes & Monette brought with them Mr. Downer, of Downer Bros., Goldfield, who leased the laboratory of the James & Gray Co., of San Francisco, in order to do the work himself, while I represented the Mohawk Mining Co., running the assays in my own laboratory at Oakland. I failed to take copies of the assays on each pulp made by the other assayers, but I have tabulated below the averages of the four samples of each lot, which was the basis upon which settlement was made by the smelter. I may say that the checks on each pulp representing one of the four samples of the lot, checked as closely as these averages, and in many cases were within a few hundredths of an ounce. Occasionally one of the four pulps would vary materially from the other three, and this difference, while shown in the returns of each of the assayers, would disagree usually, much more than the differences on the other samples of that lot. This accounts for some of the greater differences, especially in lots 3,421 and 3,424, where both Selby and I found pulps from No. 3 and No. 2 samples, respectively, very much lower than the other samples. While Mr. Downer's returns on these samples were lower than on the others of these lots, still he did not have the differences that both Selby and I found, and which brought our averages much below his. On the individual samples of these lots Selby and I agreed quite closely, especially on the samples of lot 3,421, where our averages check within four-hundredths of an ounce.

Lot number.	Selby.		Downer.		King.	
	Gold. Oz.	Silver. Oz.	Gold. Oz.	Silver. Oz.	Gold. Oz.	Silver. Oz.
3,416	558.30	71.10	561.22	62.82	559.81	69.31
3,417	716.77	87.40	718.32	84.93	718.16	86.75
3,418	529.15	69.80	527.74	69.20	530.07	68.23
3,419	491.87	64.52	490.99	57.55	492.59	62.02
3,420	497.95	63.10	500.72	56.28	499.15	61.96
3,421	824.55	92.80	828.21	90.39	824.59	91.85
3,422	770.75	82.32	771.56	88.02	769.55	84.96
3,423	564.72	76.52	567.87	70.83	565.08	74.36
3,424	592.00	75.00	601.45	71.71	593.86	73.35
3,425	533.50	70.10	534.21	68.90	533.32	68.44
Average ...	607.956	75.266	610.229	72.063	608.618	74.123

Selby is lowest on gold six times; on silver once.
Downer " " " twice; " " seven times.
King " " " twice; " " twice.
Selby is highest on gold no times. on silver nine times.
Downer " " " eight "; " " once.
King " " " twice; " " none.

Selby and Downer check within one ounce twice, the closest being 0.71 gold; while four times it is greater than 3 oz., the greatest being 7.59 ounces.

Selby and King check within one ounce five times, the closest being 0.04 oz.; while in no case is the difference greater than 2 oz., the greatest being 1.86 ounce.

King and Downer check within one ounce twice, the closest being 0.16 oz.; four times the difference is greater than 2 oz., and twice it is greater than 3 oz., the greatest difference being 7.59 ounces.

In only one instance do all three check within one ounce, and four times do they check within 2 oz. This of course has reference to the gold.

In assaying the first few lots I used both ½ A. T. and ⅒ A. T. charges in crucibles, but as the quarters checked as closely as the tenths I adopted the quarter assay-ton charges for the rest, as the error would be multiplied more by the use of tenths. Notwithstanding that the gold is present almost entirely as a telluride, I experienced no difficulty in the cupellations, except that in the doré buttons, it was impossible to get 'feathers' on the cupel.

Selby, I believe, used tenths, and that may account for their slightly higher results on the silver, though Mr. Downer also ran tenths, and he is the lowest on the silver. He explains this by the furnace he was using, having a small muffle, fired by gas, and the manipulation of which he was not accustomed to. Selby used large muffle furnaces fired by coke, and I, a furnace of my own design, double muffle fired by gasoline, the lower muffle holding fourteen 20-gram crucibles, and the upper muffle for cupellation being 9 by 15 by 5¾ inches.

I used a very basic litharge flux, giving a gentle slow heat for 30 minutes and a high heat for 20 minutes, throwing down about a 25-gram lead button. Six fusions were run on each sample, four being alloyed in the crucible from which the gold was determined. Three times as much silver as there was gold present was used in alloying. The beads were treated as in the bullion assay, being rolled into cornets, and parted with two acids.

The checks on the different samples of the same lot were usually quite close, but occasionally one of the four samples would vary considerably from the other three, as shown in the following:

Lot number.	Sample 1.	Sample 2.	Sample 3.	Sample 4.
3,416	562.92	562.27	564.90	549.15
3,421	830.84	827.94	812.56	827.04

As remarked above, this difference was shown in the assays of the other assayers and corresponds with the same number of samples.

The checks in milligrams on the different buttons are interesting:

Lot No. 3,416 ....140.81; 141.12; 140.98; 143.73 being sample No. 1.
" " 137.24; 137.52; 137.10; 137.55 " " " 4.
" " 3,418 ....132.70; 132.68; 132.51; 132.15
" " 3,417 ....180.52; 180.90; 181.10; 180.84

Occasionally the beads would fail to agree within several milligrams on the first fusion, but upon repeating they would check, showing that it was due to faulty manipulation and not to spottiness of the ore.

Selby claims to have made correction for surcharge of silver in the parted buttons, which might account in part for the average difference between them and myself; they did not, however, correct for the cupel and slag losses which I found to be in cupel 0.4 oz. gold, and in the slag 0.05 oz. gold, or when calculated to the ton it would be 1.80 oz. gold. I, of course, did not correct for this either, as I knew Selby would not allow for it.

While the assays show that the total value of this shipment is less than a million dollars, yet it is well above $600,000, and I am told exceeds in richness that of any other shipment in the world for the same tonnage.

LOCHIEL M. KING.

1311 Franklin St., Oakland, Cal., February 11.

In Defence of Greenwater.

The Editor:

Sir—You will doubtless pardon my presumptiousness in daring to intercept your unfavorable editorial opinion on the great "Greenwater Country," but feeling assured that I have men at my back, who perhaps have collectively nearly as much gray matter in their cranium as the somewhat considered eratic Mr. James W. Abbott, I will venture to arouse your augmentive abilities.

Perhaps for your present consideration, it might serve the purpose of refuting the many absurd, unkind, ungentlemanly and unjust statements of Mr. Abbott, for me to inclose a recent contribution of mine to the "Anaconda Standard."

Pardon me for remarking, but you say Mr. Abbott is unprejudiced and a man of ability. After a careful perusal of his article I believe you are wrong. The venom of the cynic, disgruntled and unsociable man crops out in his almost every phrase.

Expecting your gentlemanly courtesy, in the reproduction of my article in answer to Mr. Abbott, I remain,

E. L. HEWS.

Greenwater, February 10.

(Here follows a portion of the article mentioned)

"In the whole record of mining history, no such prima facie evidence of an extensive fabulously rich deposit of the earth's precious metals has been revealed to man as the observation, investigation and development in the Greenwater mining district have shown. To the north is their environment of gold; to the west are their copper, borax and chemical deposits of Death valley; to the south and east and southeast and southwest are their copper, gold, silver and, perhaps, precious stones. The same ozone of God has combined with associate forces and with their almighty force disintegrated, changed and altered out of their original magma the various mineral depositions as they have in Butte and the universe. The geologist forsakes his theoretics of years. To classify is subject to a disputation, and he can only rely on the laboratory man to give him the truth or falsity of his deductions. The country traveled in coming from the great parent town of the desert mining of recent years, Tonopah, shows where at one time the blast furnaces of nature were at work. * * * The lava flow becomes less and less apparent as we travel westward, and the eroded strata and geyser depositions of conglomerate hydrostatic andesite copper. Oxide of iron stains many parts of the cappings, and to the newcomer the country looks decidedly promising. It has been my fortunate opportunity to traverse these hills and find that in a large part of the Greenwater mining district the copper-bearing appearance is general. Along the line of the ascending and descending waters is found an altered intrusive diorite."

[Except for correcting the spelling of Mr. Jas. W. Abbott's name, we publish Mr. Hews' letter exactly as received. If this is the best that can be said for Greenwater, it is in a bad way. We have not space for the whole of Mr. Hews' contribution to the *Anaconda Standard*, but we publish sufficient of it to indicate a curious familiarity with the purpose of the Almighty and a profound knowledge of the structure of the universe. What was the matter with the editor of the *Anaconda Standard*? —Editor.]

A Curious Occurrence of Copper.

The Editor:

Sir—In your issue of November 24, W. W. Rush writes of a 'curious occurrence of copper' in Alaska. It may interest some to know that a similar occurrence has been noted near Shingle Springs, in Eldorado county, California.

On a claim owned by C. F. Staver, Emmet Davies, and others, there is a belt of serpentine in the amphibolite, typical of that region. The serpentine carries as its sole mineral content fine flakes of bornite. There is no apparent alteration, and the bornite appears to be a primary ore. There are several old shafts on the property, it having been worked in the '60s, during the copper boom. The ore is similar wherever met with. During the past year this attracted the attention of several mining men of ability and experience. As a concentrating proposition, it lacks the usual iron sulphides. Perhaps others have noticed a similar occurrence.

C. Y. KNIGHT.

New York, February 11.

THE UNIVERSITY must be cosmopolitan in its composition and catholic in its range. Knowledge is only divorced from practice by a shallow philosophy, for no true learning is without its value in practical life. Literature gives not only a freemasonry of spirit and understanding, but a perpetual stimulus to the mind. History shows us morals writ large in the fate of nations, philosophy gives perspective and elevation. All alike give the student a sense of the unseen, of the things of the spirit, which add dignity to service, inspiration to work, purpose to suffering, a value, immeasurable and eternal, to the humblest of human lives. This is the true aim of University education, the training of the mind and character, not the turning out of so many experts in so many branches. Knowledge must be sought single-heartedly for its own sake, and not for its usefulness in the world, for it will fail of that usefulness if it is pursued in any narrow commercial spirit.—Henry Asquith.

THE chief reducing agents used in assaying, for reducing litharge to metallic lead in the crucible are: Argol; charcoal or coke or coal-dust; and flour or sugar. The amount to be used in the charge depends on the weight of the lead button that it is wished to produce. One gram of argol will reduce 5.45 grams of lead from 5.85 or more grams of PbO, when the argol is a pure bitartrate of potassium. But as it often contains carbonaceous matter, its reducing power may be from 7 to 9.5 grams lead to one of argol. One gram of charcoal will reduce 34.1 grams of lead, which in practice is found to range between 20 and 30 grams, on account of the presence of inert ash in the charcoal. Flour will reduce from 9 to 12 grams of lead per gram of flour, and it is therefore about twice as effective as argol, using equal weights of each.

Progress in the Coeur d'Alene.

STAFF CORRESPONDENCE.

Shipments of high-grade ore and concentrates from the Cœur d'Alene mining region of northern Idaho during 1906 amounted to 250,000 tons, of an average content of 50% lead and 25 oz. silver. The principal mines have been producing up to the limit of their milling capacities and they are not expected to increase their output in 1907. However, there will be an increase in the production of the newer companies which are developing their mines and building mills. The most marked developments on new property are in the vicinity of Burke and Mullan; and the prospect of a railroad being built to the Murray district this year is giving impetus to development in that part of the Cœur d'Alene. The larger mines of the region, namely, those of the Federal Mining & Smelting Co., Bunker Hill & Sullivan Mining & Concentrating Co., and the Hercules Mining Co. are understood to be under contract to ship their products to the plants of the American Smelting & Refining Co., but it may be noted that the United States Smelting, Refining & Mining Co. has entered this field as an ore buyer and is now taking the concentrate and high-grade ore of the Hecla at Burke, the Gold Hunter at Mullan, and those of some smaller properties.

The discovery of a copper producing zone some three miles east of Mullan, as testified by the development and production of the Snowstorm mine, has had the effect of attracting men and money from other copper mining regions, notably Butte; and the thorough exploration of that belt, both east and west from the Snowstorm, will certainly take place this year. It strikes in the direction of Burke and the uncovering of both lead and copper ores, associated together, west of the Snowstorm has created an interest that increases as the work progresses.

The Snowstorm, of which W. D. Greenough, of Mullan, is manager, is opened through a series of adit-levels, No. 1, 2, and 3. No. 3 is 723 ft. vertically below No. 2. The carbonate, or leaching ore, comes from levels No. 1 and 2, and carries 2.65% copper and 4.5 oz. silver. The ore in No. 3 level is a heavy sulphide. The vein stands nearly vertical and is said to range in width from 20 to 75 ft. The leaching plant, which is considered a success, will be handling 200 tons per day by February 15. The company ships about 250 tons per day of crude ore that is a mixture of carbonate and sulphide, running 4% copper and 6 oz. silver. It runs 90% silica and is received at the various smelters for use as converter lining. The company has expended $300,000 in equipment and improvement, and the manager now recommends to the stockholders that a concentrator and smelter be erected. No. 4 level, starting 3,000 ft. down the gulch from the portal of No. 3, has been driven 900 ft. and must be driven 2,500 ft. farther to cut the vein 600 ft. vertically below No. 3. Work is progressing on this. Mr. Greenough states that the mine is in condition to produce 2,000 tons of ore per day.

Wardner, Idaho. In the Coeur d'Alene.

The Gold Hunter M. & S. Co. is driving what is called No. 6 cross-cut to intersect the vein 700 ft. below the old workings. It is expected that work will be finished by September 1. This company employs 100 men, and mills its entire output of 200 tons per day. James Gearon, of Mullan, is manager.

The Hecla mine, at Burke, of which James F. McCarthy, of Wallace, is manager, has the only electrically operated hoist in the district. It is a converted steam-hoist, having flat cable, positive clutch, 300-h.p. motor, and operates to a depth of 1,000 ft. They also operate electric pumps at the 600 and 900 levels. The ore is hoisted to a landing 58 ft. above the collar of the shaft, then dumped upon a three-inch grizzly, the oversize going to a sorting belt from which the high-grade and waste are taken, the balance going to the mill-bin; the undersize goes to a one-inch grizzly that divides it for the coarse and fine sorting belts. By this method of sorting about 15 tons per day of high-grade are taken out for shipment and 25 tons per day of waste are eliminated.

The mill ore, sized and freed from waste, amounts to 300 tons per day. P. C. Schools, master mechanic, who likewise has charge of all electrical equipment, states that the application of electric power to hoisting has proved successful and satisfactory. The mine workings, including prospecting work, extend 3,000 ft. east from the shaft. The Hecla mill, at Gem, embodies equipment for the usual method of grinding, sizing, and concentrating by jigs, tables, and vanners. The principal change of late has been the installation of Callow screens and Callow settlers. The screens supplant the old system of hydraulic sizing.

The Hercules mill, a mile above Burke, has two bins, one for high-grade and the other for mill ore, transported over a surface tramway. The first class runs about 60% lead and 50 oz. silver; and the mill ore carries 6.5% lead and 7 oz. silver. A crusher, 9 by 15 in., reduces the ore to proper size for trommels and rolls. The ore feeds from a storage-bin to a double-screen trommel, the first two sections of which are 18 mm., whose undersize passes to an elevator; the undersize from the third section goes to a 36-mm. jig, the oversize to 16 by 36-in. Humphrey rolls. The middlings from 'bull' jigs pass to Humphrey rolls and its product by elevator to a three-section trommel; the first two sections are 12 mm., the third being 20 mm. The product of the 20-mm. size passes to two jigs, the oversize from this trommel to another 'bull' jig. What passes through the 12-mm. screen goes to the 36-in. twin trommel of 3 and 5 mm. The 3-mm. product goes to hydraulic classifiers and the 5-mm. product to jigs. On the jig floor are 12 sets of Hartz jigs. Callow screens are being put in to make a sized product for the tables, of which there are 18 Wilfleys. The middling from the jigs is re-ground in centrifugal high-speed rolls and a Huntington mill, the product of the latter passing to the tables. Frank Franz, mill foreman, states that the jigs make a 60% lead product. H. L. Day, of Wallace, is general manager of the Hercules.

The Frisco Mining Co., Ltd., of which Frederick Burbidge is manager, has partially re-equipped its mill near Gem, and at the time of the writer's visit was ready to resume operations. The mill was formerly operated as a lead concentrator, but it will now make a zinc concentrate as well. The ore from its mine carries 15% zinc, 8% lead, and 6 oz. silver. Recent additions to the mill's equipment comprise 6 Callow screens, 7 circular settling vats, 10 Wilfley tables, and one Dings' magnetic separator. The iron associated with the zinc is magnetic and this makes it possible to magnetically extract the greater part of it before passing the remainder to ordinary wet concentration. It is expected that from 60 to 70% of the zinc in the ore will be saved in a concentrate running about 45% zinc. The Frisco mine is 1,400 ft. deep, and is being sunk 200 ft. deeper. Electric pumps will be installed within the next 30 days. The company has been shipping some high-grade ore.

The Federal Mining & Smelting Co., of which W. Clayton Miller is general manager, has its general offices at Wallace and operates the Tiger mine at Burke; the Standard and Mammoth mines at Mace; the Morning mine at Mullan, and the Last Chance mine at Wardner. These mines produced 18% of the lead product of the United States in 1906. The 2,000-ft. shaft of the Tiger mine is being sunk 200 ft. deeper; the orebodies of the Mace mines are said to be much longer in the lower workings than they were on the upper levels. At the Morning mine No. 6 cross-cut, starting at the mill-level, has been advanced 2¼ miles to the main working shaft. The company is installing electric haulage and before this appears in print all ore from the mine will be conveyed to the mill and shipping bins through this No. 6 adit. This arrangement will cause a discontinuance of the use of the surface railroad, which has so long been operated in hauling ore and supplies between the mill and the upper levels. The change will bring about greater economy in getting the ore from mine to mill. The company's Tiger mill handles about 6,000 tons per month, its two mills at Wallace handle 28,000 tons per month, the Morning mill 27,000 tons, and the Last Chance mill between 13,000 and 14,000 tons, making an aggregate of 64,500 tons per month. The new slime plant at the Morning mill re-grinds and re-treats the fine jig tailing, using Huntington mills and the Callow system of sizing and settling, the products passing to Wilfley tables and vanners. In this way about 200 tons of slime per day is re-treated, making about 11 tons of fine concentrate per day that formerly passed into the river. This slime concentrate runs about 40 to 43% lead.

The Bunker Hill & Sullivan Mining & Concentrating

The Coeur d'Alene, Idaho.

Co., whose mines are at Wardner and mill at Kellogg, mined 919,039 tons of milling ore and 20,000 tons of shipping ore in 1906. Its product in that period amounted to 79,560,209 lb. of lead, 1,598,788 oz. silver, of a total value of $4,802,052. The dividends paid for the same period amounted to $7.80 per share, or $2,340,000. Stanly A. Easton, general manager of the company, states that the year's production was kept down somewhat by fires in some of the stopes last spring. Within the year large sums were spent in mine development and surface improvement, the latter including a new auxiliary concentrator to work over the one million tons of accumulated tailing stored near the main mill, and for re-treating part of the tailing product of the latter. The new plant, which is about ready for operating, has a capacity of 1,000 tons per 24 hours. It is equipped with four 6-ft. Huntington mills of the Anaconda type, Callow screens and vats for pulp classification and thickening, 16 Frue vanners, and 24 Wilfley tables. The accumulated tailing will first be treated in jigs without previous grinding, the jig product being ground in

Huntingtons before final treatment. General Electric Co. induction motors are installed to drive the machinery, the power being transmitted from the generators at Spokane falls. The most important mine development of the year was the sinking of an incline winze 400 ft. below the level of the Kellogg adit; and the opening of levels at 200 and 400 stations on this winze and the finding of ore on both levels.

The Surprise Mining Co., controlled by M. J. Sinclair and W. J. McLean, of Kellogg, has a property lying just back of Kellogg peak, on Pine creek. It adjoins the Highland Chief and is about two miles from the pay ground of the Bunker Hill & Sullivan. Its vein cuts through quartzite and slate and has been opened by crosscuts, disclosing a lead-zinc sulphide. The intention is to erect a concentrating mill early this spring.

The Success mill, on Nine Mile, near Wallace, is operating on a complex ore of zinc, lead, and iron, carried in a quartzite gangue. It is essentially a zinc-lead ore and the mill makes one concentrate running about 46% zinc, 1½% lead; also a concentrate having 50% lead and 28 oz. silver. The mill can handle 200 tons of ore per day and has a crusher, two sets of rolls, ten Willfley tables, three Callow screens, three Callow vats, and Hartz jigs. They have shipped as high as 40 tons of concentrate per day. H. F. Samuels, of Wallace, is in control of the property.

The Pittsburg Lead Co., operating the Black Cloud mine, on Nine Mile creek, has been doing important development work during the last year under general direction Stanly A. Easton, and it is understood their mill near Wallace will soon start up.

As a dynamo, by reversal of current, becomes a motor, so a steam-engine may become a compressor—the action may be noticed in a locomotive running light downhill; as originally made, compressors were ordinary steam-engines with air cylinders attached. At first sight it might appear that an engine working with 90 lb. of steam is subject to the same strain as a compressor delivering at that pressure; but the massive build of a well-designed compressor points to a different conclusion. In the engine the piston is receding from a decreasing pressure, in the compressor advancing against an increasing resistance; in the engine the load resists going forward, in the compressor it actively pushes backward; and in the latter the maximum steam and air pressures occur at opposite ends of the stroke, one being highest when the other is lowest, the balance being transmitted through the bed-plate and connections.

It has often been asserted that dredging of river-flats ruins the land for all time. That such is not the case in Southland the following extract from a recent issue of the *Standard* will show: "The trees planted on the tailings of the dredging claims on Mr. Sheddan's property at Waikaka Valley are growing lustily and are making a good show at present. The larch-trees in particular are looking well. Their appearance certainly assists to explode the belief that dredge-tailings are absolutely irreclaimable. Although retarded by the uneven surface, good rough grass is springing up among the tailings. There is little doubt that dredged land could be brought back to a good deal of its original pastoral productiveness at very little expense, represented by harrowing and some clod-breaking. Natural grasses are growing wonderfully on a lot of dredge-tailings in the district, and there is no reason to believe that English grasses would not thrive as well with a little expense in leveling the surface. For tilling purposes, of course, the land could not be sufficiently redeemed, but the argument is often urged by some of our politicians who are not too well informed on the subject that the dredging of land irreclaimably ruins it. Such is not the case. A good deal of the land in this district, notably in Wainumu and Charlton, and parts of Waikaka, is so swampy and broken that it is almost useless for pastoral purposes."—*The New Zealand Mines Record.*

Town of Burke. Tiger Mine to the Left, Hecla to the Right.

Shaft-Building by Raising.

Written for the MINING AND SCIENTIFIC PRESS
By W. H. STORMS.

To the enquiry of your correspondent at Weheville, Wash., relative to a method of shaft-building by means of raising, I venture to submit what I know to be a practicable scheme for accomplishing such work in a safe and expeditious manner. As I understand it, the raise is to have two compartments, but the enquirer neglects to state whether the raise is to be vertical or inclined.

Assuming that it is to be driven vertically upward, presumably at the side or end of an adit 500 ft. long, proceed as follows: At the place selected for beginning the raise, cut out a station large enough to accommodate the loading-chutes, car-tracks, and timbers, if the latter are neeessary. If only a single traek of 18-in. gauge is to be used, the station need not be more than 10 ft. long, 7 ft. wide, and 9 ft. high. If cars are to be loaded in trains and two tracks are required, it will be needed to cut the station 10 ft. wide. Should a track of wider gauge than

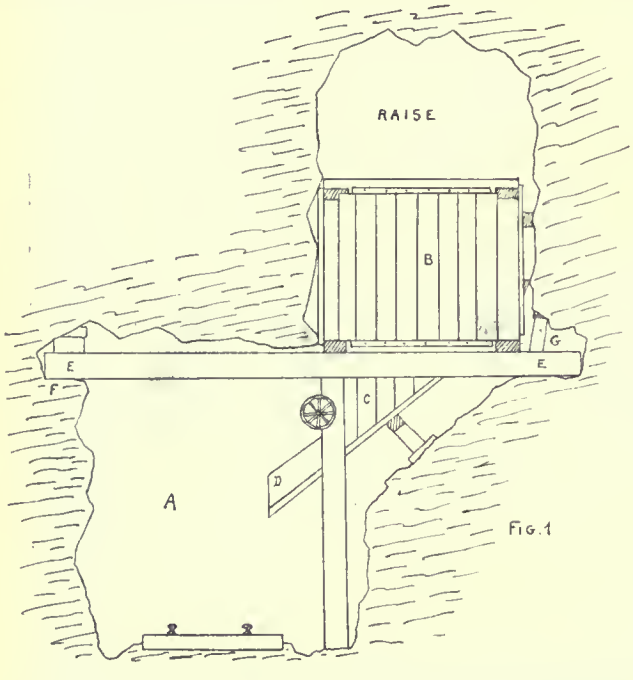


FIG. 1

18 in. be contemplated, the station must be correspondingly wider, but it need not be longer nor higher than the dimensions previously given.

The station forms a part of the adit, but the raise—to be later converted into a shaft—must be started above, and at one side of the station. The accompanying sketch (Fig. 1) shows the arrangement of shaft and chute-timbers, and the relative position of shaft and station.

When the raise has been started, as shown, hitches should be cut each end of the shaft at *F* and *G*, to hold long heavy timbers, *E*, the dimensions of which must be determined by the character of the ground. If in hard and firm rock, timbers 8 by 10 in. (8 in. side up) will be large enough; if the ground be soft and heavy, the timbers must be larger, and the hitches cut deeper, and they may even require heavy posts beneath, as these bearers may have to support the shaft for a distance of 50 or 60 ft. above the top of the station. The bearers also form a solid back for the ore-bin and chute-timbers. Beneath the raise the rock may be blasted out, sloping back from the station, as shown in Fig. 1.

Up to the time the raise has advanced upward 12 ft. all the rock broken should be shoveled into cars from boards placed on the floor for this purpose. The bearers should then be put in place in the hitches *F* and *G*, and firmly wedged. Care must be taken that the bearers are perfectly level, and that they conform exactly to the inside vertical lines of the proposed shaft. The size of the raise is optional, but should be suited to the amount of work proposed to be done through it. A shaft having two compartments, each 4 by 5 ft., is a convenient size and large enough for ordinary purposes. This will make a shaft 5 ft. by 8 ft. 8 in. clear, including an 8-in. divider.

When the raise has been cut 12 ft. above the back of the station, that is, the level of the bearers, and these latter are in place, the first set of shaft-timbers must be placed in position. This set comprises two wall-plates, two end-plates, a divider, separating the two compartments, and four posts. If 8 by 8 in. timbers be used, the wall-plates will be 10 ft. long, the end-plates 6 by 4 in. long, and the divider 5 ft. 2½ in. long, including tenons.

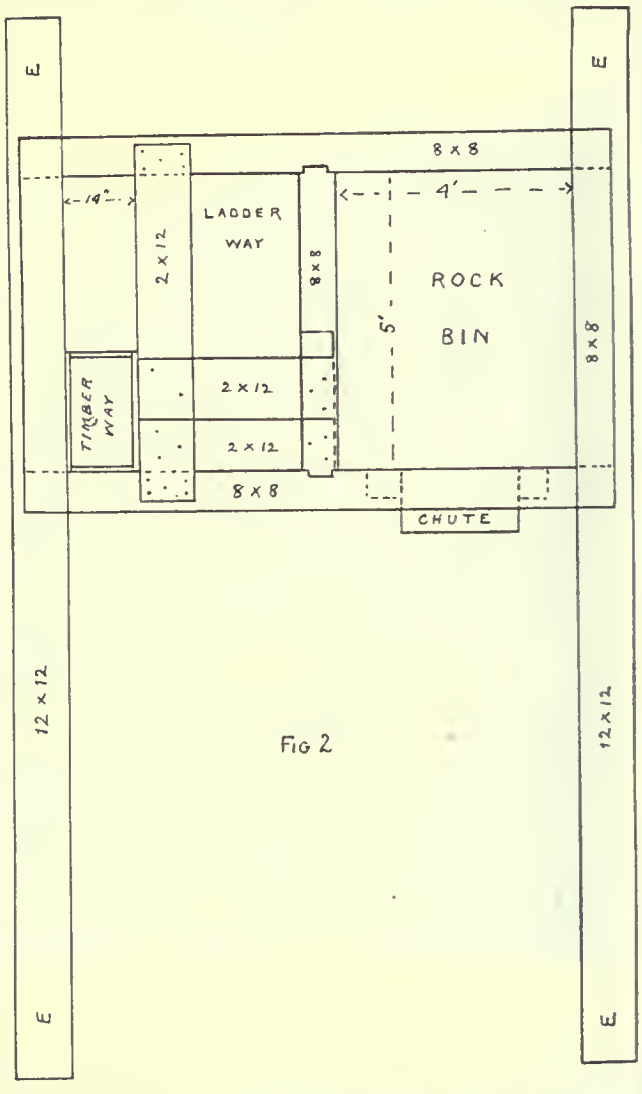

FIG 2

Fig. 2 shows a plan of the shaft at the level of the bearers.

The style of framing timbers is left to the miner. Either the overlap or the dovetail corner is good. The latter is particularly applicable to inclines, but may also be safely used in vertical shafts and requires a little less timber than the overlap. Fig. 3 shows the manner of framing plates for the overlap, and Fig. 4 illustrates the dovetail.

When the lowest set of plates has been fixed in position, resting on the bearers, and securely wedged, set up the four posts, being careful that they rest squarely in the daps cut for them on the ends of the low plates. The posts may be temporarily secured in position by means of 1 by 4 in. strips nailed to plates and posts, forming braces. On these four posts now place the timbers constituting the second set of plates; block and wedge them firmly, as with the lower set. Remove the 1 by 4 braces, put lagging in position, all around the shaft if necessary, and secure it by placing blocks of wood, rocks, or wedges

between the lagging and the rock-walls of the shaft. Much time may often be saved by nailing a strip 2 by 2 in. horizontally on the outer side of each plate, both ends and sides, placing them about the centre of the plates, making the strips nearly as long as the timbers. On these the lagging may rest and be blocked to place with little trouble and no loss of time. When the lagging is all in place the first shaft set is complete.

Build the rock-bin beneath one compartment, as shown in Fig. 2, the other compartment to be used as a man-

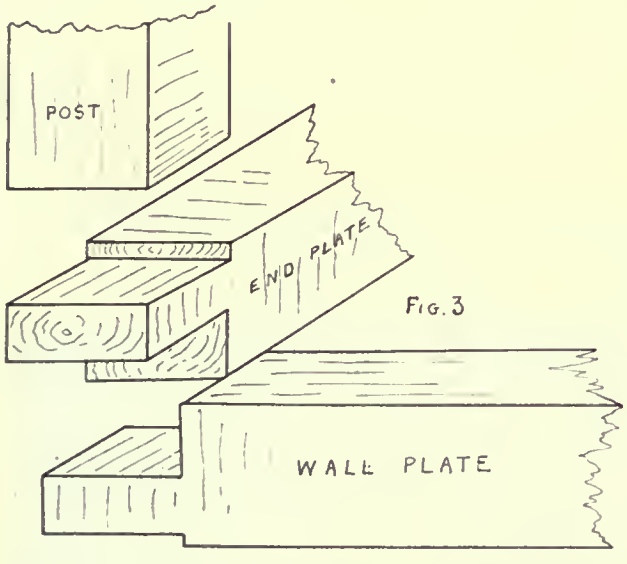

FIG. 3

way, and for the accommodation of pipes, wires, and ladders; also as a passage-way for timbers, and to raise and lower machine-drills and other tools.

Place a ladder on the floor of the station leading up to the first set. It may be placed in any desired position

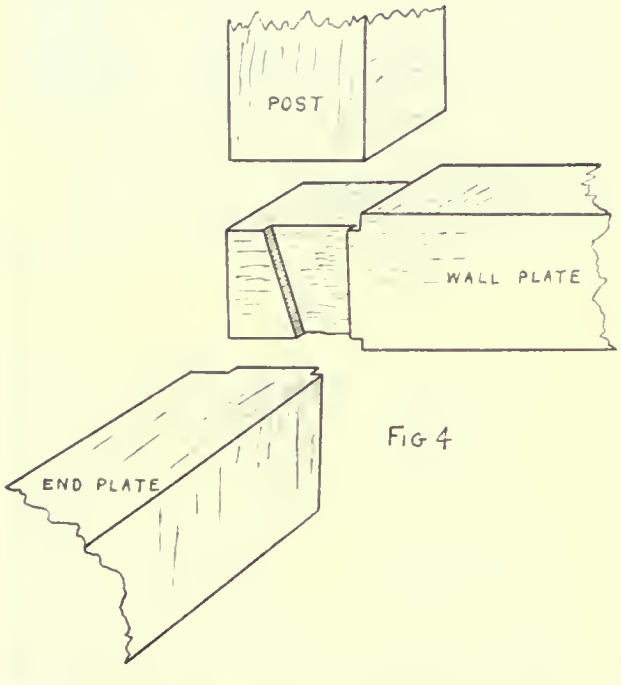

FIG 4

clear of the track. Two movable ladders must now be provided, to be used as the work progresses, one about 6 ft. 6 in. long, the other about 12 ft. Ladders made of 2 by 4 in. scantling with 1 by 4 in. steps are commonly used, the steps being set flush. The space between the sides should be at least 14 in. and the distance from the top of one step to the top of the next should not exceed 12 in. A number of ladders should be made for permanent use, 16 ft. 6 in. long, that is, to reach the height of three sets, when the ladder rests at an inclination of 70°. In vertical shafts, strong and properly made ladders are an absolute necessity. Never place ladders vertically when they can be set at an inclination.

It may be as well to explain here how ladders should be placed in a vertical shaft. Put them in the man-way compartment and on the side adjoining the dividers. This leaves the other end of the same compartment open for pipes, and for the passing of timbers, tools, and supplies, while the raise is in process of being driven. At every third set above the first spike a 2 by 12 in. plank across the shaft parallel with the dividers and 22 in. from it; on the divider spike a piece of 2 by 4 in. plank 24 in. long. Across these spike, side by side, and parallel with the wall-plates, two pieces of 2 by 12, 40 in. long, and at one side of the shaft. This leaves a man-hole at

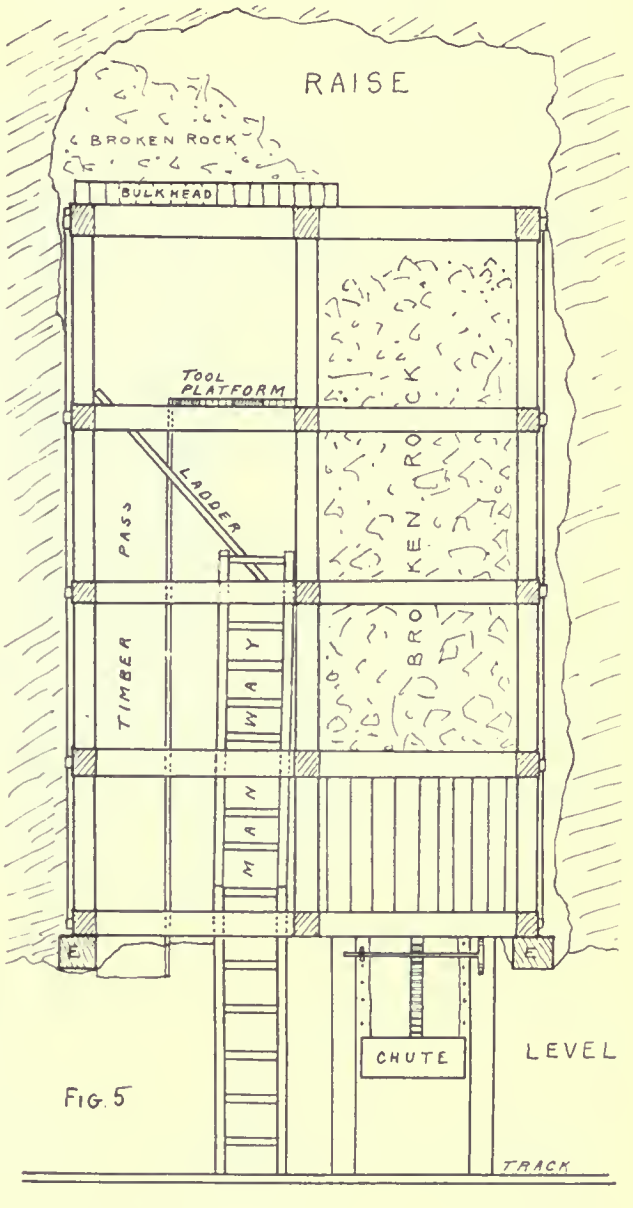

FIG. 5

every third set 22 in. wide and 36 in. long. The ladders should be placed on the platforms and 8 in. from the wall-plates, and should extend at least 12 in. above the set at the upper end. It is also a good idea to provide a substantial hand-hold 12 in. above the top of each ladder, as an aid to men who may be carrying tools or other things up or down the raise. An iron staple 8 in. wide, driven into the lagging at the side of the shaft, or a piece of 2 by 4 in. scantling spiked to cleats at a convenient place may be used.

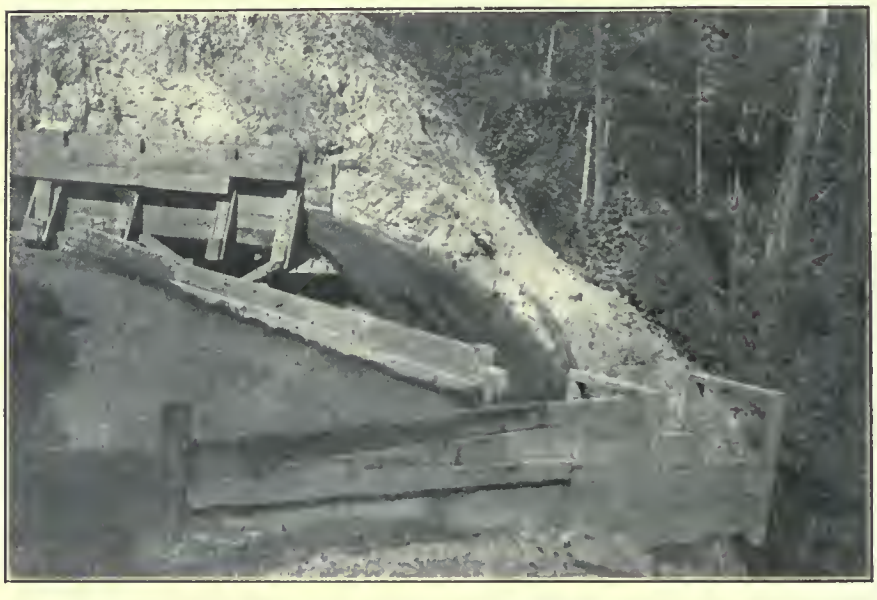
The ladders should be set one above another, and always inclined in the same direction, so that a man, having reached the top of the ladder, steps to one side upon the plank platform and back to the foot of the next ladder, continuing the ascent. This arrangement leaves

an open space at one end of the shaft 14 in. by 5 ft. To expedite the hoisting of timbers, machines, and other things up to the working place, a portion of this open space should be boxed-in on four sides. This chute may be constructed of 2-in. plank, and, if it be made tight, it will greatly aid ventilation—a most important matter, when raising, under any conditions.

Having described the method of placing ladders, platforms, etc., we may now resume mining operations. Assuming that we have cut our raise to a height of 12 ft. above the bearers, and that we have placed a complete set in position, put a short ladder reaching from the first platform to the top of the last set, and over the man-way compartment construct a bulkhead of 8 by 8 in. timbers, leaving the rock-compartment uncovered. Spike lagging vertically on the four sides of the rock-compartment (inside). Drill a full round of holes in the back of the raise. These holes should be loaded as lightly as possible, just sufficient to break down the rock. When ready to fire, remove two or three of the timbers of the bulkhead, in order to go down through the man-way. The machine-drill and other tools may be placed on a platform built on the set beneath; the holes over the manway side are then 'spit'; the timbers of the bulkhead are replaced, the men retiring to a safe distance in the adit. When the smoke has cleared, after blasting, the miners return to the raise and, removing some of the lagging leading to the rock-compartment, pass through and climb upon the bulkhead. After barring down all the loose rock possible, they clear the bulkhead of rock, care being taken that no rocks too large to pass the chute-door below are allowed to go down into the bin. The holes over the rock-compartment are then loaded and fired, the men going below through a hole in the bulkhead and pulling the timbers back into place as before. By shooting the back out in two rounds, in this manner, the chute can be protected to a great extent, and little, if any, damage results to the timbers. Again the miners return, passing through a hole in the lagging which is made secure before blasting again. The loose rock is once more barred down, and all rock on the bulkhead is shoveled into the rock-compartment. If the holes have broken well there will probably be more rock than can be accommodated by the ore-bin and the single set of the shaft above it. In this case the men could not return to their work before drawing off several cars of rock at the chute, and it may be necessary to do this after the first round is fired. Never draw more than necessary to get through the lagging from the man-way into the rock-compartment. Throughout the entire operation of cutting this raise, the rock-compartment must never be drawn off lower than four feet from the top of the uppermost set, and leaving as much more rock as possible.

When sufficient headway has been made, another set of timbers is placed in position and the bulkhead is moved up one set, and also the temporary platform upon which are placed the tools when ready to blast. When four sets are in position the first permanent ladder may be put in place, and the construction of the box-chute commenced. After each full round, the rock broken down usually fills the rock-compartment and covers the bulkhead. If the fuses of the holes over the bulkhead are cut so as to cause those holes to go first, the broken rock will afford some protection to the shaft-timbers, but after each round some rock must be drawn from the chute in order to permit the men to return to their work at the top of the raise. The work proceeds in the manner described, the timber sets being placed as fast as room can be made for them. Timbers can only be lined up by the use of a spirit level. In shaft-sinking four plumb-lines are generally used, but that is not practicable in this case. By exercise of care the sets may be kept well in line by using a long leveling instrument such as a carpenter or machinist employs.

The question of ventilation is all-important, but may usually be satisfactorily solved by carrying a pipe close up to the bulkhead, or the timber-chute in the man-way may be used for this purpose. If a machine-drill is employed, the exhaust from it will aid ventilation materially. If the air-tight box be built in the man-way compartment as previously suggested, good ventilation may be facilitated by turning a jet of compressed air into the bottom of the box. This will induce a strong upward current in the box and a corresponding downward current in the open compartment.



Under-Currents at the End of Sluice-Boxes.

THE discoveries of science are made by steps which are perfectly simple to those trained to follow them. No discovery is made by chance in our day. None come to contradict existing laws or to discredit existing knowledge. The whole of no phenomenon is known to man. The whole truth never can be. Ultimate truth was never in any man's possession. The unknown surrounds on all sides all knowledge in man's possession. The beginning, the end, and the ramifications are beyond his reach. He was not present when the foundations of the universe were laid. He may not be present when they are destroyed. But scientific knowledge, though limited, is practical and positive so far as it goes. It rests on experiment and observation alone. Every step in observation, experiment, or induction has been tested by thousands of bright minds. He is already a master in science who can suggest even one new experiment. There is nothing occult or uncanny in scientific methods. The 'magic wand' which creates new species of horses or cattle lies in the hand of any stock breeder. The magic key of the electrician by which the foam of the cataract becomes the light of the city may be held by any municipal council.

Loss of Gold in Placer Mining.

Written for the MINING AND SCIENTIFIC PRESS
By DENNIS H. STOVALL.

In the placer fields of northern California and southern Oregon every effort is made to make mining methods efficient. Iron and wood has been replaced by steel, ditches have been widened and deepened, reservoirs enlarged and set on higher ground, and the head of water employed has been raised from 200 or 250 ft. (which was the heaviest possible with an old-time equipment) to 450 and even 520 ft. A giant working under such tremendous pressure as this, maintains a cutting power at a distance of 400 ft. from the foot of the gravel bank. In the Royal Group hydraulic mine in southern Oregon, two giants operating under a head of 510 ft. hurl their streams 500 ft., biting off the gravel in slabs of a thousand tons. But the manager of the Royal Group, like other placer managers on the Pacific Coast, is discovering the important truth that the entire attention of the placer miner must not be confined to moving of the gravel, to the neglect of gold saving.

Monitor at Work on the Royal Group Hydraulic Mine.

The sluices and riffles are not catching the gold, and in a great majority of the mines they are saving none of the platinum. Since the bedrock race affords the best possible riffle for catching and saving the gold, the placer miner will find it to his advantage to make this race as long as possible, or at least of ample length, before discharging the water and flowing gravel into the sluices. The sluices must be provided with more efficient riffles.

Sluice-boxes, in their general arrangement, are but little different today from what they were fifty years ago; except that now a sort of standard is adopted. A sluice-box, in placer mining parlance, means a 12-ft. section of the entire sluice. These sections are interchangeable, each box being an independent piece and made to fit, end to end, with its neighbor. This not only facilitates cleaning up, but the sluice-ways can be more readily and easily shifted about, especially where the dumping ground is not deep, and a new dump must be made at intervals during the season.

So, after all, the sluice-box itself is not a gold-saver, it is merely the receptacle that holds the riffle, and through which the auriferous stuff flows. And the problem therefore is to make the present riffle more efficient, or replace it with a better one. Experienced placer miners state that the 'non-boiling' riffle is the best for saving gold. The old idea that a riffle must offer 'resistance' to the gold, is not sound. Repeated practical tests and actual experience has taught a few, and will teach others in the course of time, that the riffle that saves the greatest percentage is the riffle that offers the least resistance, but which allows the gold and the platinum sand ample chance to settle.

The common block riffle, which is generally used, possibly because it is the most convenient to make, is a 'boiling' riffle of the worst kind. It consists of five or six-inch blocks sawed, squared, and set in pairs on the sluice floor. The blocks are cut and set with the lower side higher than the upper, to increase agitation and 'resistance,' and a crevice two inches wide and the depth of the block is the receptacle in which the gold and black sand lodge. About one-half the gold and all the platinum, kept constantly on the surface of the current by the agitation of the water, fails to settle and flows over the dump. Only the heavier nuggets and pieces drop into the crevices between the blocks.

Pole riffles are made of four-inch poles laid side by side the whole length of the sluice floor, which can be lifted out at clean-up, just as is done with block riffles. Pole riffles have been found to be more efficient than blocks, simply because they are laid lengthwise and do not 'boil' the water.

A durable and efficient riffle that is used by some of the bigger mines of Oregon and California, is made of railroad rails, placed bottom-side up, tilted just a little, and set an inch or more apart on the sluice floor. The sluice current flows smoothly over this riffle, giving the

gold ample opportunity to settle into the crevices between the rails. While such riffles will practically wear for all time, they are a difficult thing to secure, and are heavy to handle.

A riffle that has the efficiency of the railroad iron, but is cheaper and more easily handled, is made by setting 2 by 4 in. scantlings edgewise on the sluice floor, and two inches apart. Slightly bevel the top edge and bolt strap iron on it, the straps being a half inch wider than the scantling. This riffle does not produce agitation, and the gold and platinum sand settle in the crevices between the scantling. Riffles of this sort, cleated together, and made of a width and length to fit each sluice section, can be readily set into the boxes, and as readily lifted and rinsed when the time comes to clean up.

The fine 'flour' gold, as the miners call it, is elusive stuff, and most difficult to save. At the Royal Group mines, undercurrents are used to catch and save this 'flour gold.' Near the end of the sluiceway, and as close to the dump as possible, about one-fourth or one-third of the water is drawn down through an open grizzly on the sluice floor. This water is nearest the bottom and in it are nearly all the fine particles of 'flour' gold. It is spread out over a set of broad riffle-tables where the fine gold and sand settle. These riffle-tables are covered with burlap or some such material, to arrest the gold; they are easily lifted and rinsed in vats of water, where the values settle and are later saved by scooping up and carefully panning over still water.

The more careful placer miners are learning that much fine gold and platinum are lost by the time-honored custom of cleaning up and panning in the running water of the sluice. When clean-up time arrives, the riffles are lifted and carefully rinsed. The sand, containing gold and platinum, is scooped up and panned over vats of still water, instead of allowing a steady stream to flow through the sluice for this purpose. The first panning is for the gold, letting the black sand and platinum particles, which are lighter, boil over and settle in the vat. This sand is taken up later and panned separately. While this method is more tedious than the old way, it results in a far greater saving.

TRANSVAAL OUTPUT.—We take from the *Transvaal Leader* the following data: During the year 1906 the Transvaal produced gold to the value of £24,516,704, as against £20,860,141 in 1905. The number of stamps dropping returned at the end of November was 8,350, of which 8,005 were on the Rand, comparing with 5,835 stamps at the end of 1905. The dividends declared for the year 1906 by Rand gold companies amount to £5,565,970, against £4,754,348 in 1905. Of the total distribution the mines employing Chinese only for unskilled labor paid in dividends £1,099,450; and allowing a proportion due to the labor of the Chinese on the Geldenhuis Deep, New Heriot, Nourse Mines, and Rose Deep, which are worked partly by Chinese and partly by Kaffirs, Chinese labor may be said to have contributed £1,367,210 of the dividends declared in 1906. The nominal capital of the companies that paid dividends is £23,131,284, on which the return shown is about 24%. The profit distributed is estimated at 23.67% of the production, as against 23.9% in 1905; or, put another way, the profit distributed amounted to 4s. 9d. out of every 20s. of gold produced, against 4s. 9¼d. last year. The total profit of the dividend-paying companies is estimated at £8,150,000 for the year, out of which the amount declared in dividends comes to 70%, the remainder being accounted for by profits tax (equal to 5d. out of every sovereign produced, or 7½ to 8% of the profit), special reserves, debenture interest, renewals, and so forth.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

The possession of the surface of a mining claim is the possession of a vein or lode having its apex within the surface lines of the claim, although extending downward, such vein may pass within the vertical side lines of the claim, and will support an action of trespass for the removal of ore from such vein beneath the surface of an adjoining claim.

Montana Mining Co. *v.* St. Louis Mining, etc., Co., 147 Fed. 897.

A lease of a mine for railroads provided that the lessee should work and develop the premises in a mine-like fashion, and in a manner conformable to good and economical mining, and so as to take out the greatest amount of ore possible and to do a certain amount of work each month; it was further provided that a failure to do so would be a violation of the covenants of the lease. Under such a lease it was not optional whether the lessor would comply with the requirements as to working and developing the mine, and that his failure to comply merely entitled the lessor to forfeit the lease; but on the contrary it imposed on the lessee the obligation to work the mine in the manner specified or to respond in damages for failure so to do. The amount of recovery under such a lease would depend on the amount of ore that could have been mined if any reasonable diligence had been exercised.

Macon *v.* Trowbridge, (Colo.) 87 Pac. 1,147.

The location of a mining claim has the effect to segregate such land from the public domain, and until some act or laches of the locator occur by which the title reverts to the Government, there can be no re-location.

Slothower *v.* Hunter, (Wyo.) 88 Pac. 36.

A statute provided that a certificate of a mining location should contain a description of the claim by such designation of natural and fixed objects as should identify the claim. Under this statute a certificate was held *prima facie* sufficient which described the location in a designated mining district and county and further described the claim as lying west of other designated claims. The failure to give distances and directions did not affect its validity. It was further held that the failure to recover the certificate within sixty days did not render it invalid; the effect of such failure being that it might affect intervening rights.

Slothower *v.* Hunter, (Wyo.) 88 Pac. 36.

A lessee of a mining claim who has contracted to do an amount of work thereon which would be a sufficient compliance with the legal requirements in respect of development, and also to notify the lessor of any intention to surrrender or abandon the lease, cannot on failing to perform his obligations secretly re-locate the claim, and so secure and hold the title for himself. A patent obtained under such circumstances was decreed to be held in trust for the lessor.

Stewart *v.* Westlake, 148 Fed. 349.

The statute provides that within 90 days after the posting of a notice of a mine claim, the locator must sink a shaft on the claim to a depth of 10 ft. from the lowest part of the rim of the shaft at the surface, or deeper, if necessary to show a well defined crevice or deposit; or in lieu of this he shall make a cut, cross-cut, or tunnel which cuts a lode at a depth of 10 ft. below the surface or an open-cut of at least 10 ft. in length along the lode from the point where the lode may be in any manner discovered. Neither of these requirements were satisfied by a declaration which merely stated that the locator within the 90 days dug "a tunnel at the point of discovery of the following dimensions: About 12 ft. long, 6 by 4½ ft. cut 3 ft. deep, 6 ft. wide, wherein is disclosed a well defined crevice and valuable deposit of ore." The declaratory statement was defective in not showing that vein or lode was not cut at the depth of 10 ft. below the surface.

Dolan *v.* Passmore, (Mont.) 85 Pac. 1,034.

Mining in Nevada.

By CHARLES G. YALE.

*Nevada is at present attracting more attention from the mining and speculative public than any other mining State in the West. This interest is largely based on prospective values, but there is no doubt that some of the mines already productive are making such a showing as to give confidence both in themselves and in others still in course of development in the same camps. Moreover, while the present excitement has been brought about by the developments in the newer camps of southern Nevada, it is also true that many of the older camps known for thirty or forty years have again become the seats of great activity.

After the working out of the great and famous bonanzas of the Consolidated California & Virginia mine on the Comstock and the failure for many years to find new orebodies of value in any of the mines in that extensive lode, the mining public turned its attention elsewhere. As a result Nevada became neglected. It became difficult to obtain capital for investment in any of the mining districts, no matter what prospective showing was made. The annual bullion production of the State continued to decrease until it became a small amount as compared with the output in the palmy days of the Comstock lode.

The revival of interest in the mining industry of the State may be said to date from the discovery of ore at Tonopah about five years ago. As developments progressed at Tonopah it became apparent that the camp bid fair to become as permanent as old Virginia City itself. It has taken strenuous development work and large investment to bring Tonopah to its present position, but during the progress of this work the swarms of prospectors and miners attracted there spread over the adjoining region and discovered several other camps, some of them already overshadowing Tonopah itself in point of productiveness.

As one after another of these new districts were discovered and rich bodies of ore were found the mining world began to realize the great importance of the region under development. Both miners and investing capitalists saw opportunities for enriching themselves. An abundance of money was forthcoming for any mining venture. Miners obtained grubstakes with ease, secured valuable leases, were enabled to sell their best ore for cash as soon as it was brought to the surface, or could sell their claims outright for good prices if they so desired. It was possible also to obtain the money at once for equipment and development of any claim making any sort of showing. Under these conditions, not always prevailing in new districts, it is small wonder that remarkable and rapid development has taken place throughout southern Nevada. Moreover, the claims themselves merited the work done upon them as has been shown by the financial results, the most potent factor in the success which has followed the opening of the districts referred to.

The building of new railroads across Nevada had already been projected when these mines were discovered, but the mining developments have caused much more rapid construction of these roads and also the building from main lines of others designed to furnish transportation for the more important camps. Only the richest of the ore could bear transportation where long wagon hauls were necessary to reach the railroad lines, but it is a matter of astonishment that such large quantities of ore were shipped under the circumstances. The nearest smelting works—hundreds of miles away—became overcrowded with ore from the new mines, and thousands of tons of second-grade ores have been piled on the dumps waiting for cheaper transportation or local reduction works.

It seems odd now, in view of subsequent development, that the first of the new camps, Tonopah, was held back a year or more by the lack of faith in the mines on the part of the companies which had bought the more prominent claims. Instead of proceeding on their own account, they adopted the leasing system, thus avoiding further investment and letting the lessees themselves prove the value of the claims. This they did, however, in short order, not only making fortunes for themselves, but making great mines out of mere prospects, to the benefit of the more timid companies.

It may be confessed that to the leasing system is largely due the magnificent developments which have been made in many of the mines of the new camps. Some few of the companies have, of course, done their own work, but the lessees have really performed most of it. Some of these leases have resulted in the output of millions of dollars. Most of them expire early in 1907.

There is a wide area of the southern desert section of Nevada over which prospecting operations are now being conducted, and this mineral belt has been found to continue over into Inyo county within the California boundary.

This review of the conditions existing in Nevada, accompanied by the statistics for 1905, refers only to that year, but it may not be out of place to write briefly of some features relating to a subsequent date, as they have been largely influential in bringing about the present widespread interest in the mining affairs of the State. The most important development in any single mine has been that which has occurred in the Mohawk mine, at Goldfield, where the richness and quantity of the ores obtained by the lessees during 1906 have arrested the attention of the mining world. From published reports concerning the leases in this mine (not verified by the United States Geological Survey) it appears that from April 18 to November 20, 1906, the gross value of the ores shipped by the various lessees in this mine amounted to $4,075,919, and the net values to $3,135,426. They also had ore stored and in transit amounting in value to $950,000 additional. It was estimated also that over $1,000,000 would be recovered during the remainder of the life of the leases, which expire in January, 1907. On November 20, 1906, the Mohawk merger took place, by which the Goldfield Consolidated Mines Company acquired the Mohawk, the Red Top, the Jumbo, and the Laguna properties, and they will be hereafter worked as one. The company has been organized with 5,000,000 shares of capital stock, par value $10 per share. Before the consolidation these separate properties had produced a total gross sum of $6,054,610. The Mohawk did not produce until 1906; the Jumbo began producing in July, 1904. The Red Top ore has been reduced in a small local mill operated under lease.

The average freight and treatment rate on ores shipped to smelters for 1906 has been $23.50 per ton. The cost of treatment of oxidized ores in the Combination Mines Co. mill for the same period has been $5.82 per ton, with about 91% extraction. This cost will be further reduced by a mill treating a large tonnage, and this mill has now been constructed. The mines are well developed considering the short time which has been occupied in the work. Under the leasing system, although the ore was exceptionally rich and the life of the lease short, there has doubtless been much robbing of the mine, which will not be the case when systematic development work is conducted by the company itself.

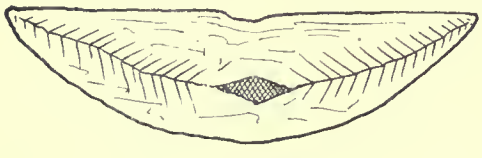
Silver-Lead Smelting Practice.

By T. S. AUSTIN.

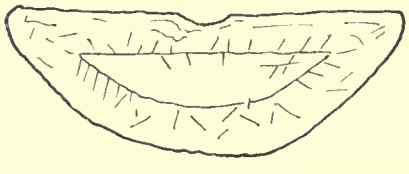
Edited for the MINING AND SCIENTIFIC PRESS by L. S. AUSTIN.*

SLAG COMPOSITION AND CHARACTERISTICS.—[In a letter written in June, 1883, he goes into the subject of the physical appearances indicating a good half-slag. It will be noted that formerly the metallurgist, before altering his charge for its improvement, went by these indications, while today he depends largely upon the results obtained from chemical determinations. The remarks are as follows:]

About half-slags (of the type $SiO_2 = 30$, $FeO = 40$, and $CaO = 20$ per cent).—The appearance in the pot is generally that of more or less concentric rings and radiated lines across the rings from the centre. A good pot generally quarters, that is, it divides on the surface into quarters when nearly full. It must show a slight drip, or even a decided one, if over acid. If it has an excess of lime and is yet acid enough, it will not show the feather. The comb or spout should be 6 to 10 in. long. The hand-sample (taken in a hand-ladle), and the big pots will show large crystals; the more iron the larger the crystals. Lime gives a granular structure in the pots and hand-sample, though I prefer to have lime slightly



Acid-limy slag.



Acid slag

in excess, provided the slag is acid. A good half-slag has, in the hand-sample, the crystalline structure clear to the edge, as also in the big pots, thus:

Should you have a structure where the lines do not run up to the edge and where the corner has a sort of an unfinished look with a reddish tinge, it is apt to be acid thus: If the cavities do not show well-defined crystals, but are smooth and hard-looking, it shows almost invariably too much iron for the silica. The big pots, when smooth on top, show an excess of lime.

Finally, the best slag is the one that is the cleanest, and which keeps the furnace open. There is no royal road to slags any more than to learning; they must be studied out. The first thing is to get a slag acid enough, and then you can work out the relation of iron to lime.

FURNACE OPERATIONS AT THE RIO GRANDE SMELTING WORKS, 1892.—[In regard to the general technical operation of these works, he advised according to methods applicable today, treating the subject in detail as follows:]

Slags: I have pretty generally adopted the three-quarter as the working slag. It is more economical of iron than the half-slag, and, I think, keeps the furnace in good shape just as well. For Salt Lake conditions you may figure it at 33% SiO_2, 33% FeO and MnO, and 23% CaO. This will, for those constituents, add up to 89%. BaO and MgO, when you have them, are substituted for CaO inversely in the ratio of their atomic weight.

For my particular conditions, however, I run a modified three-quarter slag. I figure SiO_2 and FeO as being equal, add the RO bases (ZnO and Al_2O_3 chiefly), and make up to 100% with CaO. The three constituents SiO_2, Fe, and CaO then commonly add up to 83%. If I take SiO_2 and FeO at 66%, there remains 17% for the CaO. This slag has the main physical characters of the three-quarter type. Now, Raht would call this a half-slag, the CaO being half the FeO, but I think my theory, that it belongs in the three-quarter family, is the correct one, because of the SiO_2 and FeO ratios, and because I deduced the slag composition from the three-quarter basis. Raht, at Pueblo, runs a slag of high silica, say 33 to 35%, and then figures his lime to one-half or a little more of the FeO present. Of course, he thus neglects the other bases, namely, MgO, BaO, Al_2O_3, and ZnO, which his ores likewise contain. He gets to about the same place as I do, because his neglected bases are about the same as mine. Now, it might be possible for you to figure an acid half-slag and reach the same point that he does. If you can get more silica on the charge, it will pay you better, provided you do not have to increase iron and lime. I would be very careful about it, but still would try to work up to it. Of course high-silica slags contain more silver than the more basic ones, other things being equal. I mean, that with high silica, you must use more fuel and run slower, but you get so much nicer crucible work.

While the slag type is to be worked out for each locality, I may say that certain general rules obtain everywhere, thus: High-silica slags give high silver unless run slowly, and, even then, are not sure to give good results. They are so viscid when very silicious, and mechanically carry so much matte, that I deprecate their use under any conditions. Medium-silica slags are less objectionable, and give good furnace work. Low silica gives better general work.

In the half-slag, I define these thus: Low silica, 30%; medium silica, 32 to 33%; and high, 33% upward.

Silicious or infusible slags of any kind are apt to induce a hot top, and, for this reason, I object to the one-to-one type, which is very infusible when in its acid form. It also runs slowly. As regards the value carried off in the slag, observe that when it approaches an irony-acid character in any type, the silver will run higher than normal. Of course, this kind of a slag runs nicer, as far as furnace working is concerned, but you will have to count on larger losses. Copper acts strongly to remove the silver from slags, and, whenever you have matte in large quantity on the charge (and good in copper grade), you may look for materially lower silver assays of the slag. To offset this you have those crucible troubles that copper always engenders.

Zinc: I find 3 to 5% in my slags (at Socorro, N. M.) and the lime on those slags is always low when the zinc occurs in form of ZnO. I figure half the zinc on the charge and make that the amount of the replacing lime. Here are some analyses:

	FeO + MnO	SiO_2	CaO	ZnO	
I	32.1	32.0	21.5	4.8	Ladle sample
II	35.0	32.3	20.1	5.0	" "
III	31.0	33.2	22.2	3.0	Crystals
IV	33.9	33.2	21.0	3.0	Ladle sample
V	36.2	34.0	17.8	5.5	" "
VI	34.8	31.7	19.8	4.2	" "

It will be seen that in these the lime and zinc oxide about make up the right amount of the 'lime base,' that is, 24 to 26%. Sometimes the FeO runs over 34% and the silica is often lower than 33%, but you will observe

*These observations of T. S. Austin, recently deceased, general superintendent of the Southern Department of the American Smelting & Refining Co., are compiled from letters written by him to his brother, from 1883 to 1906, covering most of the period of his wide experience in silver-lead smelting, and to some extent that in base-bullion refining. They lack some of his recent experiences, but show that much of his knowledge had been brought into finished form some time before his death. The notes refer largely to his work at Socorro, New Mexico, Monterey and Chihuahua, Mexico, and to El Paso, Texas, together with other technical observations made during that time. Professor L. S. Austin's remarks are in brackets.

that they are pretty close to the figured amounts, respectively (FeO = 34 and SiO_2 = 33%). I find I am compelled to get a lower lime than 24%, in order to get good work. [He does not, however, bother about variations in alumina when it is in moderate quantity.] After all, general appearance is the guide in furnace running, and, if you can get some types of crystals and surface characteristics, you will be all right. [He notes that lately he has found a peculiar thing, namely, that the slag crystals were much higher in silver than the main bulk of the slag—something contrary to all his former experience.]

[Regarding the use of a basic slag, where zinc (especially in oxidized form) is present, he remarks:] The difficulty with such low silica is that you crowd silicious ore off the charge and smelt the more expensive flux. The little saving in lead (by running the more basic slag) does not begin to compensate for the commercial losses of less silver ore, more flux, and more coke relatively to the ore-tonnage. The labor, per ton of ore, is also increased, and the furnace does not keep in as good a condition in the crucible. Imagine the effect of reducing silica to 30% and increasing FeO and CaO by 6%. It means adding nearly 20% inert matter to your charge and paying for smelting it, that is, increasing the cost of smelting 20%. When at the Grant works (where a low silicious slag is used), I noticed them cutting out an ugly crucible-crust, due to over-reduction (0.2% Pb in the slag). This low percentage does not indicate a good slag, but rather the use of too much fuel. I do not understand that their furnaces have a large tonnage, and the cleanness of their slags may be due to slow running induced by excessive fuel. I doubt if they have grasped the theory of blast-furnace reactions as Raht has, simply because they do not handle their furnaces on the same lines. His results are obtained by running on the "ragged edge" of reduction, and he gets large tonnage, furnaces in splendid condition, long campaigns, and good metallurgical work by being "onto the fuel racket." I work on the same lines, and no one can make me believe that it is good metallurgy to use so much fuel as to practically clean the slag from lead.

Alumina: In regard to alumina, I would try treating it as a base. I have never had any experience with it myself, but, though there is a theory extant that it sometimes acts as an acid, I do not know of any proof positive, except one trial by Schneider in a little furnace, that it does take that part.* James, at the Germania (1888), has had experience with it, and tells me that it acts as a base as far as he knows. I also know that it has been run here at the Graphic works, taking the place of lime. I would not lower either silica or iron unless the slag showed very acid, and then of course the silica. I would figure the lime in ratio of its equivalence to alumina (CaO, 56; Al_2O_3, 103), or one pound of lime as equal to two pounds of alumina. Therefore, if you calculate for 23% CaO, and it comes down 18%, there is 5% displaced by 10% Al_2O_3. Of course, the silica and the iron will be lowered at the same time, and you will have a basic slag. You need not be afraid of any moderately acid slag, and an excessively acid one even, will not do much harm, as it can be quickly corrected by eye. See to it that your trouble does not come from some mechanical cause, such as insufficient blast or some other irregularity. Subjoined are the analyses of two copper-furnace slags:

I.		II.	
SiO_2	26.64%	SiO_2	34.31%
FeO	42.60	FeO	32.27
ZnO	0.62	MnO	6.24
CaO	9.51	CaO	10.13
Al_2O_3	15.40	MgO	2.30
		Al_2O_3	11.80
	94.77		97.08

*Trans., A. I. M. E., Vol. XI, p. 56.

We have here two extremes, but the amount of iron with the less silica is the larger. Of course, that approximating No. II would be the one for our use, making the FeO and MnO less, and the CaO more.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The samples from Diamond Springs, Cal., marked H. S., are impure Clay containing much Iron and Manganese. There is nothing of value in the material.

The specimens from Concord, Cal., marked S. A. S., are nodules of Clay and Shale. A thin layer of Calcite has been deposited as a coating on some of the pieces.

C. A. P., of National City, Cal., sends black sand composed mostly of Magnetite grains, but also having Ilmenite, Chromite, Quartz, Garnet, Zircon, and Chrysolite intermixed.

The rocks from Hornitos, Cal., marked J. B. F., are: No. 1, white Quartz containing fine granular Galena and a small amount of Sphalerite; No. 2, Quartz with Chalcopyrite, Galena, and Sphalerite.

The specimen sent by C. S. McM., of Iron Springs, Idaho, are all metamorphosed rocks. No. 1 has schistose structure and contains green chlorite stains; No. 2, Quartz; No. 3 is Feldspar and Quartz; No. 4, a chloritic rock containing many small cubes of Pyrite.

The ores from E. A. C., Goldfield, show bronze-colored Bornite and streaks of a dark gray metallic mineral, which gives reactions for copper, iron, silver, antimony, and sulphur. No tellurium reaction was obtained. The mineral is a Sulph-antimonite, probably an iron-rich Tetrahedrite. The green coating also gives no reaction for tellurium, but shows chlorine, iron, copper, and silver. It may be a chloride, but the amount of material was insufficient to determine definitely its nature.

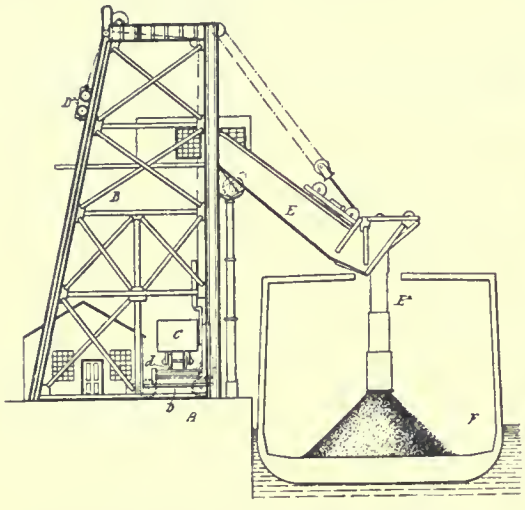
IN THE first half of the last century England was possessed with a Spanish mining fever, which led to the launching of all sorts of enterprises to exploit the mineral wealth of old Spain, of Mexico, and of South America. The fever for Mexican mining did not abate until leeches had been applied to the extent of about fifty million dollars. Failures were made with mines which today are doing well; and the difference in result is not all in the greater experience or added knowledge of the present day, it is due to the avoidance of an extravagance which in the former era took the special form of bringing a staff and even workmen from England, people who knew neither the country nor the ways of it, and delighted in importing the most ponderous kind of machinery and the greatest variety of supplies at ruinous rates of transport.

THE decided rise in the price of antimony is probably due to the increased demand for it in the machine industries, to the partial replacement of tin (which is now scarce and expensive), in babbitt and bearing metal, to the poverty of the deposits as they are opened up to greater depth, and to the relatively increased price of all metals as compared to the constant price of gold. There is a growing demand for it as a pigment, because it has the advantage over white lead of being innocuous, and over zinc paint, of being permanent and sun-proof.

MINING AND METALLURGICAL PATENTS.

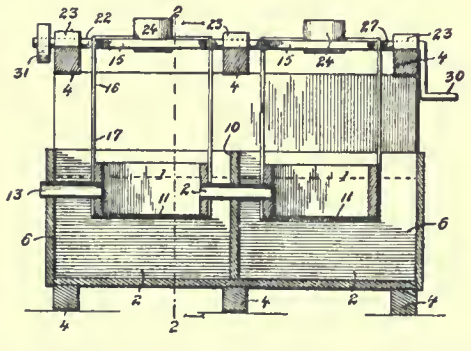
Specially Reported for the MINING AND SCIENTIFIC PRESS.

SCREEN FOR CAR-DUMPING APPARATUS.—No. 843,334; Charles A. Fry, New York, N. Y., assignor, by mesne assignments, to Dodge Coal Storage Company, Saugatuck, Conn., a Corporation of Connecticut.



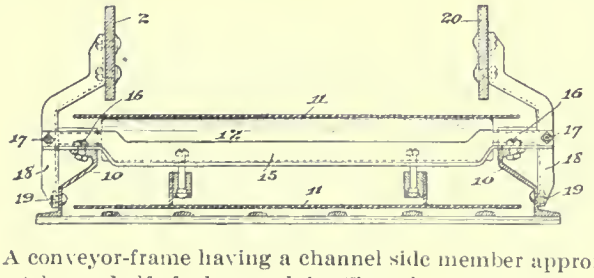
The combination in a car-dumping apparatus, of a structure, a platform for carrying the car, means for dumping the platform and the car, a chute at one side of the structure into which the material is discharged from the car, a screen at the inner end of the chute, a trough under the screen, a conveyor in the trough, a telescopic tube connecting with the trough, a screenings-hopper, and a conveyor leading from the outlet end of the telescopic tube to the screenings-hopper.

ORE-SEPARATOR.—No. 843,086; Lucian B. Hunter, Greeley, Colorado.



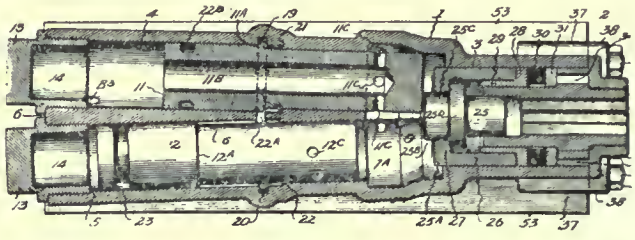
In an ore-separator, the combination, of a plurality of tanks, a jig-box in each tank, flexible conductors connecting the jig-boxes, levers having one end slotted and the other end forked to form arms, pivot-shafts passing through the arms, hangers pivoted to the ends of the arms, the jig-boxes secured between the lower ends of the hangers and depending into the tanks, counterbalance-weights having intersecting slots to engage and rest on the forked portions of the levers, and means for oscillating the levers.

CONVEYOR.—No. 842,900; William H. Morenus, Lake View, Iowa, and Frank R. Jones, Harvey, Ill., assignors to Austin Manufacturing Company, Chicago, Ill., a Corporation of Illinois.



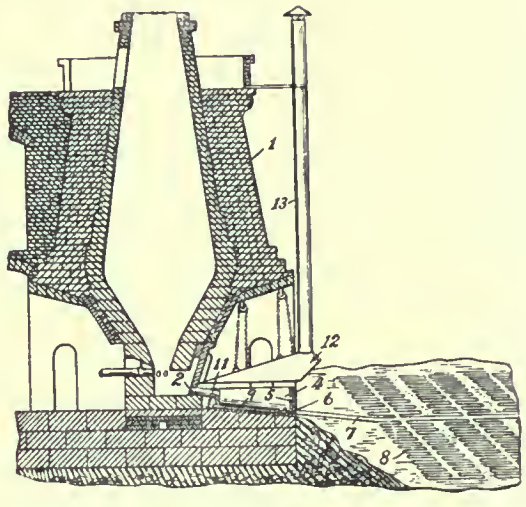
A conveyor-frame having a channel side member approximately one-half of whose web is offset, the exterior surfaces of the channel's flanges being parallel. The combination of a frame, the side members of which are channels, the upper parts of which are inwardly offset and the flanges of which project outwardly with their exterior surfaces parallel, suitably-mounted rollers, and an endless conveyor-belt, said belt being of sufficient width whereby its longitudinal edges lie above and below the offset webs of said side channels.

MULTIPLE-HAMMER-PISTON ROCK-DRILLING ENGINE.—No. 843,159; John G. Leyner, Denver, Colorado



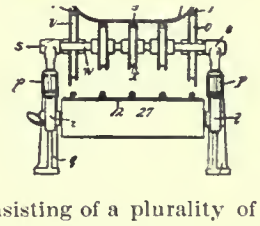
A rock-drilling engine, comprising a casing containing two cylinders arranged at an acute angle to each other, a hammer-piston in each of said cylinders, means to secure a drill in the front end of said casing and means to reciprocate said hammer-pistons to deliver alternate blows upon said drill.

TREATMENT OF IRON AND STEEL.—No. 843,569; Harry Luckenbach, San Francisco, Cal., assignor of part interest to William H. Kelly, San Francisco, Cal., George L. Robinson, Frederick E. Fishel, and Joseph J. Robinson, New York, N. Y., and Frederick F. Nolte.



The process of purifying iron which consists in generating steam, superheating the steam, passing the superheated steam into the bottom of a vessel adapted to contain molten iron until the issuing steam is entirely free from moisture, then tapping the molten iron into said vessel from the blast-furnace, and continuing the injection of the superheated steam into the molten iron while at rest in said vessel.

CONVEYOR.—No. 843,018; James A. Jamieson, Montreal, Quebec, Canada.



A conveyor consisting of a plurality of traveling flexible lengths and a flexible apron resting loosely thereon and the flexible lengths supporting the apron in the form of a trough, a conveyor consisting of a plurality of series of sheaves, the sheaves of each series being arranged in tandem relation to the sheaves of the other series, a flexible length supported by each tandem series of sheaves and an endless apron looped over and resting loosely upon and supported in the form of a trough by such flexible lengths.

Henry C. Sergeant.

Henry Clark Sergeant, of the Ingersoll-Sergeant Drill Co.—now an integral part of the Ingersoll-Rand Co.—died at his home, Westfield, N. J., January 30, at the age of seventy-two years.

Mr. Sergeant won a world-wide repute as a facile, prolific, and highly successful inventor, especially in the design of rock-drills, air-compressors, and mining and excavating machinery in general, his active life having been coincident with the period of development of the modern apparatus now so universally employed and so industrially efficient, he having been a leading and active agent not only in the invention and improvement of machinery but also in the devising of the details and the means of precise and economical manufacture. He was born at Rochester, N. Y., but his earlier years were spent in Ohio. He was of untiring activity, both physical and mental, from the beginning. He had only a common-school education and was working in the machine-shop at a very early age. His irrepressible inventive faculty made work for itself from the first. He quickly began to see the undeveloped possibilities of systematic manufacture by the aid of special machinery. His first practical application of his theories was to the making of spokes, hubs, and felloes of wagon wheels. He designed special machines for this work and at the age of eighteen he accepted a contract for manufacturing wheel parts in quantity. In this he was so successful that in two years he was taken into partnership by a firm manufacturing wagon wheels.

The routine of the factory, however, could not hold him, and after severing this first business connection the next six years of his life were spent in various pursuits, chiefly commercial, in which he met with varying success. He was a ready speaker, though not known as such in later years, and found favor as a lecturer. He had figured for a time also as a champion skater. He still found time and opportunity for the invention and development of labor-saving machinery.

Mr. Sergeant's first patent, issued when he was nineteen, was for a boiler feed. Succeeding patents suggest the range of his inventive faculty. In December, 1858, he patented a steam-engine governor. This was a governor for marine engines to prevent their racing to destruction when the wheels were out of the water. This was adopted by the Government and applied to the warships of the period. After that he secured patents for gas-regulators, for steam-pumps, four for steam-boilers, five for brick-machines, a fluting-machine, six for water-meters, and all these were invented before he had struck what must now be considered his life work.

Three of the brick-machine patents were issued in 1867 when he was a resident of Columbus, Ohio, but soon after that he started a machine-shop of his own in New York, developing many crude ideas into practical working successes. In the early '70s hither came Simon Ingersoll with the drawings for the first Ingersoll rock-drill, a then untried device. The possibilities of the rock-drill attracted Sergeant. None can say now how much he contributed to the development and success of the original Ingersoll drill, but at least one patent was issued to Ingersoll and Sergeant as joint inventors. The Ingersoll Drill Co. was formed and placed the drill on the market.

Although the drill was at first operated by steam, its advantages when driven by compressed air and the absolute necessity of using air for mine and tunnel work, turned Sergeant's attention to the improving of the design and details of the air-compressors, which the Ingersoll Company began to market in connection with the drills and for other incidental uses. He was soon working with all his energies in both directions and constantly bringing both the drill and the compressor to higher efficacy. As the business grew, the partnership of Sergeant & Cullingworth was formed, with shops at 22nd St. and Second Avenue, New York.

Again, turning from the task of manufacturing, Mr. Sergeant's interest was sold to the Ingersoll Drill Co. and he went to Colorado to put into practical operation some of his mining methods. He operated a silver mine for a time, but fortunately we may now say, it was not a success. Meanwhile he had developed another complete rock-drill with an entirely novel valve motion. Two patents on this drill are dated 1884. He brought this new drill East in 1886 and formed the Sergeant Drill Co., which began building the drill at Bridgeport, Conn. Two years later the new company joined hands with the Ingersoll interests and the Ingersoll-Sergeant Drill Co. was formed, with Mr. Sergeant as its first president. The new company's shops were at 9th Ave. and 27th St., these shops having been occupied for a short time previously by the firm of Sergeant & Cullingworth, which then went out of existence, Mr. Sergeant's interest in this firm having terminated before he went to Colorado.

Mr. Sergeant remained at the head of the company but a short time, he then disposing of the bulk of his interest, and going on a visit to London and Paris. He returned to the rock-drill business, this time as a director in the Ingersoll-Sergeant Company, with the purpose of devoting all his time to invention. He labored constantly in developing and improving the company's products and in spreading their application into new and wider fields, his most notable inventions being the Sergeant 'auxiliary' and 'arc' valve, tappet' rock-drills, the 'release rotation' for rock-drills, and the 'piston inlet' valve for air-compressors, all of which are in general and successful use today. He was also the originator of many new ideas in stone channeling and coal under-cutting.

In the days of the Sergeant & Cullingworth Co., in response to the solicitations of the management of the Third Avenue Elevated Railroad Co., of which he was then a director, for a device which would protect them from the constant losses accruing from the repeated use of uncancelled tickets, he designed the ticket-cancelling box now so familiar to the public, that so mutilates the ticket as to make it impossible to defraud the company by using it again.

Mr. Sergeant's inventive faculty and his suggestive ideas were devoted to the interests of the Ingersoll-Sergeant Co. for all the remaining years of his active life, and the business grew and prospered continually. The works at Easton, Pa., were occupied in 1873, the great shops at Phillipsburg becoming a necessity a decade later, the consolidation of the two foremost, but competing companies, in their line in the world into the Ingersoll-Rand Co. being also a natural sequence. He spent much of his time in Easton until two years ago, when failing health compelled him to give up his former activities.

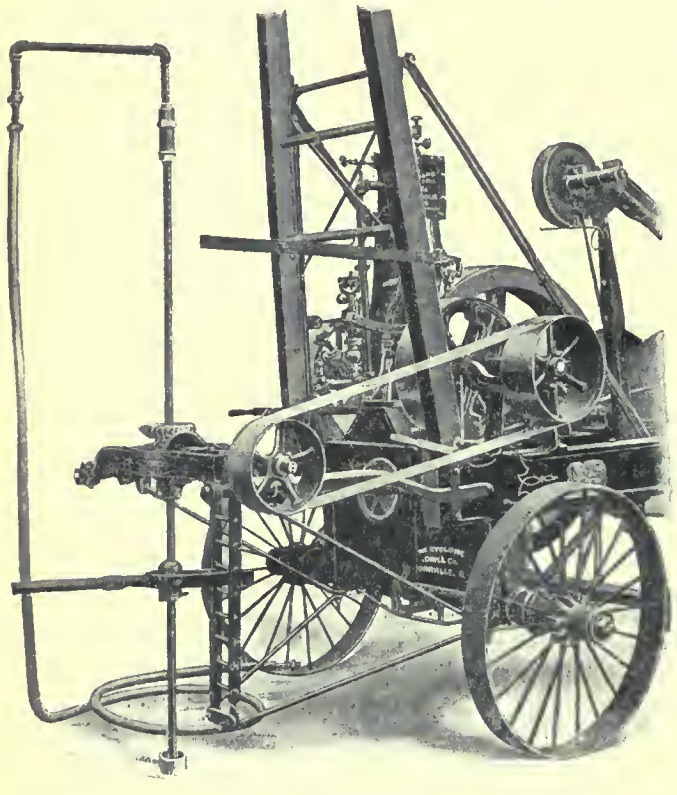
After the consolidation of the Ingersoll Sergeant and the Rand companies he still retained his interest, although his health would not permit his active participation.

In his early days Mr. Sergeant was never content to tarry long under fixed conditions or in the same place, and up to 1893 he had made his home in 26 different cities and towns. In that year he settled at Westfield, N. J., and at once took a deep interest in the growth of what was then but a small settlement. He built and owned at the time of his death the present home of the Westfield Club, the leading social organization of that neighborhood. He was a great sufferer from the rheumatism in his later years, but the immediate cause of his death was paralysis. He is survived by three daughters, a son, and a brother. Mr. Sergeant was a man of all embracing interests and of most extensive experience, a genial companion in the hours of leisure, as he was an indefatigable worker when anything was to be done. He was absolutely without ostentation and there was no suggestion about him of his talents or his achievements. He had, however, an unbounded confidence in his abilities, as all must have who accomplish much.

Mr. Sergeant is to be considered to have been a fortunate inventor, in that his inventions were so completely successful in the accomplishment of the purposes for which they were designed, and have attained such a leading position in the large operations that accompany the advance of modern civilized life, although he realized from them no great fortune, as fortunes go now, and at best attained little more than a modest competence.

The Cyclone Drill.

The Cyclone Drill Co., of Orrville, Ohio, which has been a leading manufacturer of prospecting drills for a number of years, has completed an addition to its plant that will more than double their capacity. The wood and paint shop building is 62 by 120 ft.; machine-shop addition, 40 by 64 ft.; and the forge-shop addition, 40 by 60 ft. New equipment is being added in each department. The company is now prepared to turn out an average of one cyclone drilling machine per day and it finds these increased facilities necessary owing to the growing demand for these drills. An important improvement has just been perfected for all these machines, which consists of a core attachment, enabling the prospector to obtain cores of just such part of the strata as he desires. By this means the character of the prospected area can be determined at any depth, at the minimum of cost; and a core can be extracted on any point desired without taking a core of the entire depth. Prospectors are advised to look into this new feature, and complete description will be sent on request. Prompt shipments will be made.



The Cyclone Drill.

Commercial Paragraphs.

THE ALLIS-CHALMERS CO., of Milwaukee, issue Bulletin No. 1,403, describing the Hancock jig, and stating the saving that has followed the use of this machine.

THE COMPRESSED AIR MACHINERY CO., of San Francisco, has been appointed Pacific Coast sales agent for the Olds Gas Power Co., of Lansing, Mich., and has a full stock of their gasoline engines.

THE CHICAGO PNEUMATIC TOOL CO., of Chicago, has prepared a handsome pamphlet, called the Electrical Tool Catalogue, No. 21, describing the electric drills, grinders, drilling stands, magnetic old-man hoists, etc., manufactured by them.

THE SULLIVAN MACHINERY CO., of Chicago, has established a branch office and warehouse at 12 South 20th St. Rock-drills and their parts, and other machinery will be carried in stock, for immediate shipment. Inquiries and specifications for mining and quarrying machinery are invited, and will receive prompt attention.

The new branch office of the LINK-BELT COMPANY, of Philadelphia, Chicago, and Indianapolis, is at No. 440 New York Block, Seattle, Wash.; E. G. Brabrook is in charge. Increasing business from the Far East, Washington, Oregon, and surrounding territory, in the conveying-machinery manufactured by the company, made personal representation on the Pacific Coast desirable.

THE RISDON IRON & LOCOMOTIVE WORKS report having closed a second contract for a 10-stamp mill for the Kodiak Gold Mining Co. This mill goes into Uyak, Alaska. It is a complete mill with concentrating plant and also has a large compressor plant. The entire outfit is to be run by water-power, there being a separate wheel for the mill, one for the concentrators and a large wheel on the compressor-shaft; the compressor is of a duplex type.

Books Received.

SYNOPSIS OF MINERAL CHARACTERS, by Ralph W. Richards, Assistant in Mineralogy, Harvard University. 12mo., 99 pages. Published by John Wiley & Sons. Price, $1.25. This is designed to present in a systematic form the essential characters and the simplest determinative reactions of the common minerals.

ELECTRICAL ENGINEERING, by E. Rosenberg. This is an elementary text-book suitable for those employed in the engineering trade, for students and for others that need a knowledge of the underlying principles of the subject. It is a translation from the German, revised by Edward B. Raymond. 8vo., 347 pages. Well illustrated. Published by John Wiley & Sons, and for sale by the MINING AND SCIENTIFIC PRESS, for two dollars.

SELF-PROPELLED VEHICLES.—A practical treatise on all forms of automobiles, by James E. Homans. Published by Theo. Audel & Co., 63 Fifth Ave., New York. The author has emphasized the practical aspects of motor vehicles of all powers, confining his space to the discussion of matters fundamental in construction and management. Theoretical matters — important almost wholly to designers and builders—are introduced only where good explanations positively require them, and at no point is the reader's mind burdened with padded material on experimental and obsolete construction.

Publications Received.

BULLETIN of the Massachusetts Institute of Technology; Vol. 42, No. 2.

ANNUAL REPORT of the Mining Industry of Idaho. 1906. By Robert N. Bell, State Inspector of Mines.

ILLINOIS STATE GEOLOGICAL SURVEY issues Bulletin No. 1 and No. 2, the first giving a geological map of Illinois, by Stuart Weller, and the second is devoted to 'The Petroleum Industry of Southeastern Illinois,' by W. S. Blackley.

ANNUAL REPORT of the Smithsonian Institution. 1905. This volume of 575 pages includes several important papers, such as those on 'The Genesis of the Diamond,' by Gardner F. Williams; 'Gold in Science and Industry,' by G. T. Bielby; 'History of Photography,' by Robert Hunt, and a number of other scientific articles.

Trade Treatises.

COLORADO IRON WORKS CO., Denver, issues Bulletin No. 25, describing their highly successful A & E slime concentrator.

THE GOHEEN MANUFACTURING CO., of Canton, Ohio, send us a copy of Zevy's 'Engineer's Book of Estimates,' a valuable series of forms and tables.

ALLIS-CHALMERS CO. issue a reprint of their Bulletin No. 1,038 on the 'Alternating Current Generator.' It is mainly a picture book, as the illustrations constitute the main interest of it.

INGERSOLL-RAND CO., of New York, issues Catalogue H 36, describing the Ingersoll-Sergeant class H air and gas compressors. The pamphlet is well illustrated and gives some useful information on duplex construction in this class of machines.

Editorial.

WE REPRINT an interesting address delivered by Mr. F. W. McNair, president of the Michigan College of Mines, on deep mining in Michigan. As one of the leaders of the American Association for the Advancement of Science and as the head of the faculty in a school of mines that has won a reputation for practical teaching, he exemplifies the close relationship of science to industry.

BOSTON is likely to lose its distinction as the copper mining market; State Street is to become secondary to Wall Street, even in 'coppers.' Granby Consolidated has been listed on the New York Exchange, and Utah Consolidated is to follow. It is stated that the governors of the New York Stock Exchange are making concessions to mining companies to induce listing and to cause a growth of business in mining stocks. If this means that speculation in mining shares will be recognized to be as legitimate as any other form of stock gambling and if at the same time such dealings are to be placed under proper control, it will be well. At present the buying and selling of mining stocks is done mainly on that peripatetic market known as the Curb.

BERKELEY is becoming celebrated at this time by reason of the spirited effort being made to remove the seat of State government from Sacramento, and place it in the town usually identified with the University of California. It is probable that the Legislature will agree to submit the question of change, from Sacramento to Berkeley, to the people at the next general State election. Undoubtedly Berkeley is more convenient, being close to San Francisco and to other populous cities on the Bay; it is also a more pleasant and a more healthy place for the assembling of legislators. From the standpoint of site, no finer exists in the round world than on the lower slopes of the Contra Costa hills, facing the Golden Gate and affording a panorama in which the harbor and the estuary, the islands and the mountains, are canopied by the blue of a summer sky. But good scenery is wasted on a legislature, so there remains the fact that to the bulk of the population of the State, to politicians, to lobbyists, to reporters, and to those who have proper business at the capitol, the town in which we live is eminently accessible and desirable as a place of sojourn. There is left only the question of the effect on the University; at present, no selling of alcoholic stimulants is permitted within a mile of the campus; will this effort to safeguard youth be negatived by the introduction of the disreputable elements that hang about a legislative centre? Will contact with 'statesmen' undermine the ethics of the University student? Will he become too familiar with the actualities of graft? On the whole, we

think not. The capitol will be a couple of miles from the campus, and will exert no more influence on the life of the University than the neighboring city of San Francisco. Therefore, the town of Berkeley ought to sacrifice itself for the sake of the State and consent to becoming the seat of government.

The Position of the Railroads.

Signs multiply that the railroad companies are becoming aware of the growth of a public opinion unfriendly to them, for the financial papers of Boston and New York are publishing leading articles against the "unreasoning public sentiment" and the growth of "a lack of confidence on the part of investors" that it is feared may undermine the industrial stability of the country. The "anti-corporation propaganda" are imputed to hysteria and the community is urged to mind its own business and drop this senseless interference with the wheels of prosperity. On the page opposite we reprint portions of an article appearing in the current *Review of Reviews* that has the merit of voicing the general disgust with revelations of railroad inefficiency and corruption. It is a matter of importance to every one in the community and particularly to the miner, whose operations are usually conducted at such a distance from the manufacturing centres as to make him largely dependent on railroad transport. The disclosure of the part played by Pennsylvania Railroad officials in favoring coal companies in which they were stockholders, did undoubtedly astonish many people by whom this great railway system was considered a model of efficiency, but the practices exposed in this case are common among the smaller railroads in the West, the managers of which, either personally or in a corporate way, become interested in mines. In many cases preferential rates made to the owners of mines are based on mutual interests or personal factors, all of which seem harmless at first, but in the end are but insidious forms of corruption. Such dealings spring from the absence of a sense of responsibility to the community; there is a complete forgetfulness of the fact that the railroad has been granted a privilege that is to be used for the general good and not for private gain. Much in the same way the bigness of Mr. E. H. Harriman's manipulation of railroad stocks and his speculation with enormous sums of money has shocked some people, but to many others the magnitude of the transactions obscures the essential wrong. If a cashier of a country bank uses $5,000 to gamble on the race-track, the character of his performances is rightly appreciated, but if a railroad magnate plunges on Wall Street with about $50,000,000 of Union Pacific funds, he is dubbed a great financier. It is this tendency of railroad presidents to be speculators on a huge scale instead of attending to their duties as the chiefs of a big transportation business, that has shaken the faith of the community. There is too much attention to the ticker and too little to the road, too much reading of the tape and too little interest in departmental reports. And this applies, of course, not to the president only but to the whole run of officials to whom he sets a pernicious example; hence the mismanagement, the painful frequency of accidents, and the unprecedented freight congestion. A railroad is not a private undertaking, but a public institution. It may be that demagogues and journalists are exaggerating the existing evils and this exaggeration may create general lack of confidence, but that is bound to be the case whenever corruption is exposed. Life insurance is not disgraced because the Equitable got into a scandal, but the performances of Mr. Hyde and his friends opened the eyes of the policy-holders to the mismanagement of trust funds and prepared the way for a healthier tone in insurance matters. We hope the present campaign of inquiry will do a similar service for the railroads. They enjoy special privileges, they must use them wisely and for the benefit of the community, by whom they were granted; and this may seem a utopian sentiment to the people of California—a State debauched by the Southern Pacific for so long that its corrupting domination has become an accepted fact. We hope for the growth of a strong but sane sentiment on the subject, able to insist that a public franchise is not a mere synonym either for private or corporate betrayal of trust.

Larder Lake.

Any rich new district is apt to give rise to mining excitements of a spurious kind, especially in the surrounding region. Thus Goldfield and Tonopah have been the hatchery for a lot of small fry, that serve mainly to feed a gullible public. In the same way the fame of Cobalt has stimulated prospecting in northern Ontario and has been the cause of several booms. Among these is the Larder Lake excitement, which is attracting twenty prospectors per day, over the two available routes. We are in a position to warn real miners from going thither, for while there is plenty of quartz at Larder lake, it is very poor, so that while money may be made by buying and selling of claims, there is no present basis for a legitimate mining industry. There are no indications even of big bodies of quartz running four or five dollars per ton in gold. Nor are the conditions conducive to cheap mining. Being a flat country, shaft-sinking is necessary; water is plentiful and is likely to be troublesome; good timber is scarce, although there is plenty of slim poplars and spruce for fuel. The formation is a chloritic schist, with areas of quartzite. The quartz is of that milk-white kind that experienced men consider unfavorable; iron pyrite is abundant, but it is poor in gold. The region is unsurveyed, therefore much confusion and many lawsuits are inevitable and some claims will be annulled by reason of failure to make proper discovery. At present, most of the prospectors on the ground are woodsmen and farmers, with no experience of mining. In the Western States it would be foolish for a man to flourish an assay-certificate showing a dollar or less per ton and expect $5,000 for his claim, but that typifies the spirit prevailing in the Larder Lake district. Some purchases have been made even on this basis, but only with the idea of unloading on the public through the medium of a stock company. The local opinion is that one good find, which is yet to be made, will prevent a slump in the spring.

By the Way.

In the current issue of the *Review of Reviews* there is an excellent article on the railroad situation. In part, it is said:

The principal argument against such governmental ownership has been the superior practical efficiency of private direction and management. But unless conditions notoriously prevalent just now should soon be changed for the better, the public-ownership advocates will become confident and aggressive along a wholly new line of advance, where they have heretofore been on the defensive. They will point to the complete breaking down of efficiency in the actual business of transportation in this country, and will begin to claim that the Government could not possibly do things so badly.

Furthermore, they will point to the inability of the great railroad managers to obtain the money they need to make absolutely necessary improvements, whereas the Government of the United States could obtain almost unlimited capital at half the rate of interest the railroads would be obliged to pay. It does not follow that these new arguments will be conclusive. There is no evidence as yet to show that the people of the United States, justly exasperated with the railroad managers as they have become, are by any means prepared to throw the burden of railroad ownership and administration upon the United States Government. On the other hand, they will heartily support the Government in its present policy of investigating abuses. Government inquiry has disclosed the fact that, in spite of drastic laws, the railroads have been continuing the general practice of rebates and favoritism.

The responsible railroad managers have for several years past looked the country straight in the face and declared that they were scrupulously obeying the laws against discrimination. But when the Bureau of Corporations and the Interstate Commerce Commission proceed to make investigations, and the Department of Justice takes an active hand in the business, it turns out that by all sorts of ingenious methods, direct and indirect, the favored patrons of our railroads are aided by the railroad officials to break down their competitors in business. The bigger element of railroad men, instead of attending to the practical business for which the stockholders are supposed to be paying them their salaries, are to be found in Wall Street and in the large New York hotels, building up their private fortunes by day, and pursuing their pleasures by night. The smaller fry of railroad officials have been the holders of stocks in coal companies, grain elevator companies, and other enterprises along the line, and it would be absurd to deny that as the prevailing rule such companies and enterprises have been favored with a supply of freight cars and other facilities for doing business, when their competitors and the general public have been denied. When things like this have been alleged against railroad officials, they have turned their eyes to heaven with protestations against the injustice of such slanderous accusations. But a moderate amount of energetic effort on the part of the Government investigators brings these things to light.

The ordinary stockholder in the railroad is just as helpless as the unfavored shipper of freight. A great game of railroad strategy has been going on in Wall Street for years past, and one of its principal objects has been to freeze the small investor out, and to concentrate the actual ownership as well as the control of the railroads in a few hands. Thus the most conspicuous achievement of our boasted railroad system within the past few years has been the making of a group of multi-millionaires who have rendered little, if any, return to the stockholders or to the country for their vast acquisitions of wealth and power. They have juggled with securities, have played the stock market up and down, have played tricks with their dividend policies, have so falsified their bookkeeping as to conceal surpluses, and have virtually confiscated the property of the confiding stockholders by the use they have made of the proxies which they themselves have solicited through the mails, at the stockholders' expense.

While the railroad magnates have been thus engaged, this great country has been maturing in its agricultural and industrial life, and its domestic commerce has been increasing in volume and in value every day. If good railroad men—drawing their salaries, letting the stock market alone, and serving the interests of the general public and the honest investors in railroad securities—had been running the railroads and attending to their business in a proper way, there is not much reason to suppose that the railroads would not also have been developed and improved at an equal pace with the development and progress of the general business of the country. Our great prosperity has not come upon us unawares, and the failure of the railroads to respond efficiently to it is due to the fact that the railroad system has been used for making a set of individuals enormously rich at the expense of the country's prosperity. The 'magnates' have been engaged in getting control of railroad properties through the devious methods of corporation finance, and in unloading inflated securities upon the investing public. The country was prospering, railroad earnings were therefore improving, and the masters of railroad finance managed in one way or another to capitalize this increased earning capacity and to pocket the proceeds. These charges are not to be taken as applying to every railroad line or every railroad financier. But it is unquestionably true that a great part of the recent total increase of the capitalization of American railroads does not represent actual expenditure for improving the roads and their equipment, but rather represents the great game of private financiering, by means of which a set of men have rapidly become multi-millionaires. They have got control of the American railroad system, have bled it unmercifully for their own benefit, and the result is that it no longer serves the practical purposes for which railroads exist.

There are vast networks of railroads in this country where it is a needless expense to print timetables, because there is no longer any such thing as the operation of trains on schedule. There are sections of the country where the railroads are refusing to receive freight for shipment, either because they cannot supply the cars or cannot see any reasonable prospect of having them conveyed to the point of destination. It is true there has been rapid growth of population and traffic in the West, but this recent growth has been nothing like so rapid relatively as was that of the seventies and eighties. The railroads have had plenty of warning and abundance of opportunity to keep well abreast of the development of the country. No condemnation of their failure to do this is likely to be too drastic or to state the facts with serious exaggeration. Even the great Eastern trunk lines, serving a country that has been wealthy and prosperous for two generations, have come far short of showing reasonable foresight and due attention to the strict requirements of a legitimate transportation business. One or two fast trains to Chicago—at the expense of general demoralization of all the remaining volume of passenger business—have been about the only thing to which the managers of these roads could point as an example of enterprise.

Personal.

SAMUEL NEWHOUSE has returned from Cobalt to Salt Lake.

J. R. FINLAY is in New York, where he has decided to reside.

W. H. LANAGAN has returned from a short trip to Tonopah.

J. H. G. WOLF, of Manhattan, Nev., has been in San Francisco.

FRANK J. DAVEY, of Baker City, Oregon, is visiting San Francisco.

F. J. POPE is in Chile, examining mines for the Guggenheim people.

HORACE C. NICHOLS is now manager of the Ymir mine, British Columbia.

GEORGE L. EDDY is at North San Juan, in Nevada county, California.

F. L. MORRIS has opened an office in the Monadnock Bdg., San Francisco.

R. B. BINSMADE is engaged in examining mines in New Mexico and Arizona.

WALTER L. MAAS, of Salt Lake, is examining mines in Inyo county, California.

EDWARD HOOPER has gone to Siberia as consulting engineer to the Orsk Goldfields.

H. A. B. COOKE, of New York, is visiting San Francisco and other parts of California.

W. L. SAUNDERS, of the Ingersoll-Rand Co., is on his way to the Isthmus of Panama.

FREDERIC KEFFER has been nominated the president of the Canadian Mining Institute.

CHARLES C. GATES is the new manager of the Nevada United mines at Ward, Nevada.

C. L. GILSON has been appointed general superintendent for the Giroux Consolidated Co. at Ely, Nevada.

FRANK MCLENNAN, of Cornwall, Ont., has been made manager of the Cerro de Paseo Mining Company.

GEORGE GILL, who has been in the Cœur d'Alene lately, has gone to Sonora, Cal., where he will remain a couple of weeks.

C. B. LAKENAN has returned to California from Philadelphia, and after March 1 he will be stationed at Ely, Nevada.

H. KENYON BURCH, chief engineer for the Moctezuma Copper Co., is at New York, on a visit from Nacozari, Mexico.

FORBES RICKARD, on his return to Denver from a trip to the principal mining districts of British Columbia, has gone to Arizona.

FRANK G. WILLIS, of Cripple Creek, has been appointed consulting engineer of the Henry Adney mine, which recently changed hands.

JOHN T. HODSON and JOHN A. KIRBY, of Salt Lake, attended the annual meeting of the Nevada Hills Mining Co., at Goldfield on March 1.

THOMAS A. VARDEN, of the American Mining & Development Co., has been making an examination of the Uncle Sam mine, at Kennet, California.

HILLS & WILLIS, mining engineers, announce that they have opened an office in the McPhee Bdg., Denver. They retain their former office at Cripple Creek.

J. L. PARKER has resigned as manager of the Brown-Alaska Co., Prince of Wales Island, Alaska. He will open an office at Seattle, Wash., as a consulting mining engineer.

GEORGE A. LAIRD, superintendent of the Copper Queen Con. Co.'s Sierra de Cobre mines, at Cananea, Sonora, Mexico, and formerly manager of La Victoria y Anexas, at San Pedro, Mexico, has resigned his position with the Phelps-Dodge Co., and will enter into the general engineering business with Franklin W. Smith, of Franklin W. Smith & Co., at Bisbee, Arizona.

Homestake Output.

For the first time since its organization the Homestake Mining Co. has issued a semi-annual statement to its stockholders. The report shows that during the last six months of 1906 there was an increase in the values of the ore treated:

RECEIPTS.

From bullion	$2,750 197.58
Other sources	41,017.67
Total	$2,791,215.25
Operating expenses	1,993,680.71
Net earnings	$ 797,534.54
Dividends	$ 665.200.00
Added to surplus	142,334.54
Total	$ 797,534.50

Betterments and permanent improvements, included in and charged to operating expenses, are as follows:

Slime plant construction	$201,097.79
Water system and pipe-line	101,849.01
Sundry items	29,258.19
Total	$332,204.96
Property purchased, charged to operating expenses	$ 7,667.97
Average value per ton	3.818
Tons of ore milled	720,216

Mining Summary.

ARIZONA.

COCHISE COUNTY.

Labor conditions are still unsettled in Bisbee, and no change in the situation has occurred in the last week. About 800 men were discharged in one day, and since then small numbers have been laid off from time to time, many of them men who have been prominently connected with the movement to unionize the miners. It is evident that the mining companies are working out some policy which they have adopted to offset the move on the part of the Western Federation. Just what this policy is, remains a puzzle as yet, but the daily discharge of men at the various shafts seems to be a part of the program adopted by the operators. The merchants have refused to extend credit, and business will soon be done on a cash basis.

GILA COUNTY.

Reports continue to come in regarding the recent rich strike in the Old Dominion mine at Globe. It is said that 40 ft. of high-grade chalcocite ore has been cut by the cross-cut on the fourteenth level, and that no hanging wall has been encountered. Stoping will commence at once, as ore high in sulphur is badly needed by the Old Dominion smelter. The cross-cut has been connected by winzes with the twelfth level, which assures good ventilation. This ore is not a continuation of the west orebody, and lies almost directly beneath the old Interloper shaft, destroyed by fire a year ago. The old shaft was down 1,200 ft., and in 200 ft. more would have cut this orebody. The stock-pile at the smelter contains 10,000 tons of ore, and enlarged smelter capacity is badly needed. A fifth furnace is being added, which will increase the monthly output to 4,000,000 lb. The coke supply is increasing, and immense storage bins for coke and ore will be erected above the smelter, and will be connected by a spur with the company's railroad.

PIMA COUNTY.

Activity continues in the Bunker Hill district, north of Mammoth. The Calumet & Arizona Co. is working 25 men on the Copper Giant group of claims. A diamond-drill hole is down 1,000 ft. and has encountered ore, while on another claim the shaft is down 150 ft. A tunnel is being driven on the Copper Giant, and ore has been struck. ——The Copper Creek mine, which adjoins the C. & A. group, employs 45 men.

CALIFORNIA.

NEVADA COUNTY.

A company has been organized in Boston to operate the old Montana mine in Willow valley, near Nevada City. Some local men are interested in the move. The company will be called the Montana-California G. M. Co., and has both the North Montana and the Montana claims under a long-term bond. The property lies near the Colfax, Murchie, and Lecompton. A new boiler has been ordered, and sinking of the shaft will be continued below the 400-ft. level. It is reported that the mine has produced over $200,000.—— The Gaston and the Ethel mines near Gaston have been closed down, throwing 150 men out of employment. These mines were crippled by the lack of fuel and supplies, and the Gaston has been forced to pull the pumps out of the shaft, but will resume work in the lower tunnel in the spring.——The S. P. Railroad has started the construction of the track from Lincoln to the Dairy Farm mine, and the work will be completed in a few weeks. This will enable that company to ship the copper ore which has accumulated on the dumps.

SHASTA COUNTY.

The Trinity Copper Co. has entered into a contract with the American Smelting & Refining Co., and it is reported that they will immediately commence the shipment of ore to that company's smelters, which are being constructed at Carain, in Shasta county. Trinity ore has a gross value of about $12 per ton, with copper at 20 cents.——The Mountain Monarch mine, 10 miles west of Redding, is being developed rapidly, and shipments are expected in the spring. The ore is being developed through a tunnel.——The Midas mine, at Harrison gulch, is installing new machinery, including a powerful hoisting engine.

High water and muddy roads are delaying the progress at the iron smelter at Heroult, but the rock-crusher has been installed and has started to crush rock for the concrete work. The railroad from Kennett to Delamar, will be completed before the summer is over. It is reported at Kennett that the Guggenheims will take over the Golinsky mine. This is a copper property, consisting of 16 claims, and the Guggenheims have a bond on the group that still has several months to run. A force of 25 men is employed at the property. If this deal goes through, it may mean the erection of another smelter in the Kennett district.

SIERRA COUNTY.

Three shifts are working in the Eldorado mine, near Alleghany; 150 ft. of the tunnel has been finished and in 450 ft. more it is expected to strike the vein. The property is held under bond by H. L. Johnson, owner of the Tightner mine. This claim is situated on Kanaka creek, and on the same lode as the Plumbago mine.

TUOLUMNE COUNTY.

(Special Correspondence).—The Clio Power & Milling Co. has issued bonds for $250,000 preparatory to the resumption of operations at the Clio mine on an extensive scale. Several large orebodies of low and medium-grade ore have been opened up in this property. A recent report was that a 200-stamp mill would be erected.——The Lion G. M. Co. is making preparations to push development of the Ida Klein mine. A branch electric transmission line is being constructed from the main line at Quartz to the property, and a new electric hoist, a compressor and a 150-h.p. induction motor are being installed.——The Sonora and Dutfield mines, situated near the property of the Mountain Mining Co., northeast of Tuolumne, were bonded this week to an Austrian company. The price is $10,000, to be paid within two years.——Berkeley people have become interested in the Clark mine, situated one-half mile northeast of Tuolumne, and a contract will be let within a few days for the sinking of a shaft. Sufficient money has been deposited for development purposes for several months. The property has not undergone much development as yet, but shows excellent indications.——A large body of good-grade ore has been uncovered in the Presiosa mine, situated on the south side of the Tuolumne river, some eight miles above the Mohican. P. J. Maguire, the superintendent, intends running an adit from a point lower than the present workings to tap the shoot, and expects to build a mill on the property in the near future.——The Springfield T. & D. Co., which recently resumed work at its gravel property on Table Mtn., has a promising prospect, and feels confident of rich discoveries within a short time.——There is promise of a revival of operations at the Erin-Go-Braugh, situated near Stent.—— The Dutch mine, at Quartz, will shortly resume operations under the management of Geo. Ade.——A mill and mining machinery was purchased this week for the Bourbon mine, situated above Columbia.——A wagon road is being built to the Ellen Winton mine, where a mill will be erected shortly. Electric power will be used.

Tuolumne, Feb. 24.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Scotis Mines Co. is developing. Another level is being cleaned out and re-timbered, and a good streak of ore is showing in the heading. It is the intention of the manager, Owen Williams, to open up reserves of ore, to insure the constant running of the mill. Machine-drills will be installed.—— An important strike has just been made in the Silver Cloud mine, situated on Sherman Mtn. At a distance of 1,250 ft. from the portal of the Victoria adit this lode was intersected, and after driving west for 70 ft. a body of lead ore was uncovered, one foot in thickness. The ore contains 70% lead, and 90 oz. silver per ton. The ground is to be opened for 200 ft. before a stope will be started.—— A new adit has been started by the Krupp Mining Co. on Saxon Mtn. The bore is to be driven to catch the junction of the Bellmont and Friar Tuck lodes,

which show strong in surface workings. In the upper workings small bunches of ore have been encountered which milled as high as $200 per ton, gold, siver, and lead.—— A big streak of high-grade ore has been found in the Poor Man's Relief mine, situated in West Argentine. The ore-body measures from 8 to 10 in. across, and runs 2 oz. gold, and 60 oz. silver per ton. The ground is being opened preparatory to carrying a stope. W. A. Maxwell is the manager of the property.—— A pool of Idaho Springs business men has taken a lease on a large block of ground in the Bellevue-Hudson mine, situated on Columbian Mtn. A winze is being put down from the upper workings to connect with the tunnel level. A body of ore, measuring six inches in width, is exposed which carries 225 oz. silver per ton. Jacob Widetich is the superintendent.—— A. D. Bryant & Co., leasing on the Bellevue, are shipping high-grade ore. Two cars are sent to the Denver smelters per week. This is one of the best paying leases of the upper Clear Creek district, and the output will be heavy during the present year.—— Operations on the Paris group of claims on Griffith Mtn. are progressing. Driving is in progress on the Paris lode, which was cut 200 ft. from the portal of the adit, and a streak of ore 10 in. across is being followed, which is worth $30 per ton in silver and lead.—— Wm. M. Cooper, manager of the Capital Prize, is shipping a number of cars of ore to the ore-testing works at Denver, to determine the best method of treatment. A 200-ton concentrating plant will be built.—— The Millington mine, situated on Columbian Mtn., is being rejuvenated. Under the management of P. H. Stanhope the works are being cleaned out and re-timbered. Several sets of lessees are at work.—— Report is current that the Pay Rock group of mines on Republican Mtn. is to be bonded and leased to a syndicate of Denver capitalists. The deal will be consummated as soon as the owners, Hendrie & Bolthoff, of Denver, return from their European trip.——The Santiago mine, in East Argentine, is the scene of an important strike. In driving the fourth level a body of smelting ore three feet in width has been uncovered. Shipments are being made to the Santiago mill in Georgetown.—— A deal is now pending for the transfer of the Comet mine, near the summit of Griffith Mtn. This property has produced $1,000,000 from shaft workings to a depth of less than 500 ft. A body of quartz is showing, measuring 10 ft. in width, and mill runs returned 38 oz. silver per ton. Denver men are interested in the deal.—— The East Griffith is outputting concentrate and smelting ore. As the mill is now running on full time, it is possible to break the smelting product which has been left standing for a year. The output from this mine during the present year will be heavy.—— The American Sisters mine, situated on Columbian Mtn., is sending forth a good tonnage of smelting ore. Driving is still in progress on the 275-ft. level of the Headlight shaft, an 18-in. streak of high-grade ore being followed. The returns vary from 167 to 600 oz. silver per ton, with 25% lead.

Georgetown, Feb. 21.

GILPIN COUNTY.

The shaft on the West Calhoun property of the Jefferson-Calhoun company has reached a depth of 300 ft. and sinking has been discontinued. Driving is being done on the 275-ft. level, and connections will be made with the corresponding workings of the Kemp-Calhoun to the west of the shaft, as they have already been made on the 200-ft. level. At the main shaft, the Jefferson, the new steel head-frame is completed, and two 100-h.p. boilers are in place, and an 80-h.p. hoisting engine is being installed.——At the West Whiting mine, on Gunnell hill, stoping is being done on the west 400-ft. level. The ore is shipped by tramway to the Polar Star mill at Black Hawk.——The Aduddell property of the Taawasa company in Willis gulch is being worked by a force of 30 men, through the east shaft, which is down 548 ft. Several lessees are also working.——The Old Town shaft is now 1,670 ft. deep, and three shifts are working to lower it to the 2,300-ft. level, which will enable it to be connected with the lateral now being driven from the Newhouse tunnel by the Hot Time company, a subsidiary company of the Old Town Con. M. Co. Levels have been started at the 1,600-ft. point.

IDAHO.

BOISE COUNTY.

(Special Correspondence).—Herman Day and associates will begin work next spring at the mouth of Lewis gulch, a quarter of a mile above Centerville, and will employ 25 or 30 men. Their operations will be a new departure in the mining field in Boise basin, which has been a producer of gold only, as this company will mine for black sand, zircon, monozite, and platinum.

Spokane, Feb. 16.

SHOSHONE COUNTY.

(Special Correspondence).—Miners working in the cross-cut on the No. 10 level of the Bunker Hill & Sullivan mine at Wardner, famous as the greatest single producer of lead-silver in the world, broke into the shoot of the level above, known as the March stope, a few days ago, exposing an orebody of a value estimated at $50,000,000. The official report of the strike shows the shoot is opening more favorably than did level No. 9, which was the wonder of the mining world because of its length, breadth, and quality of ore. The March stope was proved for more than 300 ft. in length and 100 ft. in width, with 30 ft. of clean shipping ore. The Bunker Hill & Sullivan mine was discovered by a mule owned by Spokane men, who prospected in the Idaho hills several years during the early '80s. Afterward it passed to Jim Wardner, who transferred it 20 years ago to a syndicate for less than $1,000,000. It has payed $8,226,000 in dividends to stockholders in the closed corporation, to date, and the monthly dividend of $180,000 has been paid for years.—— H. Woodward, of Lynn, Mass., representing the heirs of Lydia Pinkham, has bought 600,000 shares of Ajax stock, paying 12c. per share. This gives the Pinkhams and L. W. Hutton absolute control. The mine was shut down a month ago because of lack of harmony among the stockholders, but the transfer of control will mean the resumption of work.—— The Diamond Drill Contracting Co., of Spokane, has taken a contract for 5,000 ft. of drilling in the Snow-storm mine, near Mullan.—— A strike of importance has been made in quartzite on the Hennessy-Burns group, part of which is in Idaho, the other in Montana. A four-inch streak of galena carries 68% lead and 10 oz. silver. It is expected shipping will begin in 30 days.—— The Idaho Spring Gulch M. & M. Co. reports that the lode, nearly horizontal, has straightened and is now vertical. It has been decided to cross-cut the vein to the hanging wall and then run a lower tunnel 700 ft. to cut the vein at 600 ft. The new officers of the company are: Fred Carson, president, and William Coumerilh, treasurer.—— C. A. Pooley of the Morning mine, at Mullan, has secured nine claims, five of which are patented, near the old Iron Mtn. mine, 40 miles east of Mullan. The claims were worked in 1891, and shipped $150,000 worth of ore. The formation is porphyry, quartzite, and slate, the veins are fissures, and one is 40 ft. wide. One vein carries ore running 12% copper, and 50 oz. silver. The other carries silver-lead ore of good value.—— Reports from the Stewart mine, F. A. Heinze's property, near Wardner, are that the property is in excellent condition. The pay-shoots have been opened, and the workings of the mine are in ore. Heinze and his associates own or hold by option 94% of the stock, which leaves only 60,000 shares loose. Of this stock about 15,000 shares are held in Spokane, and 27,000 shares at Wallace. It is given out that that the largest concentrator in the district will be installed.

Spokane, Feb. 22.

NEVADA.

DOUGLAS COUNTY.

(Special Correspondence).—Buckskin is on the west side of Smith valley, 16 miles west of Yerington and 16 miles by stage from Wabuska. The camp is in a low range of hills, the country-rock being andesite and limestone. One of the principal properties is the Kennedy Consolidated, which has considerable development. Gold occurs in the first 50 ft. in depth, below which is a chalcopyrite, running well in gold and copper. W. C. Pitt, W. D. Kennedy, and others control the property. It has six shafts, averaging 70 ft. deep. The Nevada-Bullion, on which a few thousand dollars have been spent in development, has a showing of similar ore.

This is in charge of T. L. Hoppin of Yerington, who is interested with A. D. McEvoy, W. B. Watlington, R. P. Wompler, and F. S. Smith. Other groups being developed are the Mineral Farm, the Burke & McLaughlin, Original Buckskin, and others. Much interest is taken in the camp by Tonopah and Goldfield parties.

Wabuska, Feb. 21.

LINCOLN COUNTY.

(Special Correspondence).—Crescent is excited over the four strikes that have been made during the past week. A. J. Waddleton of the Golden Crescent Co. was the first to report the find that was made in the Syndicate tunnel, where 20 ft. of vein matter was cross-cut, with some copper ore, carrying gold. Following this came the report of the strike on the Old Mexican mine, owned by the Crescent Searchlight Co., where in a winze, 165 ft. from the mouth of the shaft, five feet of ore has been encountered. This property has shipped some ore and is now being developed by G. W. Huntington. The next and probably the richest find was made in the Yaqui mine, situated three miles east of Crescent peak. There are 13 veins traversing this property, upon which some surface work has been done. C. M. White, the superintendent, uncovered a four-foot vein that assays from $17 to $100. The copper strike on the Chilstrom group has also caused excitement. Three samples gave an average assay of $109 showing 20% copper and the balance in equal proportions of gold and silver. Crescent is filled with mining men that are here on a tour of inspection.

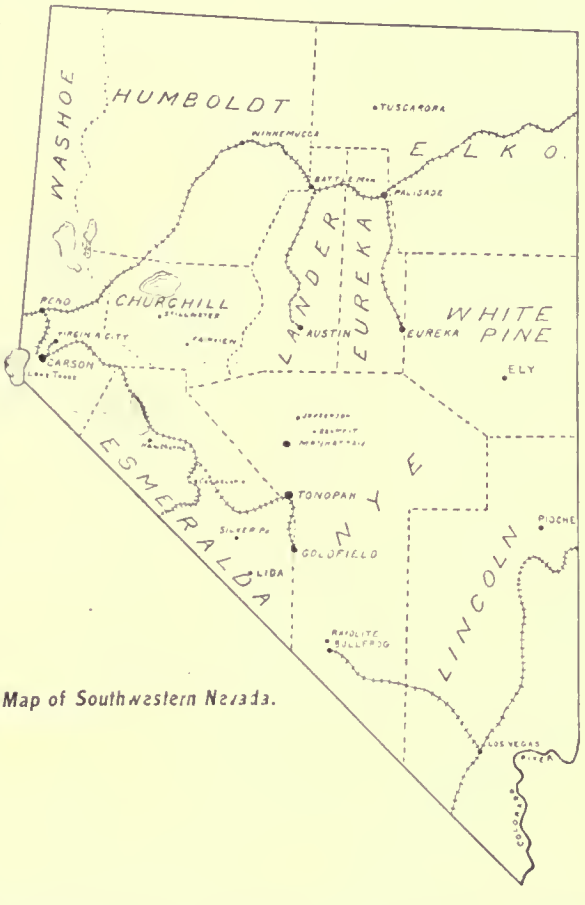
Searchlight, Feb. 21.

NYE COUNTY.

(Special Correspondence).—The new mill of the Desert Power & Mill Co., which is the name of the power and milling concern of the Tonopah Mining Co., is located at Millers station, 10 miles west of Tonopah, on a desert flat, where an abundance of water is obtained from wells, at no great depth. The mill has three crushers; 100 stamps of 1,050 lb. each; five Huntington mills; a 30-ft. and a 54-ft. sand-wheel; a Robins automatic tripper that brings the ore to the battery bins; classifying cones; 20 Wilfley tables; eight vats, 36 by 20 ft., equipped with agitators; four collecting sand tanks, 33 by 8 ft., and 18 leaching tanks, 33 by 8 ft.; also Blaisdell excavators, Butters distributors, and Butters vacuum filters. The ore is reduced to 1½-in. size before it passes to the stamp batteries; 500 tons of ore are reduced to this size in eight hours by the crushers. The battery water is cyanide solution, and 16-mesh screens are used. The pulp passing these screens goes to a series of cone classifiers, being elevated to the classifiers by a 30-ft. sand-wheel. Extra cyanide solution is added to the classifiers for an upward current. The overflow from the classifiers is conveyed to Wilfley tables; the coarse product is re-ground in Huntington mills having 30-mesh screens, the pulp then passing to the tables. The tailing and middling from the Wilfley tables are elevated by the 54-ft. sand-wheel to a set of double cone-classifiers. The overflow from the latter goes to the slime vats and the coarse to the main leaching vats. The tables make a concentrate that runs high in silver sulphide and pyrite. In this work it is expected to obtain one ton of concentrate from each 60 tons of ore passed through the mill. The slime material, after being leached in connection with agitation, is passed to the Butters filters, through which the clear solution comes. The usual form of zinc box is used, with zinc shavings. A complete refining equipment is installed at the mill. The power plant consists of Babcock & Wilcox boilers of 800-h.p. capacity, equipped for both coal and oil as fuel; four Westinghouse electric generators, three of 250 and one of 300 k.w. capacity. This supplies power for the mill, for the company's mines at Tonopah, and for the sampling plant of the Western Ore Purchasing Co. at Millers. F. A. Keith is general manager for the Tonopah Mining Co. and its subsidiary companies; R. Chester Turner is mine superintendent; A. R. Parsons, mill superintendent, and S. J. Kidder, assistant.

The Tonopah-Belmont M. Co., a subordinate of the Tonopah M. Co., is erecting a 60-stamp mill at Millers, and its equipment throughout will be similar to that of the mill above described. Mr. Parsons will also have charge of this mill, W. H. Blackburn being superintendent of the mine at Tonopah.

The Tonopah Mining Co. has cut a station at the 600-ft. level in the Silver Top shaft, and will begin driving as soon as sufficient power is available, its power now being limited by lack of fuel. The company has also cut a station at 600 ft. in the Valley View shaft, and a station is being cut at 900 ft. in the Mizpah shaft. Within the last year a large amount of driving has been done on the Mizpah's 600-ft. level. Extensive building improvements have been made during the past year, including buildings for staff employes, and new head-frames at the Silver Top and Red Plume shafts. A new compressor was also installed.—— Ore production in the Tonopah district has been, and still is, very much curtailed by reason of the fuel famine, and milling operations are greatly hindered. The power-plant of the Tonopah Mining Co., at Millers, is closed down because of the company's inability to obtain either coal or oil as fuel for the boilers. The boilers are equipped for both kinds. The 500-ton mill of the Tonopah Mining Co., at Millers,



Map of Southwestern Nevada.

derives its power from the electric plant referred to, and the mill is idle. Practically all the hoisting is done by electric power at this company's mines, and the shutting off of its own power supply has greatly interfered with the mine work; the company has, however, been able to buy some power from the Bishop Creek, California, plant, but it is stated that the latter's capacity is now overtaxed. Other companies in the district have suffered in like manner, and the effect will be to cut down the year's production. The main cause of all this is said to be shortage of cars, and the unwillingness of the large transportation companies to allow their cars to go off the main lines. Some relief is anticipated for this district and Goldfield as soon as the railroad line now being built from Beatty to Goldfield is finished. Its completion is only a few weeks ahead. This will afford an outlet to the San Pedro and Santa Fe lines to the south, and ought to facilitate the hauling of both coal and oil to this section. The Bodie & Mono Lake Railroad will be connected with Benton station on the Carson & Colorado Railroad this year, which will open up the Sierra Nevada timber-belt to this section. The latter road is now controlled by the Oregon Short Line.

Tonopah, Feb. 22.

OREGON.

BAKER COUNTY.

A rich strike was made at the Alamo, at a depth of 800 ft.——The Kendall and Dearinger leases on the Buffalo are shipping to the smelter.——The Red Boy mine is to be operated again by a new company. This property was a famous producer at one time, but its richest pay-shoot pinched out and some complex financiering of the company resulted disastrously, so that the property passed into the hands of a receiver.——B. S. Schlessinger is the new superintendent of the Standard Con. company.——The stamp-frames at the Columbia mill are being replaced by new material.——The smelter at Baker City has blown in for a short run. More ore is on hand than the amount of fuel available will handle, but it is hoped that by April the plant can be running continuously.

WASHINGTON.

State Coal Mine Inspector D. C. Botting has filed with Governor Mead a report showing the total coal production of the State of Washington for October, November, and December, 1906. His biennial report recently submitted carried the statistics on production to October 1, 1906. This supplemental report shows that the total coal production of the State was 2,846,901 tons for the year 1905, and an increase of about 15½% in 1906. The total production for the last three months of 1906 was 880,412 tons.

CHELAN COUNTY.

(Special Correspondence).—The Washington-Meteor Mining Co. is operating at Blewett, on the east slope of the Cascades, 12 miles south of the Great Northern railroad. It has been developing for some time and reports having four miles of underground work, in cross-cuts and adits, opening three well-defined veins of ore. The equipment consists of a 20-stamp mill, with concentrators and a cyanide plant, the machinery being operated by electric power. The mill will be started in the spring.——The Standard Reduction & Development Co., with offices in Seattle, is planning to erect a concentrator and leaching plant at its property on the Stehekin river, northwest of Lake Chelan. Extensive tunneling is planned. Present work has developed bodies of ore carrying silver, lead, and copper. Much of the copper ore is carbonate and it is to treat this kind that a leaching plant is to be erected. The concentrator will be for the silver-lead ores. S. S. Fluhart, the manager, states that the camp is to be tapped by a railroad which will pass up the Skagit, across Cascade pass, thence down the Stehekin to Lake Chelan.

Portland, Feb. 1.

FERRY COUNTY.

(Special Correspondence).—A new effort is being made to consolidate the mining interests of Republic camp under one ownership and management, on the plan proposed some months ago by Wm. B. Potter, of the St. Louis Sampling & Testing Works, which was to bond and lease the mines, install heavy machinery, and develop them on an extensive scale; the royalty under the leases to be paid as a part of the purchase price; also to install a mill of 500 tons daily capacity. The parties interested are Montana men, who are backed by New York capital and are assured of the requisite method for treating the ores. While the names of these people are witheld, the consideration for each of the mines is said to be greater than was proposed by Prof. Potter.——A large body of arsenical iron ore has been uncovered in the Pin Money shaft, on the Oversight group of claims, which, according to grab samples, will average $1,000 per carload. This ore underlies the oxidized material, which goes down to a depth of about 60 ft. The shaft is down 70 ft., and the body of ore improves in size and value with depth. The Oversight M. & M. Co. is pushing development and employing extra men. About 1,000 ft. of 2-in. pipe has been laid between the power-plant and the Pin Money shaft, and machine-drills are used in place of hand-drills. A gasoline hoist has been ordered, which will be installed by March 1. The vein in the Pin Money ground is distinct from four others on the group, both in character and value, the ore in the former being chiefly gold, while that in the other veins assays less in gold and contains a larger amount of iron. There is a wide difference also in other constituents. On account of the higher value, the Pin Money ore will be hauled by teams to the Washington & Great Northern Railroad, but from the other veins no ore will be shipped until after the completion of a tramway, from the Oversight claims out to the tram. During the past few weeks the Oversight company has been experimenting to ascertain whether the surface oxidized ores on its claims can be treated by cyanidation. E. J. Delbridge, the manager, is preparing to ship several tons of ore to Denver for final testing, and, if the results are satisfactory, the company will install a plant. The result of these tests is a matter of great importance to the neighboring mines in the Belcher district, as well as the Oversight, as there are hundreds of thousands of tons of such ore that may be treated at home at a less cost per ton than that of transportation to the distant smelters.——At 110 ft. from the portal, in the new adit on the Mountain Boy claim, at Park City, a blind quartz vein was recently encountered which has been penetrated six feet without reaching the foot-wall. The ore assays in lead and silver over $40 per ton, the lead being of the most value.

Republic, Feb. 23.

OKANOGAN COUNTY.

(Special Correspondence).—George F. McLeod has acquired controlling interest in the Butcher Boy mine near Chesaw, Wash. The Butcher Boy is one of the leading gold properties in Okanogan county, and was recently operated. It was the first steady shipper in camp. The ore is taken from a four-foot vein on the 100-ft. level and the shipments made last summer and fall to the Granby smelter netted more than $1,000 per car.——Spokane men have purchased the Mistletoe group of three claims in the Twisp district, Wash., the price being $60,000. The claims lie near the Alder group. L. H. Prather is president, and J. S. Pence, treasurer. The claims are traversed by a vein which crops for a width of 150 ft. on the surface.——Strikes of galena were made a few days ago in Old Germany group of claims in the Okanogan district, Washington. In sinking the shaft a vein was opened and a cross-cut showed good shipping ore. A good wagon-road will be built to the mine early in the spring.——Miners from the Bluffton mine, two miles north of Chesaw, report that the vein has been encountered. The tunnel has a depth of 250 ft.——Another strike of antimony has been made in the Dixie Queen mine, near Methow, Wash. The property is owned by the Antimony Queen Mining Co., and during the progress of its development has shown some phenomenal antimony ore. This is the second strike of importance made in this property within six months. Two crews are working, one driving in the tunnel and the other breaking and sacking ore for shipment. Contracts for hauling 100 tons of ore from the mine to Pateros on the Columbia river have been let and ore is being taken down on sleds. A 20-ton antimony smelter may be built the coming summer.

Spokane, Feb. 16.

SKAMANIA COUNTY.

(Special Correspondence).—The Metaline mining district is on the Pend d'Oreille river, 65 miles north of Newport, the latter being on the Great Northern railroad. As a lead district it has been known for 20 years, but progress in mining there has been retarded by the fact that the ores are rather low in lead and contain very little silver. Good progress has been made within the past year, however, by the Metaline Lead Co., Metaline Mining & Smelting Co., Mammoth M. & S. Co., the Lead King Mines Co., and the Larson Lead Co. Development work has opened large bodies of lead ore, and before the end of this year it is believed the district will be a producer. The ores, which are entirely sulphides, occur in two kinds of deposits—in irregular bodies within the limestone, and at the contact of dolomite and limestone. The gangue is an altered limestone. The ores require concentrating before shipment, and it is announced that the Spokane Lead Mines Co. and the Larson Lead Co. will erect concentrating mills this season. Part of the transportation from Metaline district to Newport is by boat on the Pend d'Oreille river.

Spokane, Feb. 10.

BRITISH COLUMBIA.

Lack of cars and shortage of coke are still features at the mines of the district. During the week ending Feb. 16, the Centre Star shipped 1,136 tons; Le Roi, 2,175; Le Roi No. 2, 385; and White Bear, 70 tons.——Le Roi was forced to close down for a few days, owing to shortage of cars. Work in the shaft continues.——The ore-shoot at the White Bear, which was first discovered by a diamond-drill, and afterwards opened by a drift on the 800 level, is looking well and promises to be the best asset of the mine.——The new 300-h.p. dynamo at the Trail plant has been put in operation, and the capacity of the refinery has been increased from 50 to 75 tons per day. Besides ore from Rossland, shipments were received from other mines at the Trail smelter during the week ending Feb. 16, as follows: St. Eugene, Moyie, 345 tons; La Plata, Kokanee creek, 16; Spokane, 73; Ottawa, Slocan, 23; Whitewater, 74; Hunter, 128; Washington, 23; Lorna Doone, 22; Lally, 22; Lone Bachelor, 25; and Northern Light, 24 tons.——Le Roi smelter at Northport is still closed down, owing to a shortage of coke.

In the Boundary district, little ore is being moved, except by the Great Northern railroad to Grand Forks. The Granby mines shipped, during the week, 8,340 tons to the Granby smelter; to the B. C. copper smelter there were shipped 1,800 tons from the Mother Lode; from Emma, 132; and from the Snowshoe, 450 tons. To the Trail smelter from Snowshoe, 450 tons; to the Dominion Copper Co.'s smelter from Sunset, 100 tons; to Nelson smelter from Skylark, 20 tons. The total shipments for the week were 12,322 tons, and for the year, to date, 90,195 tons.——A large party of students from McGill University will visit the British Columbia mines during the summer months.

It is reported in Vancouver that the McGillivray Creek mines, on Anderson lake, will be reopened next season. There is a 20-stamp mill on the property that has been idle for three years, owing to lack of capital. The ore is a free-milling gold-quartz, and two tunnels, each 200 ft. long, have been run upon the vein.——In the Bridge River country the Lorne property has been recently worked, an arastra being used for reduction of the ore.——The hydraulic mines on Alexander creek, 34 miles west of Lillooet, are to be worked extensively. A four-mile pipe-line will be constructed, and all the properties worked under one management.——It is reported that ample funds have been raised to pay off the indebtedness of the Ymir mine. This will mean the immediate resumption of work at the mine, which is already opened to the 1,000-ft. level, and has an 80-stamp mill, and a tailing cyanide plant with a capacity of 200 tons per day. The mine is developed by a series of cross-cut tunnels, drifts, and raises.

MEXICO.

CHIHUAHUA.

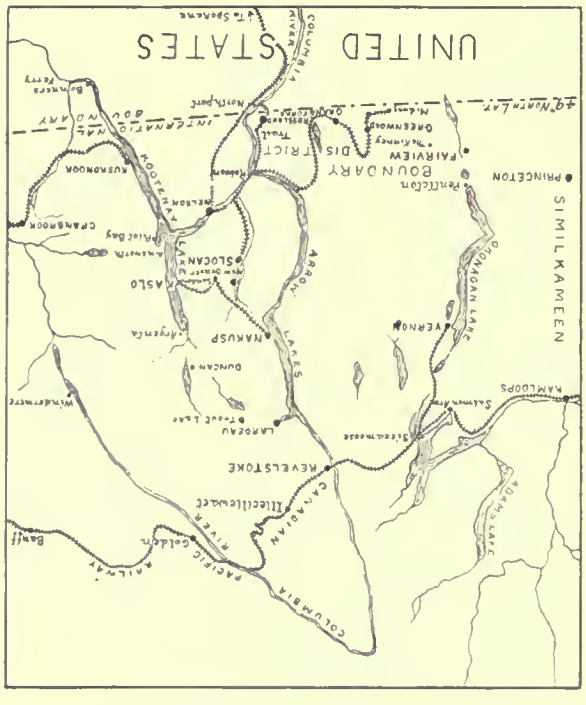
James E. Hyslop is authority for the statement of the affairs of the San Francisco del Oro property, after three years of development under his charge. An ore reserve of 300,000 tons is claimed, averaging 26 oz. silver, 11% lead, and 23% zinc; $375,000 has gone for development, and a profit of $250,000 has been made. Machine-drills are in use, and electric hoists and pumps are in operation. There are three working shafts on the property, and the fourth level has been reached. A concentrating plant will be built, to be preceded by an experimental plant of 50-tons capacity.——The Naica mine, in Chihuahua, paid 50 dividends during 1906, including $312,000, in the last six months. A good body of ore has been struck on the San Antonio, and is being developed. Labor is scarce at this property, which limits the production to about 100 tons per day at present. The company has had as much as 200,000 tons of ore stored, awaiting shipment facilities.——It is stated that the smelter at the Magistral copper mines is to be started. The mines belonged to individuals, were operated by a company, closed down three years ago, and now a new company has taken them over.——During the week ending Feb. 2, the mines of Parral sent 1,820 tons of ore to the smelters, and treated locally 2,175, making a total for the week of 3,995 tons.——The new head-frame at El Tajo mine of the American Zinc Extraction Co. has been completed, and the hoisting machinery should arrive soon. The mine is shipping steadily.——Work on the new power and reduction plants of the Veta Colorado M. & S. Co. is progressing rapidly.

COAHUILA.

A new coal-washer will be installed at the property of the Compania Carbonifera de Sabinos, at Rosita. The output of the mines will be increased to 2,000 tons per day. A railroad has been built from the Rosita to the city of Sabinas, and a contract has been signed with the Mexican Central to supply it with 10,000 tons per month.

DURANGO.

(Special Correspondence).—M. E. MacDonald has been for about six weeks at Topia, Durango, where he and his brother Bernard have purchased a mine. Topia is a beautiful little camp on the Pacific slope of the Sierra Madres at an elevation of about 6,000 ft., and about some 60 miles east of Culiacan. It is a lead-silver camp which has been worked by the Mexicans for years. The ore is a high grade lead-silver ore running from 20 to 40% lead and about 3 kilos in silver. The ore in the veins is from 15 in. to 5 ft. wide. The



Map of Part of British Columbia.

method of treatment is hand-jigging and concentrating the lead, and lixiviating the tailing. The concentrates are smelted in small smelters. In most cases the silver is separated from the lead in the smelters and either shipped to Mexico City or Culiacan. The lead bars and litharge are allowed to remain in Topia. They would pay to ship, but the scarcity of pack-animals prevents them from being marketed. It is expected in the near future that a railroad will be built fromCulican into Topia, but it is expected that they will start soon, as the parties interested in the road are buying up large tracts of timber lands.——Good progress is being made at Guanajuato. There is now a mill of 100 stamps in operation at La Luz. This mill belongs to the Guanajuato Amalgamated Gold Mines Co., which is principally owned by the Al Adams family of New York. A 40-stamp mill on the San Prospero property owned by Mr. Peck of Colorado Springs is in operation, and 100 stamps are working on the Peregrina ores. Mr. Van Law is working successfully his 80-stamp mill on the dumps of the Valenciana and Rayas mines. The Guanajuato Consolidated has its 80-stamp mill in full operation and is, as usual, doing very nicely. In the last three months they have opened up a big orebody below the fifth level in the Sirena, which has $1,500,000 gross ore in sight. This is called the San Francisco ore-shoot. Winzes are being sunk on other orebodies and recently one has opened into ore averaging 4 kilos for a width of 6 feet.

Durango, Feb. 25.

Special Correspondence.

Salt Lake, Utah.

Another Copper Smelter.— Settlement Between Smelting Companies and Farmers.— New Railroad to Ely.— News From Bingham. More Railroad Facilities.

The ore and bullion settlements reported during the past week aggregated $606,600.—— Sidney M. Bamberger, manager of the mining interests controlled by his father, Simon Bamberger, has made the announcement that another copper smelter will be built somewhere near Salt Lake City during the present year. While the plant will be erected ostensibly for the purpose of treating the ores of the Carisa mine at Tintic, and the Fortuna, Bingham Mary, and Argentine mines of Bingham, it will be open to the treatment of custom ores. It is likely that the ores of the Daly-West, Daly, Ontario, and Nailriver mines at Park City, and Ely Witch mine at Ely, Nevada, operated under the management of Ernest Bamberger, will be diverted to the new smelter. The initial capacity of the plant will be 250 tons of ore per day.

Since the American Smelting & Refining Co. has reached an agreement with the farmers that appeared as plaintiffs in the late smoke suits tried before Judge Marshall of the Federal Court, the remaining smelting concerns are negotiating along the same lines with the hope that they, too, may reach a similar understanding, all of which is contingent upon the Court entering a stipulation modifying his late decree. The Court, it will be remembered, enjoined the smelting companies from treating an ore or combination of ores carrying more than 10% sulphur in the charge. The A. S. & R. Co. has shown to the satisfaction of the farmers that with the system of bag-houses and cooling-chambers, which it now has in process of installation, practically all the flue-dust can be saved and the obnoxious gases eliminated to the extent that the possibility of damage to growing vegetation will be reduced to a minimum. The Bingham Con., United States, and Utah Con. companies deem it would be unfair for either the farmers or the Court to discriminate in favor of the A. S. & R. Co.; therefore they believe their case has been strengthened by reason of the compact between the last named corporation and the farmers. In the meantime the matter of concluding arrangements to move elsewhere, or out of the Salt Lake valley entirely, is held in abeyance.

Some strong financial interests are behind a scheme to build a railroad from Salt Lake direct to Ely, Nevada, through the Deep Creek mining district. It is said that the scheme contemplates an extension of the line to Tonopah, in the event that the Brock system does not build to Ely. The primary object, however, is to provide more direct connections with Ely. The line would undoubtedly be a paying one for the reason that it would tap several good mining districts on the way and should capture the bulk of the freight and passenger business between Ely and Salt Lake.

The management of the Albion Mining Co. at Alta is giving consideration to the erection of a concentrating mill. The mine will be a regular shipper of crude ore after May 1. William Hatfield of Provo is president of the company.——The Utah Apex Mining Co. at Bingham maintains shipments at the rate of 100 tons of ore daily. ——Construction work on the plant of the Markham Gulch Milling Co., also at Bingham, is progressing; but delay has been experienced on account of the delay in delivery of material.

The adit being driven in the Phoenix mine, at Bingham, has been advanced a distance of over 2,000 ft. When connected with the upper workings it will become the main avenue through which future operations will be conducted. The mill is turning out about 25 tons of concentrate daily, while the shipments of crude ore amount to about 25 tons. It is the intention of the management to increase the mill capacity.——The statement has come from an authoritative source to the effect that the Rio Grande Western railroad is likely to take steps in the near future to extend its system of tracks into the camp of Bingham. Notwithstanding that it has its second line in the camp practically completed, the management realizes that the development of the mines there has been so rapid that with its present facilities it is a grave question with them if the road will be in position to handle the traffic coming to it; particularly after the new mills of the Utah Copper and Boston Consolidated companies at Bingham get to work.

Tonopah, Nevada.

The Tonopah-Midway Co.—A New Mill for the Montana-Tonopah.— The Tonopah Extension.—Big Width of Ore.—A Mill to be Built. —The Butters Plant at Virginia City.

The Tonopah-Midway Mining Co., for which W. J. Douglas is the general manager, and R. W. Condon, superintendent, is shipping about 100 tons of ore per week to the plant of the Western Ore Purchasing Co., at Millers. This mine has the same system of veins as the Montana-Tonopah. Its main shaft is 835 ft. deep. It was sunk on one side of the orebodies, the latter being opened by cross-cuts from the 435, 535, and 635-ft. stations. The dip of the vein is such that from 300 to 400 ft. will have to be driven on the 835-ft. level to reach the ore. The ores are characteristic of the district, the relative values being about one-third gold and two-thirds silver.

The new mill of the Montana-Tonopah M. Co., at Tonopah, will be completed within a few weeks. It will have three crushers, 40 stamps, eight Wilfley tables, 16 Frue vanners, two tube mills, and a cyaniding equipment, with Hendryx agitators and Butters filters. The first section contains the crushing, grinding, classifying, and concentrating equipment; the second section, farther down the hill, contains the cyanide plants. In this mill the crushing and grinding are not to be done in cyanide solution, as in some of the other mills of the district. The process is one of concentration and cyanidation of tailings. F. L. Bosqui, metallurgist for the company, has general supervision of mill construction.

The main working shaft of the Tonopah Extension Mining Co. has reached a depth of 910 ft., and J. G. Kirchen, the manager, states that sinking is progressing at the rate of 80 ft. per month. The shaft passes through the vein at a depth of 220 ft., the dip of the lode being 48° toward the north. Levels are run into the ore from each 100-ft. station. It is stated that the width of ore varies from 16 to 40 ft. One of the best stopes has 40 ft. of ore. The shipping ore lies along both foot and hanging walls, with milling ore between. That running $20 to $30 per ton is graded as milling ore, the shipping ore running from $30 to $150 per ton. The mine is shipping from 350 to 400 tons per week, all of which is taken from the stopes on and above the 600-ft. level. On the stations below the 600 level, cross-cuts are being driven to the ore. The gangue is quartz and silicified andesite. Tests of the ore have been made, and plans are completed for a milling plant, which will provide for concentration, and cyanidation of tailings. The exact location of the proposed mill has not been determined upon. The plant will have a

capacity of 700 tons per 24 hours. In the meantime the work of blocking out ore goes on at a good rate.

The Virginia City plant of the Charles Butters Co. was erected to treat the material from an old mill-dump, by separating the sand from the slime. The sand was cyanided by the ordinary method, and the slime was treated by agitation in cyanide solution and in vacuum filters of the Butters type. A large tonnage was treated in this way, and while the percentage of extraction was variable, the work proved profitable. For the present this work has been discontinued and the tailing dumps are held in reserve for future work. This tailing contains about four ounces silver, and $1.20 gold. Since stopping work on the tailing this plant has been operated on Tonopah ore, which runs from $30 to $35 per ton and consists of oxidized ores, carrying 30 to 35 oz. silver and $8 to $10 per ton gold. At present the plant is receiving about 100 tons per day. The method employed is stamp-milling, fine grinding by tube-mills, concentration by vanners and tables, and cyanidation of tailing. The new equipment recently installed for this work consists of 20 stamps, vanners, Wilfley tables, and two tube-mills. Stamps and tube-mills operate in cyanide solution. The material from the batteries passes to tables, whose concentrate product runs high. The middling and tailing from the tables are subjected to fine grinding in the tube-mills, the pulp passing through cone classifiers to the Frue vanners. The vanner product and slime therefrom pass to the cyanide plant, where the sand is subjected to straight leaching in the vats, the slime undergoing leaching by agitation and in vacuum filters. The new equipment has a capacity of 150 tons per day. An aerial tramway, now nearly complete, extends from the railroad in town, down to the plant. This will afford quick and cheap transit for ores from the company's bins at the railroad to the mill.

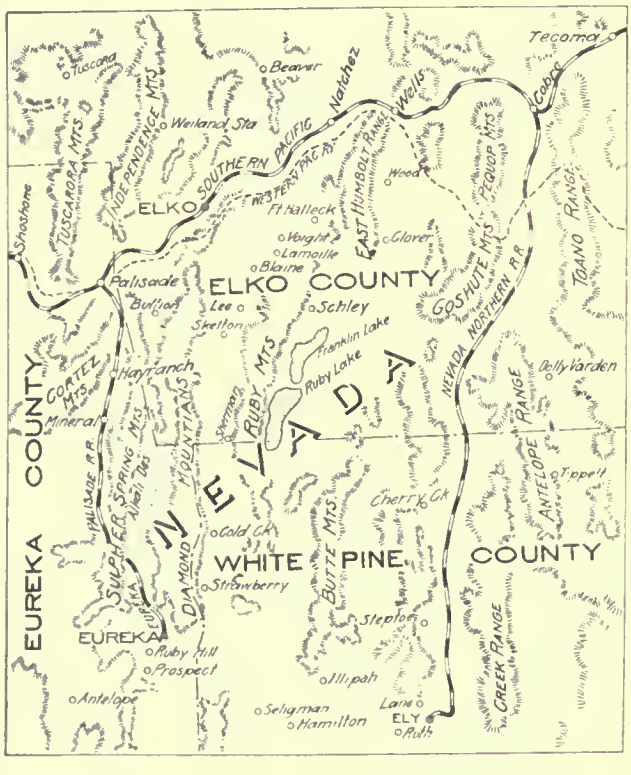
Denver, Colorado.

The Wilfley Mine.—Ore Samples for Schools.—Legislation to Prevent Mining Frauds.—Growth of Public Opinion Against Wild-cats.—The Cripple Creek Drainage Adit.

The recent transfer of the Willley mine at Kokomo to a syndicate provokes more than a moment's passing interest when it is remembered that it was to effect the concentration of the gold-lead-zinc ores of this mine that the owner invented the Wilfley table. The reputation of the table has become world-wide, and the mine still holds its own as a modest producer of wealth.

The Henry Adney mine, at Cripple Creek, has been sold by M. B. Burke to the Equitable Finance & Development Co. Raymond S. Husted has been appointed manager of the property. Several surface improvements will be made in order to increase the shipping capacity of the mine. The shaft will also be sunk to a depth of 1,000 ft., operations at the present time being carried on at the 600-ft. level. This is 200 ft. below the water level of Beacon hill, but this part of the mine has been especially free from water.——A meeting of the Cripple Creek drainage tunnel committee was held on February 21 at Colorado Springs. A resolution was passed to the effect that work should be started at once on the intermediate or Gatch Park tunnel. The assessment work on the tunnel claims is now being done at the portal of the proposed adit. It is intended to use one of the 10-drill compressors belonging to the El Paso Co. pending the arrival of a larger machine from the East.

The smelting plants of Colorado have long been a source of invaluable aid to the mining schools of their own and neighboring States by furnishing checked assay-samples of their ores to be used as test-samples by students. The great convenience of this to the colleges naturally tended to prevent any great effort on their part to render themselves independent of the gratuity of the smelters, and with the passing years the demands upon the metallurgical plants has grown steadily. Finally, an Eastern institution that has recently organized a mining department sent a request for one thousand checked samples; and with one blow slew the goose that so long had laid the golden eggs. The American Smelting & Refining Co. has issued a general order that no more assay samples are to be sent out; doubtless the other plants that have been thus oppressed will not delay in following suit. The schools have only themselves to blame for this development. However proper it may be to obtain, if possible, checked samples to aid in starting a new department, to rely on the smelters to furnish samples continuously, rather than to provide for themselves large lots of ore that will serve for their yearly needs, shows an improvident spirit that is scarcely to be admired.



Map of Eastern Nevada.

The mining fraud bill, which has passed the lower house of the Colorado legislature, and is now before the Senate for consideration, deserves the interest and support of all the serious-minded and honest members of the mining fraternity. The bill in its present form provides that all companies issuing fully paid stock must file with the Secretary of State a complete description of the property thus transferred, giving also the title (whether possessory, fee simple, or leasehold), the name of the party from whom purchased, the actual amount paid, and what proportion of the stock received for the property has been donated to the company. The failure to comply with this law permits a stockholder who believes himself to have been wronged to recover by means of a civil action. The penalty for failure to comply with the provisions of the law may be a year's imprisonment, $1,000 fine, or both. Such a statute would make the operation of the wild-cat promoter much more difficult, and it is to be expected that strenuous opposition to it should develop in certain quarters. Probably the bill will pass, but if it should be defeated in the Senate it is to be hoped that some of the daily papers will be courageous and independent enough to print the roll-call.

The increase of public sentiment against such wild-cat operations is extremely gratifying to all who have the true interests of the mining industry at heart. California and Wyoming already have laws similar in their purport, and have been able to enforce them to a satisfactory degree. Minnesota is urging a law to regulate companies operating in that State and in Nevada; it is proposed to establish a system of district mining inspectors. The mining Provinces of Canada set a wholesome example in this regard. It is most sincerely to be hoped that the final result will be to bring about the extermination of the mining shark, who finds his peculiar habitat in the turbid water of a boom. The mining fraud is a peculiarly despicable kind of a fraud, for in most instances its victims are of a helpless, trusting, and innocent class, such as ministers on infinitesimal salaries, women trying to live on inadequate incomes, uninformed wage-workers, and others struggling against adversity, who deserve to be assisted, rather than preyed upon by sneak-thieves and second-story men masquerading under the guise of promoters. Laws providing for the punishment of such as these can do no harm to legitimate mining, but only aid it, by affording a means of discriminating between the legitimate and illegitimate, removing from the former the cloud of suspicion that often has proved difficult to dissipate.

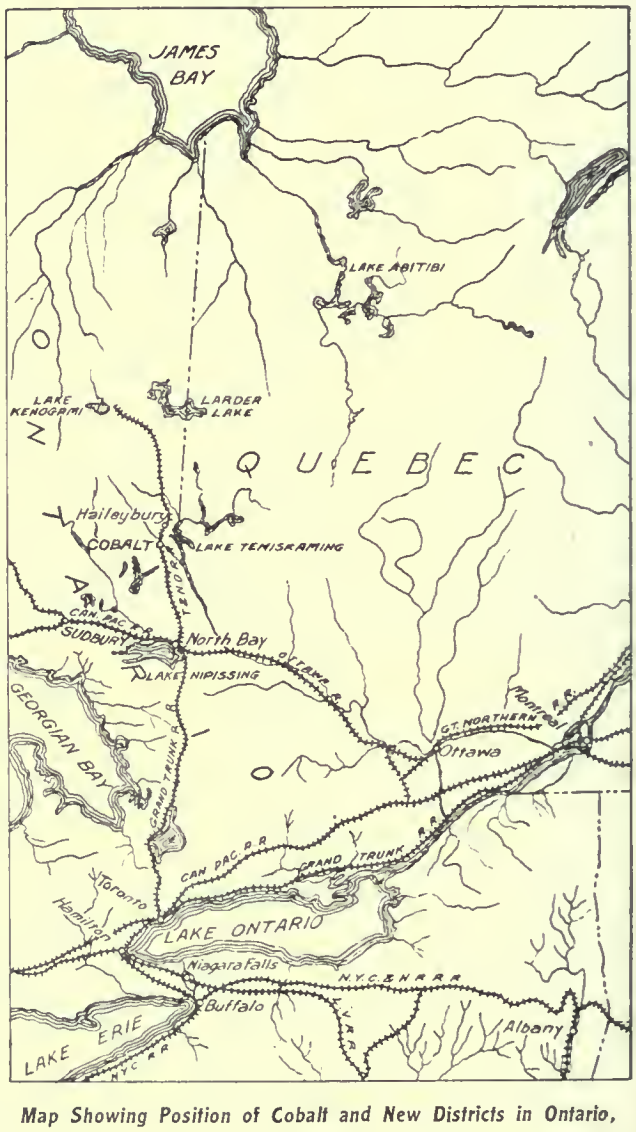
Toronto, Canada.

Shipments From Cobalt.—Annual Output.—Sensational Gold Finds.—New Smelters.—News From Cobalt.—Several Strikes.—Mining Taxation in Ontario.

Shipments of ore from Cobalt over the Temiskaming & Northern Ontario Railways for the week ending February 16, amounted to 187 tons, the following being the shipping mines: Trethewey, 89 tons; Nipissing, 50 tons; O'Brien, 32 tons; Nova Scotia, 15 tons. A report on the present and prospective output of the mines in the Cobalt district by Dr. Eugene Haanel, Dominion Superintendent of Mines, after a personal inspection of the camp made last December, has just been issued. It contains a summary of the ore shipments for 1906, the total being given as 4,584 tons of an approximate value of $4,283,369. The prospective shipments for 1907, from mines at present in operation, is estimated at 12,003 tons of an approximate value of $12,530,152.

Sensational reports having obtained circulation respecting the discovery of gold and silver along the Lievre river, north of Buckingham, in Quebec, Dr. A. P. Low, director of the Canadian Geological Survey, states that the department has received no special information on the subject. A report to the Survey as far back as 1878, records the assaying of a lump of ore, said to be found at Wakefield, 20 miles up the Gatineau, which yielded at the rate of 11 oz. gold per ton; but the fact that it really came from that locality was not confirmed. Since then many samples from that part of the country have been analyzed, in some of which small quantities of gold were found; but in others, none. The Survey officials are not disposed to attach much importance to the reported find, nor to the supposition that gold exists in paying quantity in the Cobalt ores.

It has finally been definitely decided by the North American Refining & Smelting Co., who have for some time been carrying on experimental operations at a small smelter at Hamilton, to build their main plant at Thorold, Ontario, where a suitable site has been secured. They have made arrangements with the town by which the assessment of the property will be fixed at $10,000. The cost of the plant to be erected will be $250,000.——The large smelter of the Montreal Reduction & Smelting Co. at Trout Lake, near North Bay, is nearing completion. It is to be a department smelter and is being equipped with machinery for 12 different processes. In the six buildings erected there is 43,000 ft. of floor space. In the largest of the buildings will be four smelting furnaces each of 250 tons capacity, and a reverberatory. These, it is expected, will be in operation in two months, and later on 10 or 12 other furnaces will be added. Machinery to the value of $350,000 has already been installed. The heavy engines and boilers were made by the Jenckes Machine Co. of Sherbrooke, Quebec, after special designs. Over 1,000,000 lb. of machinery ordered in the United States and Europe is now on the way. The capacity of



Map Showing Position of Cobalt and New Districts in Ontario, Canada.

the smelter is 3,000 tons per day. J. H. Brown of Montreal is manager.

At the Green-Meehan mine, at Cobalt, about 80 men are at work, about one ton of ore being the daily output. The work is necessarily slow, owing to the want of machinery. Boilers are now being transported from Argentine to facilitate operations in the spring. A good strike has been made in No. 3 shaft of the Morrison property, operated by the Cobalt Merger. Development work is being pushed on the properties of the Cobalt Central Mines, Ltd. At the Big Pete the shaft is down 72 ft., and at this level adits 30 to 40 ft. long run into 12-inch diabase, carrying a high percentage of silver. From this mine two carloads of high-grade ore have been shipped. Contracts have been let for sinking four shafts on other properties on which veins have beeu stripped. A power-house is being built for two 150-h.p. boilers and compressors, and a foundation is being prepared for a

concentrating plant to be run by a 100-h.p. engine.——A large slab of practically pure silver, taken from the 135-ft. level of the Nova Scotia shaft, has been brought to Toronto.——The Wabi Cobalt Co. has installed a straight-line compressor with a 3-drill capacity and two 60-h.p. boilers.——Another compressor has been installed at the Buffalo mine, which it is expected will result in a marked increase of shipments.

Strong opposition to the Government's mining taxation policy is being developed. At a meeting of the Toronto branch of the Canadian Mining Institute on February 20, a resolution was adopted, denouncing the measure as opposed not only to the mining, but to the general interests of the Province.

Butte, Montana.

Shaft Sinking by the Butte & London.— The Coalition Co.'s Work. The Big Chimney at Great Falls.— Enlargement of the Smelter. Amalgamated Coke Supply.— Electric Railroad Between Butte and Helena.— The Snowstorm Dividend.— Other News From the Coeur d'Alene.

The Butte & London Co. has adopted the bonus system in shaft-sinking and expects to get good results from it. The average progress made in sinking has been 80 ft. per month, employing 18 men, six on a shift, and paying them $4.50 per day, which is 75 cents per day more than the ordinary wages. The consequence is that the company has been getting the best class of miners and shiftmen. It has now offered them a bonus of $50 for each additional foot over 80 ft. sunk in a month. It is believed that with this incentive the men can make from 90 to 100 ft. per month, and the results will work both ways, that the men will make a good thing out of it, and the company will gain by the decreased cost of sinking. The Butte & London shaft has reached a depth of about 850 ft., and it will be carried to a depth of 1,500 ft. before any cross-cutting is done. Two veins have been cut, and applications have been made for a lease on them, but they were denied, because the company does not want to make any openings on any vein until sinking is completed, lest there should be trouble from water. The prospects of opening a good mine by the Butte & London have been greatly improved by the big strike made in the Berlin claim by the North Butte Mining Co. A vein 28 ft. wide, of which fully one-half is said to be glance that assays 50% copper, has been opened in the Berlin. This vein is pretty certain to strike eastward through the Butte & London ground, according to the best information obtainable.

The recent report that a large vein has been opened in the Coalition's Minnie Healey ground by the Boston & Montana Co. by means of a cross-cut at a depth of 200 ft. below the present workings of the Minnie Healey, is news half a year old. The discovery was made more than six months ago, and was reported at that time in these letters. The Coalition Co. is continuing extensive development work in the Corra mine, the shaft of which is 2,200 ft. deep. Several fine bodies of ore have been opened, and the company is engaged in driving a cross-cut from the 2,100-ft. level north, the intention being to get under the orebodies in the Alice group of mines, now owned by the Coalition.

Work on the foundation for the big smokestack to be erected by the Boston & Montana Mining Co. at the Great Falls smelter has been started, and the stack, which is to be the biggest of its kind in the world, is to be completed in nine months. It will be 506 ft. high above the foundation; it will be circular, in cross-section, and will have a 50-ft. inside diameter at the top, 97 ft. in outside diameter at the bottom, and weigh 16,600 tons. The brick to be used are of perforated radial or segmental form, being made of proper shape to fit the curvature of the circle. The same volume constructed with common brick would require 5,700,000 bricks. One important feature of the chimney will be its sectional lining. When completed this smokestack will have a total height, including foundation, of 742 ft. above the blast-furnace charging-floor, being situated 250 ft. north of the old stack and on higher ground. It will give a draft slightly better than the stack of the Washoe smelter at Anaconda. It will have a capacity of 2¾ times greater than the Washoe stack, and much larger than the present capacity of the smelter requires, but it is the intention of the Amalgamated to enlarge the smelter considerably. The present stack is only 185 ft. high, with an inside diameter of 20 ft. A new flue, 1,800 ft. long, will be built to connect the furnaces with the new stack, and 1,450 ft. of the flue will be 48 ft. wide by 20 ft. high. About 350 ft. of it will be 175 ft. wide by 20 ft. high, this portion being for the purpose of dust collection. The foundation of the stack will be of concrete, 30 ft. deep and 97 ft.

The Coeur d'Alene, Idaho.

across. Preparatory work has also been going on for sometime for the enlargement of the smelting plant. Ground is being excavated for the extension of the reverberatory department, and one of the old furnaces is being removed from the smelter building to make room for the erection of a much larger one. The contemplated enlargement will make it possible to treat about 2,000 tons more ore daily. Should the 'smoke farmers' succeed in closing the Washoe smelter at Anaconda, the Amalgamated would be able to take care of a good portion of the Anaconda ore at the enlarged Great Falls smelter. It is possible that the Amalgamated had such a contingency in view when it decided to re-build and enlarge this plant.

The Amalgamated Copper Co. is conducting experiments with the coal from its mines at Storrs for the purpose of determining whether or not it is suitable for coking purposes, as it is becoming necessary to have a supply of coking coal in the State, instead of depending entirely on Canadian and Eastern points, as at present.

The demand for coke by smelters in Montana averages 1,000 tons every day in the year, while the output in the State, which never exceeded 100 tons per day, has dwindled to almost nothing. Chemical tests of the coal obtained at Storrs have encouraged the Amalgamated officials to believe that the product of these mines is a good coking coal, so a thorough test is being made at Belt. If the experiments are favorable, it is probable that the coking plant will be built at Storrs, and the smelters at Butte, Anaconda, and Great Falls will have a nearer source of supply than at present, while the cost of the coke will be lessened by the shorter distance covered in its transportation. The smelters of the State have been running short of coke for some months, and the supply has been very uncertain. Some of the smelters were not able to run full time because of the coke shortage during the past three months.

It is probable that the proposed electric railway line between Butte and Helena will be built. All the stock necessary for preliminary work has been subscribed. F. Augustus Heinze is largely interested, and the project is considered favorably by local mining men. It is proposed to tap several mining districts between Butte and Helena, and also to build a large smelter on Lake Hauser, near Helena. It is the intention to run ore-trains from Butte to the Helena smelter and make a market for the surplus ore, and also make it possible for small producers to get a better smelting rate than they have been getting. The company is to be known as the Helena & Butte Electric Lines Co., and is to have an actual working fund of $2,500,000. Many good mines and promising prospects are idle in the districts between Butte and Helena because of a lack of transportation facilities, which the proposed road will supply.

The Snowstorm Mining Co. has declared a dividend of $45,000 for February, being the second dividend of that amount since October. The company is capitalized for $1,500,000. The February payment is the beginning of what was expected to be a regular monthly dividend, though it is not certain that one will be declared in March, owing to the fact that bad weather tied up operations for 15 days at the mine, and also blockaded traffic on the Northern Pacific railroad so that no ore could be transported. At the time the dividend was declared there were 190 cars of ore on the tracks awaiting transportation to the smelters. It is reported that the property is in better condition than ever, and that the ore-bodies are developing satisfactorily with depth. The west drift on No. 3 level is expected to break into the orebody very soon, as the entire face is well sprinkled with ore. A contract has been awarded to a drill company to do 4,000 ft. of exploration work to the east of No. 3 adit. Four different bores will be made, one to the length of 1,200 ft., and the country east of the fault will be thoroughly explored. W. D. Greenough, the manager, believes that the work of the diamond-drill will result in finding the orebodies and making the development work more certain.—— Another strike has been made in the Stewart mine, another Cœur d'Alene property, under the control of F. Augustus Heinze. The Stewart is situated near Wardner, and Mr. Heinze secured control of it several months ago by taking an option on 700,000 shares of stock at 40 cents per share. The strike is the second made in the property since Mr. Heinze has been doing the exploration work, and he has announced that he will take up the option when it becomes due. In the course of development work thousands of tons of ore have been taken out and are on the dump, but under the terms of the option this ore cannot be shipped. It is stated that Mr. Heinze has plans for the erection of a concentrating plant on the property.—— The recent work done in the famous Bunker Hill & Sullivan mine at Wardner indicates that the Cœur d'Alene lodes persist in depth. The ore-shoot has just been cut at a depth of 3,000 ft. on the dip, and it is claimed that there is $25,000,000 worth of ore assured.

London.

Good News from Dolores.—Siberian Mines.—Lots of Pups.—Legal Requirements in Siberia.—An Alluvial Enterprise.—Copper in Caucasus.—South Australian Mines. Death of Thos. B. Bewick.

The Dolores (Mexico) appears likely in the near future to outstrip its milling capacity. A study of the reports shows there is the probability of a new ore-shoot north of the one opened up. According to a statement issued this week by Dolores, Ltd., the manager has hopes of finding two veins going down from the 3rd level, where only one was supposed formerly to exist. Then there is the old San Francisco vein, toward which a cross-cut is being run from the 3rd level, with about 100 ft. more to drive to intersect the vein. Now comes the news that a 'rich strike' has been made in the front of this cross-cut four feet wide, assaying $45 per ton, besides a thin streak running to $280. The statement refers also to the slowness of development work generally in the mine as arising from lack of transport for wood fuel, this having put the air-compressor out of work. Regarding the mill, the consulting engineer, Mr. Geo. A. Schroter, states that the plant is treating 50 tons per day by cyaniding. They have been able to bring the mill up to this capacity by utilizing the sand plant, which has been put into commission, and also by utilizing the pans for fine grinding. Mr. Schroter says this is a make-shift, pending the arrival of the new tube-mill. From the surplus accumulated last year and the current profits, it is thought Dolores may be expected to pay quarterly dividends this year at the rate of 20% per annum on the increased capital—£396,000.

The latest circular of Siberian Proprietary Mines Ltd. has not had the effect of restoring the stock of the parent company and its subsidiaries in public favor, although the bottom in prices appears to have been reached for the present. The circular states that it is wholly inaccurate that the company has registered six additional subsidiaries, each with a capital of £100. It is equally inaccurate that the Proprietary Company has off-loaded its Troitzk Goldfields shares at exorbitant prices. The Proprietary Company's original holding of 251,000 shares has been neither added to nor diminished, nor is there any intention of dealing in any way with this interest. The statement that another property was substituted for the one which formed the substratum of the Proprietary Company is altogether without any foundation, the property in question being the one which has been purchased outright by the Troitzk Goldfields. The lease and option to purchase the property that the Orsk Goldfields was subsequently formed to acquire was obtained by the Proprietary Company in the ordinary course of its business. In this case also the Proprietary Company retained a majority holding of 251,000 shares, which has been neither added to nor diminished. With the exception of the transactions stated, the Proprietary Company has not in any way dealt in the shares of either of its subsidiary concerns. The present available cash resources of the company are about £215,000 (mainly from the recent issue of new stock at a big premium), the whole of which is employed either on bank deposit or in short loans upon gilt-edged securities. The issued capital of the company is £116,000. There is not at present in Russia a law relating to joint-stock companies which is general in its application, and the process of complete legalization takes

some little time. The authorization is already complete in the case of the Orsk Goldfields, and completion in the case of the Troitzk Goldfields may be shortly expected. Meantime the returns from the Orsk mines continue to be of a meagre description. The manager reports that in the month of December, 1906, 1,263 tons of tributers' ore yielded in the mill 696 oz. retorted gold; also, during the same period, 30 oz. alluvial gold were obtained from the Suvunduk and Siberian claims. The total revenue to the company from the tributers for this period, after deducting the working expenses of the mill, is estimated at £1,181. It should be noted that during this period, as in previous months, there were only 24 working days. Permission, however, has now been obtained from the Russian Mining Administration to work the mill throughout the year, Sundays and holidays included.

At the statutory meeting of the Kaneika United Goldfields, Ltd., a company which has no connection with the Siberian Proprietary group, and which must be considered as on an entirely different footing as regards its inception and management, the chairman, Mr. H. D. Boyle, in the course of a lucid address, made a statement clearly setting forth his company's position as to titles. The particulars are of interest to would-be owners of mining property in that part of Siberia. He said: "With regard to mining properties on the steppes, where our properties are situate, in order to enable such properties to be worked, and the full benefit thereof to be secured, three things are necessary: Firstly, a transfer of the properties from the owners, whose title has to be investigated; secondly, after such transfer the deed of transfer should be registered with the mining officials of the district; thirdly, under a local regulation passed in 1902, and which was passed with the object of preventing mines which were close to the Chinese border being acquired by Chinese subjects who had not sufficient capital to work them, a formal permit should be obtained to work such mines." Undeterred by the slump in Proprietary flotations, strong groups in London are engaged in the examination of gold mining properties in Siberia, one or two of which at least appear to be of a decidedly attractive character. According to rumor, one of these, situated to the north of Lake Baikal, is shortly to be placed on the London market under sound auspices. The mine in question is said to be a gravel deposit of great extent, worked by a Russian company of good repute for many years with highly satisfactory results. The development is reported to be well in advance of output, the net value of ore 'in sight' being stated at between one and two million sterling. Supposing the facts to be approximately near the figures shown to a chosen few who are invited to come in to the deal on bedrock, the formation of this company should go a long way toward rehabilitating the position of Siberian enterprise, which, it must be owned, badly requires a stimulus just now. In another part of the Russian Empire considerable attention is being given to copper mines, the import duty enhancing the value of the metal by some $160 per ton, being a favorable feature. In this connection the Caucasus Copper Co., Ltd., is likely to give a good account of itself before long, after several years of uphill work, the difficulties having been accentuated by incompetent management during the early stages. Although the expenditure has reached a sum of close upon half a million sterling, the production of copper has not yet commenced. Judging from the latest reports, however, the 500-ton plant, erected under the supervision of American engineers, is nearing completion, and the company will be in a position in the spring to begin turning to profitable account the 3,600,000 tons of ore said to be actually 'blocked out.' Besides these resources for a large output, the mine is considered to have additional possibilities as the result of further important developments over a large area of productive ground. The company has enjoyed the support of such princes of finance as the Barings and Morgans, and the rich experience of the United States has been drawn upon, in the designing of the treatment plant, which includes a magnetic process for the recovery of copper, said to have been in operation for some time in America with complete success on a commercial scale. The mine is 40 miles from the port of Batoum by road, the oil for fuel purposes being conveyed thence by pipe-line.

South Australia, which is credited with an output of copper to the value of over twenty-two millions sterling, is again coming to the front as a producer of the metal consequent on the improvement in price. Among the properties introduced to the London market from this part of the world, the Union Consolidated Copper Mines of South Australia has been able to take a prominent place. When it first made its appearance some remarkable estimates of the value and possibilities of the company's property were put forward, officially and unofficially, and according to accounts these are being borne out by developments. The outputs during six consecutive weeks to the end of December are reported to have risen from 225 tons to 1,150 tons, separate parcels of ore averaging from 6 to 40% copper. Through the acquisition of the Daly mine, which has an area of 80 acres, the company obtained a sixth lode, and it is stated that immense bodies of highly payable ore are being developed on this and lodes No. 4 and 5. The lodes outcrop boldly, the No. 5 main outcrop being about 2,500 ft. long, averaging 200 ft. in width and 100 ft. in depth, while the No. 6 is 2,400 ft. by 100 ft. by 350 ft. The smelters belonging to the company are inadequate for the treatment of the quantities of rich ore that are reported to have been opened up, and arrangements have been made with the Tasmania Copper Co. whereby they agree to erect, at their own expense, a plant capable of dealing with 3,000 tons weekly of the Union Consolidated Co.'s ore. Taking this quantity at 6%, the annual production of copper would amount to 9,000 tons, of the value of nearly £1,000,000 on the basis of the present price for the metal. The working costs are estimated not to exceed 50%; on the contrary, it is supposed they may be much less, as huge bodies of the ore are to be mined by simple quarrying. The Union Consolidated Co.'s mining area covers a trifle less than a square mile, and in view, also, of the extent of the property a subsidiary company has been formed. This is called the Lyndhurst Copper Co., having a nominal capital of $200,000, the shares of which are now being introduced on the market, and it takes over the No. 6 lode entirely. The latest output from this lode is reported to have amounted to 550 tons of 7% stuff.

The sudden death from a broken blood-vessel, is announced of Mr. T. W. Bewick at the age of 50. Men of the last generation will recall the stalwart genial presence of his father, Mr. Thomas John Bewick. In those days the names of Bewick and Sopwith stood for all that was best, more especially in lead mining and smelting. In these days the firm of Bewick & Moreing is no less known the world over, in a much wider sphere of operation as a leading—if not the leading—firm known to English mining engineers and investors, comprising in its members thoroughly up-to-date and successful men in all branches of the industry. The head of the firm, Mr. C. Algernon Moreing, naturally feels keenly the loss of an old partner, as well as a friend and companion from the time when as a young man he joined hands with Mr. T. B. Bewick under the guidance of that gentleman's honored father.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

'BORRASCA' is the reverse of 'bonanza,' and is used to describe a mine which has a vein, but no ore.

A HEAD of water is the service from which hydraulic motors derive their energy; these motors are the most efficient of all prime movers, utilizing about 80% of the units of work stored up in the head of water.

GILSONITE and elaterite are asphaltic minerals that are found chiefly in Utah and Indian Territory. They are mixed with other asphalts, and are used for street paving. The price varies between $30 and $45 per ton.

LOOSE aggregates of rounded and water-worn pebbles and boulders are called 'gravel,' and when they become cemented together into coherent rocks, they form 'conglomerate.' Silica, calcite, and limonite are the commonest cements.

'LACCOLITE,' a name based on the Greek word for cistern, was suggested by G. K. Gilbert for those intrusions of igneous rock that spread out laterally between sedimentary beds, like a huge lens, and that never reach the surface unless exposed by erosion.

A 'WHIP' is a pulley erected over the shaft, the hauling rope passing underneath a second pulley at the surface, and being drawn by a horse walking along the ground. This appliance is most advantageous in sinking prospect-shafts to a depth of from 100 to 200 feet.

THE treatment of serious burns received around smelters, etc., includes generous applications of carron oil, a mixture of linseed oil and limewater, or a solution of sodium bicarbonate. The affected part should be covered with antiseptic absorbent gauze, kept in place by bandages.

HORSE-POWER is the standard for computing the work of living agents, as well as work done by steam engines. It is customary to use 33,000 units of work as an equivalent for one horse-power, but the work of an average draught-horse is more nearly represented by about 22,000 lb. raised one foot in one minute.

TIMBER used for underground supports should be long-grained and elastic, and at the same time light. Oak, beech, and similar woods are strong and durable, but are heavy to handle, and when once they take weight, are treacherous, as they break without warning, being short-grained and inelastic. Pine and fir are good mine timbers.

RAILROAD CURVES are simple, compound, or reverse. Simple curves have but one radius, a compound curve is continuous and has two or more radii, and a reverse curve is a continuous one composed of arcs described in opposite directions. These curves are designated by the number of degrees in the angle at the centre, subtended by an arc whose chord is 100 ft. long.

A COMMON LUBRICANT for wire rope is a mixture of Stockholm tar, tallow, and resin. It is a poor substitute for pure mineral oils or greases, because the tar always contains acetic acid; the tallow becomes rancid, and then contains free organic acids. The Stockholm tar is the worst ingredient, for it sometimes contains as much as 10% acetic acid. Good lubricants are plentiful, so that this home-made mixture had better be discarded.

HIGH-GRADE FUORSPAR is used for the manufacture of opalescent glass, for agate enamels, and the production of fluorine chemicals. Poorer grades find use in the manufacture of open hearth steel and in foundry work. The use of this material in foundries is much less than it ought to be, on account of lack of knowledge regarding it. Extra clean castings are made with its use.

ON THE BASIS of equal weights, sodium, calcium, potassium, aluminum, and magnesium all exceed copper in their relative conductivity. The conductivity of sodium is three times greater than of an equal weight of copper, but it must be protected from air and water, which can be accomplished by filling wrought iron pipes with molten sodium. The cost of a sodium conductor made in this way would be less than half that of an equivalent one made from copper.

A THREE-COMPARTMENT vertical shaft was sunk at the Helena-Frisco mine at Frisco, Idaho, from the 600-ft. to the 1,600-ft. level, in 516 days, at a cost of $59.52 per ft. for labor, material, and supplies. The labor account showed a total of $43.10 per ft., and the total for supplies was $16.42. The chief item, of course, was the labor of sinking, amounting to $28.69 per ft., while the labor for timbering was next, being $5.20 per ft. Fuel supply cost $4.92, and timber $4.64 per ft., powder $2.82, and fuse $0.66 per foot.

IN DRIVING a tunnel of a large size the American centre-cut system of drilling holes has been found efficient, using air at 160 lb. pressure. In this system, the plunger and cut-holes are fired first, then the side and back-holes. The cut-holes require about 100 lb. of 60% gelatine powder, and the side and back-holes from 50 to 70 lb. of 40% gelatine powder. It is not necessary to tamp the holes, and the round can be cleanly broken with from 100 to 170 lb. powder. Tunnels have been driven in this way at a total cost of $28 per foot.

THE VEIN of metallic arsenic one metre wide in Mexico ought to be worthy of exploitation; the operator should balance his costs of mining, freight, and treatment against the market price. White arsenic (arsenious oxide) is worth from 3 to 3½ cents per pound. Most of the arsenic produced in the United States comes from the Everett smelter, which treats the arsenical pyrite of the Monte Cristo mines in Washington, and the Anaconda smelter, where the flue-dust from the furnaces is collected, and the arsenic oxide separated, to be refined previous to shipment in barrels. In 1905 the United States produced 1,545,000 lb. white arsenic, an increase of 55% over the production of 1904.

SCHEELITE, the tungstate of lime, can be treated directly in the electric furnace, together with iron ores, for the manufacture of ferro-tungsten. The lime is valuable as a flux to combine with the silica in the ore to form slag (the preparation of sodium para-tungstate suggested by an enquirer is undesirable). If the ore be associated with quartz, a concentrate could be made and the residual quartz would readily combine with the lime. Any excess of sulphur as sulphide should be avoided, though as much as 2% sulphur is not detrimental, as the de-sulphurization will be complete before the complete reduction of the iron is finished. The cost of a small electric furnace for the manufacture of 20 to 30 tons of ferro-tungsten per day, should not exceed $5,000 to $10,000, exclusive of power plant.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

A Comedy in Three Parts.

The Editor :

Sir—Some time ago I had three reports on a tin proposition submitted to me by prospective investors, requesting that I examine same for their account. One of the reports was from the inspired pen of the promoter, another was from a "practical" miner, and the third from a "well-known" mining expert, so the promoter said.

After reading the three reports carefully, I had to recommend that no further attention be given to the property, for I did not wish to be the means of bringing a property into being, that in all probability would glut the market with tin, causing heavy losses to existing industries. As these papers are unique and interesting, I take pleasure in sharing them with the profession at large; and then, they may serve the younger members as models—to be avoided.

Of course they are compiled, but what extracts are given, are verbatim, the orthography and construction being unchanged.

The promoter said:

"I cannot go into details of the geology; the lodes are too great and valuable. To see them, staggers the intelligent observer, to catalogue them is impossible. The mine is in the midst of a mineral belt containing some of the greatest tin deposits of all history. The predominant out-cropping in the mineral belt on which this group is located, is an andesite,—an igneous rock of an acid type, and of a comparatively late period. These flows cover rhyolite flows of an earlier period, and are in turn cut by basic of an earlier period than themselves. Then I find all this strata lying between green stone and synite granite, carrying more or less tin, or give evidence of having been through the rocks at some earlier period. These latter, undoubtedly, had some considerable influence in the formation of tin deposits, causing by their intrusion stresses, which resulted in a strong fissuring and breccation of the older andecite flows. These lodes follow the general direction of the uplift. These facts indicate that the vein is a true fissure. The dip is toward the East and is almost vertical; this is important, for as a rule, the veins are richer when nearer vertical. The ore chutes dipping to the East. The line of fissure is marked by more or less gossan.

The developments are exceedingly meagre as yet, and consist chiefly in building roads in to the property, and trails up to and around the vast tin deposits, standing in evidence developed by Nature. There are millions of tons of ore in sight. Nature has placed her sign-board pointing to the hidden wealth. My advice is, that the seeker for these treasures follow the path she has marked out. All needs be done is quarry down the mountain of ore. While I cannot estimate the tonnage in sight, I can truthfully say that it is almost beyond figures.

There is a cross-cut tunnel forty feet, all in ore. The ore, from assays, runs about 4% tin; also a small amount of gold and silver. We have verified the correctness of the theories of mining experts in this district, that the lodes increase in richness as they descend. With greater depth in to the mountain, the gold values will increase. Here the great values of the mine will be found. You could work almost a life time on the ore in sight and scarcely make an impression on the vast tonnage.

The general impression that the miner is oversanguine and visionary and impractical, is not sustained by facts; he sees the harvest as clearly as the farmer, but a narrow skepticism would prevent either from reaping. Mining has passed a long way beyond the stage of experimentation; the trained eye here discovers the ore, and experience, skill and science find a larger field in mining than in almost any other calling of life."

The "practical" miner said:

"At a point quite a distance from the foot of the trail—perhaps a mile from the river—brought me to the southwestern boundary of eight claims. From this place, a deposit of ore, which nature itself has developed, stands forth full in sight and can be traced through the entire location in a south-western and north-western direction, with an inclination of a few degrees to the northwest, while it runs up through the mountains to an unlimited height. This massive deposit seems to have sections or lodes, side by side, with ribs of silicious spar running parallel throughout. Taking the width of the whole body, it will measure more than five hundred feet.

As I have tried to give you a glimpse of its dimensions, I will now describe the nature of the ore. The gross body is a micaceous iron. Although much of it has a bluish-black appearance, still it may be protoxide of iron. Its specific gravity is great, and where mica less abounds it is brighter and heavier. And whether broken from surface rock or taken from under cover from one of the prospect holes, its character is the same.

From those claims, I brought away many pounds of ore from various places, and have compared the pieces carefully as to their relative affinity, while at the same time I have aimed to find from each something new in itself; i. e., the grain of lamella, the dull or glittering, the light or heavy weight, and with a greater ardor still, to find some deeper hues of oxides with the existence of richer ores. Having spent much time over this, I, at last, found some cassiterites of tin; and after making many water tests as to the existence of such, resolved to have it assayed. The result was 3.9/10% tin; Gold, $1.12; Silver, 11 cents per ton.

For sometime I found great difficulty in bringing the cassiterites to the head of my washings, and from the practical knowledge of tin dressing, I eventually overcame such. And using as a comparison, tin ores from Old Mexico and from Cornwall, England, and some from the noted Temescal mine, and other pieces from the tin properties of Southern California, it assisted me greatly in their relation to concentrate my researches to the feasibility of produce. While experimenting on the different kinds or quality of rock, as to its degree of value, and from some places of its great deposit, I can find ore that will yield a result of not less than 8% tin.

Having shown forth in few words the dimensions of this tin property of 180 acres, and the test of its value, so far as specimen of assays demonstrate, I will now add my opinion, or as it may appear, advise, pertaining as to the best method that can be used in order to prove whether it can be made a commercial enterprise.

For many years the southwest has been in this great research, not merely from any suggestion, but from the knowledge of the existence of this valuable ore, insomuch that produce has been the result of efforts made in one or two instances; and now, at the present time, tin worth nearly $600 per ton, and the United States of America uses 60% of all the tin that is produced. Therefore such promulgation strongly favors the impetus for such aggrandizement.

From other information in conjunction with my own work, I will say that the only proper thing is to give this ore a commercial test, i. e., take a quantity of many pounds, crush and dress it according to the discretion of those who rightly understand their work. Let it be treated in such a manner as though it were a hundred

tons. They, of course, will observe the specific gravity of it, and also the size of fineness to which it has shaped itself; knowing it is impossible to dress tin ore from one common concentrator. I am not able in this short report to give an idea of the many ways in which the tin is saved; only to impress this: that in such ores as our southern deposits of micaceous substances, it will necessarily require a graceful motion of flow, instead of heavy force of water.

My latest investigation of the Cornish tin dressing has opened my convictions, that while we seek but little or no aid in the pursuit of mining in general, we yet may submit to one favor at least from those who have had an experience handed down from thousands of years. So in conclusion, I will repeat my words, that this is the only advisable method that I can give you whatever."

The "well-known" expert said:

"The structural geology of the property consists of a number of contorted anticlinal folds, with a general trend from East to 22° North of West and with a general elevation above sea-level (mean datum) ranging between 1861 to 2388 feet.

The lithological character of the rocks exposed consists principally of Hydrous rocks of the lower Cretaceous epoch down to the older and more silicious Bisilicates.

The surface rocks are for the most part nonconformal and as a rule carry no values, and for this reason, the development should be confined to the lower levels and the northeasterly strikes, for the present, as the more conservative proposition. Develop the brown, black and yellow granular ores only as they will give the best returns and generally prove the most satisfactory.

Formula for Smelting—first concentrate and take 1 part ore, 2 parts soda (carbonate), 3 parts cyanide of potassium, 3 parts of blacksmiths' coal and saturate the whole with crude petroleum and smelt.

With a careful study of this ore and a frequent test of the samples as the development progresses, you will soon become familiar with the best class of the cassiterite ores and the other details necessary to successful operation.

Taken as a whole, the property looks promising, and we feel warranted in recommending it for a thorough exploration on conservative plans, using good judgment and careful consideration under all conditions."

Are these to be considered parts of a comedy or do they presage a tragedy?

E. A. H. TAYS.

San Francisco, February 10.

Deep Level Development on the Rand.

The Editor:

Sir—From news lately received from the Rand it is reported that a commission has been appointed by the Government to enquire whether the section at present standing in the Mining Regulations and which calls for the sinking of two separate shafts for each separate mine is, or is not, necessary.

The significance of this to shareholders in 'deep level' companies, may not be immediately apparent, as it is somewhat of a technical nature. It should, therefore, at once be explained that the cost of sinking a single shaft to depths of several thousand feet, requires an enormous expenditure of capital, amounting frequently to from £100,000 to £200,000. It is, therefore, at once evident that should it be found that this large expenditure of capital is required in the sinking of only one instead of two shafts, 'deep level' companies should occupy a far better financial position than they do at the present time.

Under the English Coal Mines Regulation Act, two shafts or outlets to any colliery are required in case of accident, as they are subject to explosions of gas, and many years back a terrible accident was caused, resulting in the entombment of a large number of miners, through breaking of a large pump-beam working over the shaft, which falling, dragged in the sides and entirely blocked it up.

Now, as it is well known the Rand gold mines are not subject to such disabilities—there being no gas, and heavy Cornish pumps are not employed—therefore the only other question that need be considered, is, whether an adequate supply of good air for the miners is available through a single shaft; this can be done easily by means of a partition and the employment of mechanical ventilators or fans.

It is further argued, that in most cases an additional outlet of escape for the miners, in case of any temporary accident to the single shaft, can usually be effected by connecting adjoining 'deep level' areas underground by means of drifts; and this could be carried out at a comparatively small expenditure of capital. Thus the cost of driving such ventilating levels would probably only be some £5 per foot, whereas the sinking of a shaft might easily amount to £25 or £30 for every foot sunk.

In view of the great shortage of available unskilled labor on the Rand, 'deep level' companies might easily hesitate to face the great expenditure entailed by the sinking of two distinct shafts, say, with equipment, running into half a million sterling, as after sinking the shafts it would then become necessary to employ a much larger number of unskilled natives or Chinese to carry out the further necessary underground development work. If, however, this commission decides that 'deep level' companies can be safely worked by means of one shaft, then doubtless the directors of such concerns will give the word to start sinking operations on many properties, which are now either only sinking one shaft, in a half-hearted manner, or in which no sinking work whatever is being done, while a large amount of capital is locked up, and is not paying any adequate interest to shareholders.

Those who are following the political situation, now being fought out in the Transvaal and have read the speeches of the candidates, must be convinced that nearly all of them seem to be of the opinion that Chinese labor must at least be retained, (another ordinance being passed to permit of it) until such time, at least, as some fit substitute has been found to take its place.

There are many who feel assured that finally even the Boer will not object to the employment of Chinese labor, as long as it is confined to mining on the Rand and that by its employment a certain number of the natives may be set free from the mines to help in the agricultural development of the country, especially if the Boer gets his way in education and other matters. In this manner it may become possible to so reduce the cost of living as to permit of the generous employment of unskilled white labor.

With the solution of these great economic problems, no one can doubt that there will be renewed prosperity on the Rand and now that so many proofs have been given of the continued richness of the areas to be developed by the 'deep level' companies, there is every hope for the shareholders in such concerns finally emerging with the same big profits that have accrued to many of the 'outcrop' companies.

EDGAR P. RATHBONE.

London, February 8.

BELTS generally run toward the tight side of the pulley. This is true of vanuer belts, but not of elevator belts, which run toward the loose side.

Deep Mining in the Lake Superior Region.

By F. W. McNair.

*The copper mines of the Lake Superior district are essentially low-grade. Their profitable operation is made possible by the great extent of the lodes, their comparative uniformity of character and the investment of great sums of money to maintain operations on a vast scale over a long period.

With but one important exception, the lodes are the vesicular tops of ancient lava flows that, subsequent to solidification, have had the cavities wholly or partly filled by the deposition of various minerals, among which is native copper. They dip at angles varying from 38 to 70°.

The modern shafts through which the ore is hoisted are either inclined, following the plane of the lode, or are vertical. Several of the inclined shafts are over 5,000 ft. long. One has a length of 8,100 ft. Of the vertical shafts

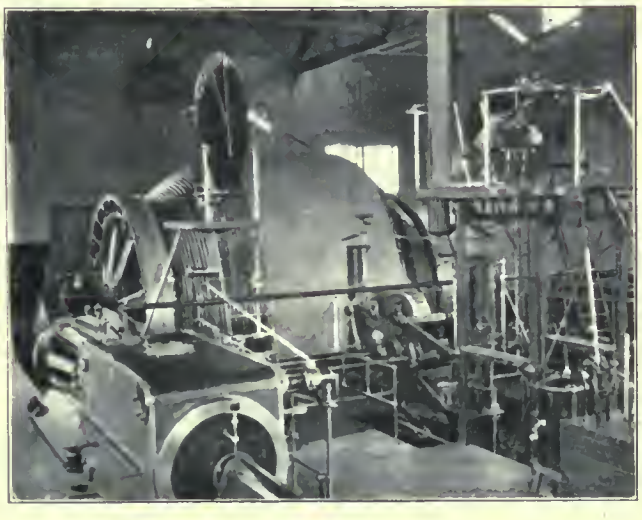
Head-Sheaves at Trimountan No. 4 Shaft.

the three deepest are, respectively, about 5,200, 5,000, and 4,900 ft. deep.

Long before such depths were actually reached there arose the question as to a possible limit set by the ultimate crushing strength of the rock penetrated. Manifestly, mining cannot go to a depth such that the weight on walls of drifts and stopes will exceed the ultimate strength of the material of which they are composed. There is a widespread impression that the Lake mines are approaching such a limit. There are current statements to the effect that pieces of rock occasionally snap off the faces of the workings because of the great strain, and are violently projected as if propelled by an explosive.

In this connection a few figures will be of interest. The average density of the rock of the copper-bearing series is not far from 2.87, that is, a cubic foot weighs about 179.3 lb. Therefore, a horizontal square foot of area at 5,000 ft. from the surface has above it a column of rock weighing 448 tons. The ultimate crushing strength of the average rock is not well known, but since it is mostly trap this may be safely assumed as at least 1,200 tons per sq. ft. If, therefore, the square foot as defined carries the entire column above it, it is loaded to much less than half the crushing strength, and only at nearly three times the assumed depth will the load reach its crushing limit. At a dip of 38°, the pressure normal to the plane of the load at 5,000 ft. from the surface is only 354 tons per sq. ft. It is in this direction that the crushing forces are mostly called into play. As the dip increases this normal pressure of course diminishes. At 52° it is 278 tons, and at 70° it is 152 tons per square foot.

However, the matter does not end here. The removal of large portions of the copper zone leaves considerable areas of the roof or hanging wall to be supported by the pillars that are left for the purpose, or by the walls of the opening, or by both. The weight on pillars and walls is thus increased and may easily approach the crushing limit. Take, for example, a long pillar 50 ft. wide having on either side an open space of 150 ft. Suppose it in a lode dipping 38°. Allowing for neither rigidity nor arching, and supposing the weight on the pillar evenly distributed, at 5,000 ft. deep it would be subjected to a pressure of 1,239 tons per sq. ft., a pressure under which it would fail.



Nordberg Hoist at Trimountain No. 2 Shaft.

As a matter of fact, in such a case the rigidity of the mass distributes a large part of the load out over the rock beyond the walls of the opening. That this rigidity may be considerable is illustrated in several cases where areas of hanging as wide as 200 ft. or more have no support between walls, and yet have stood up for several years. They are not, however, at maximum depth.

In such an area a pillar when first cut out may have to carry but little more than its previous load. As the hanging wall slowly bends the pillar must take up more and more of the extra weight. This is not applied uniformly. As the rock between pillars and walls bends downward the tendency is to concentrate the load at the edge or face of the pillar, or wall, much as a beam does when supported in like manner. The outer parts of the pillar may thus become overloaded and here it will fail. It does so by the splitting off of pieces of rock, much as may sometimes be observed with a specimen in the testing machine, though on a much greater scale. These pieces break from the base as well as the top, and, as a rule, like any hard rock, under a crushing load, the pillar fails suddenly. Small pieces of rock may fly to a considerable distance, and such occurrences have undoubtedly given rise to the exaggerated impression of the compressive stress to which the rock is subjected in the lowest levels.

The hanging rock mass moves, of course, when the pillar crushes, and the vibration due to the sudden though

*Abstract from address before American Association for the Advancement of Science, as published in *Science*. The illustrations have been added.

slight displacement is often conveyed to the surface. The result is a miniature but perfectly genuine earthquake that may be felt over a distance several times that of the pillar from the surface. With the crushing of the pillar and the movement of the hanging, a re-adjustment of the weight takes place, and the process begins over again. Instead of the process being repeated exactly it is possible for the hanging to break in such a manner that the arching effect may protect this pillar, and place the load on others. Eventually, at great depths the hanging and foot must come together, and in one mine the final steps in the process came so rapidly as to completely wreck it.

The pressure normal to the plane of the lode is not the only action that may appear. The pillars are not, as a rule, separate from either foot or hanging. They are parts of the same rock-mass, and it is not possible for the hanging to slide over the pillar. In consequence, the re-adjustments that take place when a pillar fails as above described, sometimes put an enormous longitudinal thrust on the foot, and in places its surface portion has buckled up under such stress. Also, at points where shaft-pillars have been weak, shafts have been pinched and twisted under the same conditions so as to interfere with their operation.

Experience seems to show that at the great depths recently reached it is useless to expect to hold up the hanging rock-mass for a long time by any scheme of pillars unless far too much of the lode is left in place, and that the only feasible method is to cut away the entire lode and permit the hanging to cave as rapidly as it will to the point where the broken rock fills again the whole space, and re-distributes the weight over the foot-wall. Following this plan, stoping begins at a point farthest from the shaft, and progresses toward it. With a wide shaft-pillar, or with the shaft in the foot-wall, and with some such general method that avoids concentration of pressure where it can do harm, there seems no reason to anticipate serious difficulties due to crushing for a further depth at least as great as that already attained.

The difficulties of surveying the mine are not markedly increased by depth, except in the cases of vertical shafts. When these are deep, and it becomes necessary to carry down an azimuth from the surface by means of two plumb-lines hung in the shaft, there is presented a problem of considerable difficulty. It is almost impossible to free the lines entirely from disturbing influences that displace them from their normal positions. If either lines or plumb-bobs are of magnetic material the presence of iron pipes in the shaft may result in seriously disturbing them. Falling water may be in such quantity and so directed as also to affect the position of the lines.

However, the air currents, which cannot be wholly eliminated, whatever the precautions taken, are the most serious cause of disturbance. The temperature at the bottom of the shaft is higher than that at the top, and in consequence convection currents are formed. The heat supplied from the surrounding rock keeps them up. Indeed, with moderately steady temperature at the surface, and with the shaft idle, a remarkably stable condition of these air currents may come about. Elsewhere observations have been published by the writer,[1] showing that their effect on a plumb-line may remain sensibly constant for hours at a time while deflecting the line from its vertical position. The stability of the currents is made possible by the large cross-section of the vertical shafts, 10 by 22 ft. to 10 by 30 ft. outside of timbers, thus giving a large air-body, and the constancy of the rock-temperatures, and the supply of heat through the shaft-walls. When we take account of the fact that a force equivalent to a horizontal pressure of 10 grains on a 60-lb. plumb-bob suspended by a line 4,000 ft. long will displace the bob one-tenth of a foot from its normal position, it is easy to see how apparently slight causes may produce appreciable error in azimuth.

General attention was first attracted to this problem by the noticeable divergence of two long plumb-lines hung in shaft No. 5 of the Tamarack mine. Of course, divergence alone would not affect azimuth, but the question confronting the surveyor is whether the divergence may not be due to some cause that may also displace one or both of the lines in a direction perpendicular to their plane. In the case mentioned it required a great deal of investigation and experiment to fasten the responsibility on the currents of air.

It is remarkable how many persons are ready to accept as an explanation of such divergence the statement that there is an excess of gravitation on each bob horizontally toward the end wall nearest to which it hangs. All are familiar with the picture in the text-books of the plumb-line hanging near the face of a precipice being deflected from the vertical by the attraction of the mountain mass. The idea so strikingly conveyed by this picture, while qualitatively correct, seems in most minds to be quantitatiyely wrong. There is an excess of attraction on the bobs as stated, but its amount is far too insignificant to account for any observed divergence. At Tamarack No. 5 it could account for no more than one one-thousandth of a foot. The convergence of vertical lines in that instance is over three times this amount.

Increased depth tends to lessen the output of a given shaft, and in the effort to prevent this, and also to reduce hoisting charges, loads have grown larger; likewise the speed at which they are hoisted. Loads of nearly seven tons are being raised on some of the inclines at speeds up to 40 miles per hour.

A considerable item in the hoisting charges is the cost of maintenance of the skip-road, the expense per ton for this purpose increasing with the length of the shaft. The usual skip-road is carried on heavy timbers that are placed transversely along the foot, and support large stringers to which the rails are spiked. The expense of maintenance of this road for great depths is such that some of the mines are substituting for it a road consisting of a rail attached to a concrete stringer, which is borne directly on the rock of the foot-wall.

The stringer is about 13½ in. wide by 14 in. high. Beneath it and supporting it is a mass of concrete 16 to 18 in. wide extending to the rock. The depth of this supporting mass depends upon the irregularities of the rock-face to which it is attached. It ranges all the way from 4 in. to 2½ ft., and there is no reason why these limits might not occasionally be exceeded. The stringer and supporting mass are structurally one piece, being molded together. The stringer portion is reinforced by means of a 1¼-in. steel cable passing longitudinally through its interior. The rail is attached by bolts that are spaced three feet apart, and hold it by means of clips which grasp the rail-flange. The bolts pass through the stringer into a rectangular opening about three by four inches in section, which passes quite through the concrete, and affords access to the lower end of the bolt.

In building the road, a form of plank is constructed having the cross-section of the stringer, and a length of 15 ft. To its lower side are nailed the cores for the bolt-openings just mentioned. The top is left open. From one to three of these forms are supported in place underground by suitable means, and to the sides are nailed boards extending downward to the rock. These make the form for the supporting part underneath the stringer proper. When all is firmly secured the rock-face is thoroughly washed, and the concrete is filled in, beginning at the lower end.

[1] See *The Engineering & Mining Journal*, April 26, 1902, also *Electrical World*, April 26, 1902.

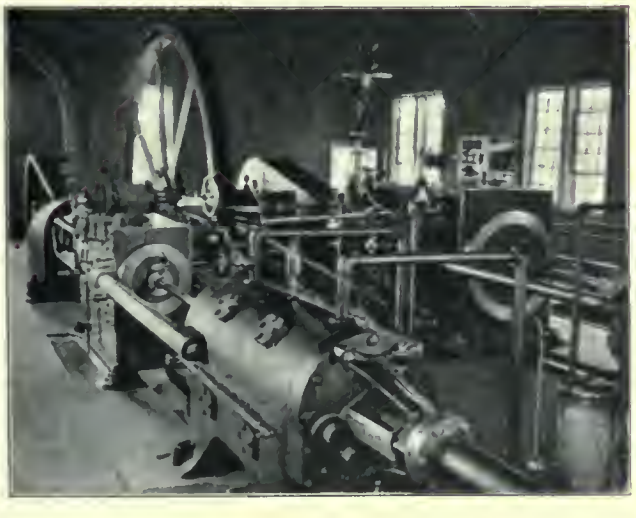
The mixture used is one part portland cement, three of sand, and five of crushed rock, and it is tightly rammed in place. As the filling proceeds the top of the form, or the cover, is completed by nailing on short pieces of plank. In the roads that have beeu built at a slope of 70° the structure is anchored to the foot-wall by heavy bolts spaced 8 ft. apart. When the concrete has hardened sufficiently, the form is removed and the rail is bolted in place. The road is then complete.

The first of these roads has been operating some three

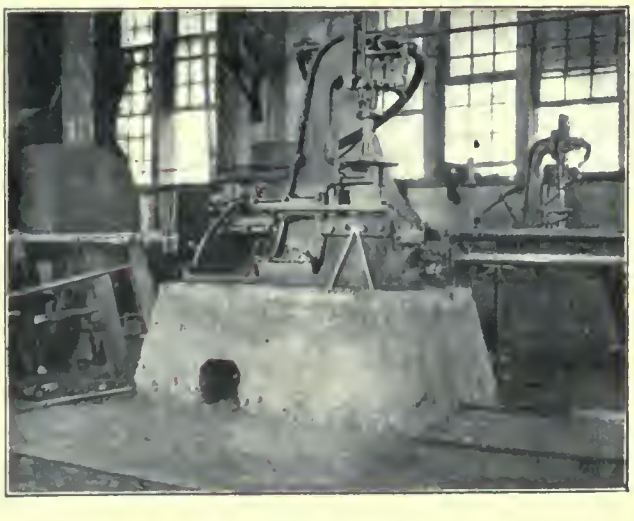
Mass Copper at the Trimountain Mine.

45-lb. Ingots of Copper.

years, and has proved so satisfactory that others have followed. Expectation regarding cost of maintenance has been fully realized, and, in addition, it has been found that the original cost of the road is less than that of wooden construction. Its disadvantages seem to be confined to the fact that, due to the unyielding nature of the



Ingersoll Compressor at Champion B. Shaft.



Word Drill-Sharpener at the Champion Mine.

support, the effect of a blow must be absorbed between wheels and rail, resulting in a perceptibly greater deterioration of both. However, this is far more than compensated by the decreased cost in other directions and the fireproof character of the road.

In the effort to counteract the increased costs due to great depth the economical generation, distribution, and use of power have naturally received large attention. The long period of operation necessary makes it worth while to expend large amounts of money in installing machinery of large capacity and high economy. The extreme in the direction of high-duty engines is represented at present in the Nordberg quadruple-expansion two-stage air compressor operating at the Champion mine. The engine is equipped with Nordberg's regenerative feed-water heating system. It holds the world's record for minimum consumption of heat per foot-pound of work delivered, having shown a duty of 195,000,000 foot-pounds, being about 9% in advance of its nearest competitor.

But one mine is so situated to be able to make use of water-power. The Victoria, situated near the Ontonagon river, has a water-power that has been utilized in a novel manner. Distance from source to points of application is not great and the power for both mine and mill is distributed by compressed air. Moreover, the falling water operates directly on the air without the intervention of water-wheel or other machine.

Roughly speaking, this hydraulic air-compressor consists of a large underground chamber cut from the solid rock and having a length of 281.5 ft., a width of 18 ft. and a depth of 26 ft. In normal operation the lower portion of the chamber is filled with water to a level of 14.5 ft. from its roof. The remainder, having a capacity of over 80,000 cu. ft. is filled with air at 114 lb. gauge. The water outlet is through a tunnel 18 ft. wide and 10 ft. high, the bottom of the tunnel being a continuation of the horizontal floor of the chamber. This tunnel opens into an inclined shaft about 18 by 20 ft. in cross-section, the discharge level of which is 271 ft. above the water-level in the chamber. The outlet for air is a 24-in. pipe leaving the chamber through the roof directly above the tunnel outlet.

The inlet for both water and air is through three verti-

cal shafts, each five feet in interior diameter, opening through the roof of the chamber at the end opposite to the outlets. Each shaft is tightly lined with concrete, and is continued down into the chamber by means of a somewhat flaring steel casing to a distance of about 15 in. below the water-level. Just beneath, and reaching somewhat into the opening of the casing, is a conical boss of concrete. From water-level in the chamber through the air and water-tight shaft to the water-level at the intake above is 343 ft. This is 72 ft. greater than the distance between the water-levels at the outlet end, and this difference expresses the available head of water.

At the intake, water is admitted through an annular funnel over a hollow ring from the flat inner periphery of which project 1,800 tubes of ⅜ in. diam. into the annular opening of the funnel. The water must flow over the mouths of these tubes, and in doing so it produces an aspirating effect, which entrains the air in small bubbles. The air comes mainly through the tubes from the hollow ring, which has suitable intake pipes extending above the water-level. The mixed water and air fall through the vertical shaft, and are discharged radially from the annular outlet formed by the concrete boss and steel casing below. The current through the chamber is slow, and the air disengages itself, collecting in the top of the chamber, and displacing the water. By its pressure on the water surface in the chamber it maintains the 271 ft. of difference in level between that surface and the one at the discharge of the outlet shaft.

While running at less than full capacity the water-level in the chamber is prevented from being depressed further than 14.5 ft. from the roof by means of a blow-off pipe, 12 in. diam., which opens somewhat below the normal water level. When the water has been pushed down sufficiently air enters this pipe, and its escape relieves the excess of pressure. When the blow-off is in operation the appearance at its mouth greatly resembles the eruption of a powerful geyser. The stream of spray, due to the entrance of water with the air from the chamber, is thrown sometimes to a height of 400 feet.

The capacity when all intake shafts are operating is about 5,000 h.p. So far but one intake is used. This under test at near its maximum capacity showed an efficiency of better than 82% while delivering 11,930 cu. ft. of air per min. at 128 lb. absolute pressure.

All machinery at the stamp-mill and at the mine, whether on the surface or underground, is operated by compressed air. Besides utilizing cheap power, the compressor has obvious advantages over the usual machine in the absence of parts to get out of order and in low cost of attendance.[2]

Cost of Dredging.

The following figures, giving the actual cost of dredging operations on two boats at Oroville, speak for themselves. They are worth more than many estimates:

COST OF DREDGING.

No. 1.

Year.	Cu. yd.	Total cost.	Per cu. yd
1903	485,016	$38,583.54	$0.07959
1904	466,262	43,430.32	0.09314
1905	352,826	35,699.32	0.10118
1906	465,207	35,401.30	0.07610
Four years	1,769,311	$153,114.48	0.08654

Using 3½-ft. buckets and in easy digging ground.

No. 2.

1905	589,082	59,115.10	0.10035
1906	557,084	55,454.00	0.09954
Two years	1,146,166	114,569.10	0.09996

Using 5-ft. buckets and in hard digging ground.

Trading on the Curb.

Many persons are of the opinion that trading 'on the curb' is a new proceeding, but this is not so, as it is known that in 1720 a curb market existed in Paris and, as in New York, a part of the street was roped to mark the boundaries of the market. This French market finally became so large that it had to be moved to the garden of a prince, who rented out booths at an enormous figure. The Curb on Broad street was started in the early eighties, when less than a dozen men congregated in front of the Mills building and traded in a few hundred shares of stock daily. The issues bought and sold at that time were principally bank stocks. The Broad Street market pays no rent to the city for the use of the street, and enjoys most of the advantages and escapes some of the disadvantages that are compulsory in a regularly organized stock exchange. Commissions on the Curb are the same as on the big board, namely ⅛ of 1 per cent. The most conservative of the brokers use all possible means to prevent splitting of this regular rate.

The Curb is an open market. It has no admission fees, no restriction as to members, and no listing committees. This has often invited the question: Why is it that a man who wants to buy or sell a block of stock on the market does not do it himself? Can anyone trade in the market? How is the business transacted? These questions are but natural, but let an outsider attempt to save commission by transacting his own business and the question is answered. None but recognized brokers can do business in this market. Signatures of outsiders will not be accepted, and the traders usually put up a job on the newcomer if he attempts to introduce himself.

For many years the Curb has been recognized as a necessary adjunct to the Stock Exchange and its members are jealous of its good name. The Curb absolutely has no organization, by-laws, constitution, or rules for the transacting of business, but there are unwritten laws that are held sacred. The strict observance of these unwritten laws is remarkable when the status of the members is considered.

As in all lines of business, credit is absolutely necessary and credit is given freely without question to the members who prove themselves worthy of it. Very few cases of abuse have been reported. The Curb is a market of the moment where quick action is of prime importance and the short duration of time necessary to transact business is amazing.

When a new issue of stock has been announced in the newspapers or on the ticker, rights to subscribe to the new issues are being traded in on the Curb sometimes within 20 minutes after the announcement. When new companies, formed to absorb two or more old concerns, file papers of incorporation and the news reaches the Curb, the stock of such companies is at once traded in for 'when issued.' This necessitates instant reckoning as to the actual worth of the securities. The brokers seem to solve the problem, figure it out, and start trading in a remarkably short time.

THE 'shell,' or jacket guides, of a rock-drill, when worn, allow the machine too much play, which is likely to break the feed screw and considerably affects the efficiency of the machine, inasmuch as it will waver slightly, each blow of the drill increasing the friction and thus reducing the efficiency.

ASHED DIABASE is a local name used on Keweenaw Point, Lake Superior, for a rock resembling a conglomerate, but which has been interpreted as a very scoriaceous amygdaloidal sheet into which much sand was washed in its early history.

The East Country of the Mother Lode.

Written for the MINING AND SCIENTIFIC PRESS
By JOHN A. REID.

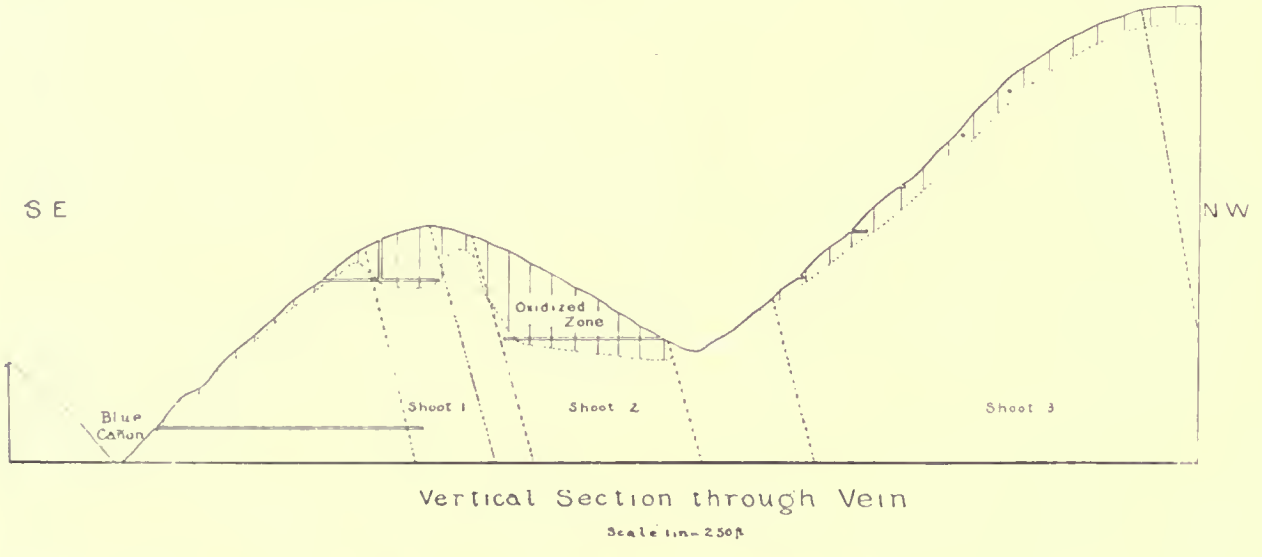
Although gold mining in California has flourished for over half a century, our knowledge of all the mineral resources of the State is still fragmentary. Particularly is this so in regard to that region lying betweeu the middle belt of the Mother Lode and the crest of the Sierra Nevada. Many promising mineral deposits are known to exist in this tract. In this connection the Shady Run miue presents some interesting features.

The Shady Run mine is situated in Placer county, near the railroad, at Midas. This station is four miles west of the village of Blue Cañon, and eight miles east of the mining town of Dutch Flat. The surrounding country marks the upper limit of placer mining, and the old river channel which is cut by the railroad at several polnts near Shady Run, was mined extensively before the anti-debris litigation.

Topographically, the region is a flat-topped divide separating deep cañons. The relief is great and the cañons are so rugged as to be almost impassable. The mining claims reach from Blue Cañon creek, at an elevation of 2,600 ft., to a line near the railroad, at an elevation of 4,000 ft. A difference in elevation of 1,400 ft. is gained in less than three claim-lengths. Timber is plentiful in the cañons and other spots not easily reached, though largely culled on the ridges. Water is also plentiful. The oldest rocks of the immediate locality are all part of the auriferous slate series, of Carboniferous age. At the mine these are fissile dark clay-slates, with a few quartzose beds, striking N. 41° W., and dipping from 80 to 85° NE. A 16-in. lens of limestone, showing traces of crinoid stems, also appears at one spot 100 yards east of the vein. The later rocks comprise volcanic tuffs and flows, and the auriferous gravels.

The great rarity of igneous rocks in the Blue Cañon formation has been noted by Lindgren[1], yet a surprisingly large number of feldspathic dikes occur in the locallty and follow the slates in strike and dip. The dikes are all similar, and chemically almost identical. On physical grounds they may be divided broadly into two types. One of these constitutes a series of about ten thin intrusions from three to twenty inches wide, constituting one large multiple dike. When fresh the color is a light pearl-gray, and the grain exceedingly fine. The color on weathering is first white; on further exposure dark reddish zones of complete oxidation appear, gradually extending inward until the whole becomes a red pulverulent mass. Outcrops are never visible. The second type occurs in one or two larger dikes, from four to twelve feet wide, in part not showing on the surface, and in part outcropping strongly. The fresh rock is of a rather dark-gray color, suggesting a diabase, and the grain medium, with feldspar crystals averaging one-eighth of an inch long. Pyrite is visible in small grains. Toward the periphery of the dikes there is an evident effect on the slates, and the intrusive rock has assumed a schistose appearance — but it is only an appearance.

Under the microscope both types are seen to consist of albite feldspar (ankerite), and a small amount of original pyrite. The albite is in tabular crystals, with frequent Carlsbad twins, as well as the usual albite lamellæ. In the finer grained rock the pyrite is evenly distributed throughout in small grains; in the other rock the pyrite is in larger grains, many of which are secondary. Also, in the partly oxidized coarser rock the tabular feldspars show much black opaque substance between them. This is probably secondary manganese dioxide, from the decomposition of the ankerite, which reacts for manganese.



Vertical Section through Vein

Scale 1in.=250ft

Dikes of this nature have been noted by Turner and others[2], and still present a field for research, bearing both upon the mining geology and the general geology of the Sierra Nevada.

The ore deposits at Shady Run, like the dikes, are divisible into two parts: (1) A quartzose pyritic gold ore; (2) an ore rather low in silica, heavy with arsenopyrite, and containing free gold. These two are distinct, yet grade from one to the other. The first kind is associated with the thin dikes, in seams either parallel to the dikes or cutting in all directions across them. The gold contents are low, but pockets containing coarse free gold occur. A large 'stringer lead' of this character exists about 600 ft. east of the main vein. The second type of deposit is connected genetically with the coarser grained dikes, and consists of a well-defined vein in, or adjoining, the dikes. Small seams of ore and gangue run from the vein into the dike and slates more or less horizontally, the whole carrying, in the ore-shoots, considerable value in gold. The ore-shoots are three in number, as shown in the accompanying sketch. In the largest, the northern, the gold is evenly distributed; in the other two, it occurs irregularly distributed; the more so in the south shoot. This condition is rather common in deposits of arsenopyrite.

There is a distinct zone of oxidation, but no secondary

[1] W. Lindgren, Colfax Folio, U. S. G. S., text.
[2] H. W. Turner. 'Further Contributions to the Geology of the Sierra Nevada.' 17 *An. Rept.* U. S. G. S. Pt. 1, p. 663. C. A. Aaron. 'The Shaw Mine Lode in Eldorado County.' *Eng. & Min. Jour.*, Nov. 19, 1892.

enrichment[3]. The arsenopyrite is readily converted into a soft earthy red limonite, which stains everything a yellowish red. In the more open portions of the shoots the alteration has proceeded downward for nearly 200 feet.

The ore minerals, with the gangue, are interesting and peculiar. The value is in free gold, with some gold held in the pyrite and arsenopyrite. The gangue consists of quartz and albite in about equal amounts, or with a preponderance of the feldspar, and ankerite containing manganese. All these minerals are of the same age, being crystallized one on the other. The gold is coarse, at times as large as grains of rice, and in the oxidized zone it is frequently (and actually) 'rusty.' It is of good grade, worth over $18 per ounce. The arsenopyrite, albite, gold, and pyrite were in part earlier than the others, but the latter stage of their deposition coincided with the earlier stage of the deposition of the main masses of quartz and ankerite. A marked peculiarity of the ore is a deposit of glistening small cubes of pyrite clustered over the surface and sharp edges of the flat rhombohedrons of ankerite. In the numerous vugs in the veinlets through the dike and slates some fine crystals of all the minerals are developed. The clear glassy tabular feldspars are especially fine. The later pyrite occurs, with few exceptions, on the carbonate, showing that the latter mineral possessed some power of precipitating the sulphide from the containing solution. The ankerite is peculiar in its content of manganese, the reaction for which was obtained with the blowpipe. The zone of oxidation is marked by a large amount of secondary wad, the earthy oxide of manganese, which gives a hint concerning the nature of the black opaque substance shown by the microscope in the dike rock. The source of the ore is connected with the dike itself, as the gangue minerals are the same. The solutions were evidently rich in alkaline carbonates, and probably represented the last stages of consolidation of the acid magma below. Further, the rather large amount of hydrothermal action between the intrusive rock and the slates indicates a pneumatolytic character, in part at least, of the dike.

There are a number of other mining properties near Shady Run. The only one now producing is the Rawhide, situated about two miles south on the north fork of the American river. Ten stamps are dropping. The ore is a gold-bearing quartz, said to be rich. A large quartz vein outcrops to the east of Shady Run, from Blue Cañon to the railroad. It strikes north and south, and the greatest width exposed is over 50 ft. Nothing is yet known of its value. This whole belt of country is well mineralized, and needs much more intelligent examination. And this is true of all the larger area of the so-called 'east country.'

DURING the past seven years, from 1900 to 1906 inclusive—the fiscal year ending June 30—the Homestake has disbursed for mine labor $10,253,532.78, and for dividends, $7,648,600. During the fiscal year of 1906, it paid in dividends $1,310,400 and for labor $1,665,798.22—about 32% of the gross yield of the mine for the year.

IN the degree that 'organized common sense' or science has been a factor in the lives of men and nations, men and nations have been happy and effective. The ultimate function of science is the regulation of human conduct.

---

[3]This fact supports strongly the recent experiments of Stokes upon the solubility of gold in ferric sulphate. In spite of the large amount of this reagent that has been formed by the oxidation of the ore, no perceptible transposition of the gold has occurred. See *Economic Geology*, Vol. I, No. 7, p. 650.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

While in some instances courts have questioned the necessity of an actual discovery of mineral upon gold placer ground, it is now the established rule that appropriate discovery is as necessary to the location of a placer claim as to the location of a lode claim.

Steele *v* Tanana Mines R. Co., 148 Fed. 678.

A showing of colors of gold in each instance of panning, and the fact that many of the pans gave what miners call "good prospects" of gold, was held insufficient to justify a person of ordinary prudence in further expending labor and means with a reasonable prospect of success. Such prospects were insufficient to show that the land was so valuable for mineral as to take it out of the category of agricultural lands, and to establish its character as mineral land, in a contest between a mineral claimant and another claiming the lands under other laws of the United States.

Steele *v.* Tanana Mines R. Co., 148 Fed. 678.

When the controversy is between two mineral claimants, the rule respecting the sufficiency of a discovery of mineral is more liberal than when it is between a mineral claimant and one seeking to make an agricultural or other entry under the land laws. The reason for this distinction is said to be that, when land is sought to be taken out of the category of agricultural lands, the evidence of its mineral character should be reasonably clear, while in respect to a controversy between rival claimants to mineral land, the question is simply which is entitled to priority.

Steele *v.* Tanana Mines R. Co., 148 Fed. 678.

The owners of three-fourths of a certain mining claim gave another person permission to enter into possession of the claim and make the location of another claim; thereafter the owner of the remaining one-fourth executed a ratification of the abandonment of the first named claim; under such facts, it was held that subsequent locators could not complain that the initiation of the second claim was by trespass, and that the ratification did not validate it.

Oberto *v.* Smith, (Colo.) 86 Pac. 86.

In an action to recover possession of unsurveyed Government mineral lands, where prior possession was the sole question involved, the court ruled that it was not necessary for the plaintiffs to allege that they had the necessary qualifications, such as being of lawful age, etc., to enter Government lands nor to state a good cause of action and entitle them to recover.

Davis *v.* Dennis, (Wash.) 85 Pac. 1079.

Where a person was induced to purchase mining stock by fraudulent representations, it was decided that he was not prevented from rescinding the sale on account of such fraud, because the stock had decreased in value.

Barron *v.* Myers, (Mich.), 109 N. W. 862.

A mining claim may be said to be abandoned when the locator leaves it without any intention of returning, and without regard as to what becomes of the claim or who may appropriate it. But the mere leaving of a claim with intent to return later is an abandonment.

Davis *v.* Dennis, (Wash.) 85 Pac, 1,079.

A lease giving the lessee for a term of years the right to mine and operate for oil and gas, does not constitute a sale of the oil and gas in place, and the lessee has no vested estate therein until gas or oil is discovered; but under such a lease it was held that when such oil or gas was found, the right to produce became a vested right, and when gas or oil was extracted, the title vested in the lessee, and the consideration or royalty paid for the privilege of search and production was rent for the leased premises.

Headley *v.* Hoppengarner (W. Va.) 55 S. E. 744.

The Old Camp of Ward, Nevada.

Written for the MINING AND SCIENTIFIC PRESS
By H. R. PLATE.

Ward, in White Pine county, Nevada, has been deserted for the past 25 years, but owing to the development of the great copper deposits of Ely, it now exhibits signs of life.

The Martin White mine, which supported the town of Ward, was one of the large producers of Nevada during the '70s and early '80s, and is credited with a production of several millions of dollars in silver and lead. A brief description of its situation and a little of its history will be interesting and give one a better idea of the adverse conditions under which the mine flourished in those days.

The mine lies on the west slope of the Steptoe valley, in the Egan range, about 16 miles south of Ely. In the early days the nearest railroad point was Palisades, on the Southern Pacific, a distance of about 200 miles; machinery and supplies were hauled by teams from this point and the ore and bullion were hauled out in the same manner to be shipped to San Francisco. Under this handicap and a still greater one, of poor milling and treatment methods, which I will describe later, the mine prospered and declared dividends until it finally shut down when silver depreciated. From company letters and books found in the mine-office and bearing the dates of the '70s, the cost of mining and milling was approximately $50 per ton, consequently ore running below that figure was left in the mine. The tailing from the mill ran about $16 to $20 per ton. The mine was not intelligently developed or prospected; a system of 'gouging' the richer ore, with no thought of tomorrow, was carried on. I am told that many thousands of dollars of rich ore and even bullion was stolen from the company.

With the above as a brief introduction to the conditions that existed in those early days, one can better understand the simpler problem that the operators of today have to contend with.

The geological formation of the district is limestone, stratified and slightly tilted from the horizontal; through the lime are numerous intrusions of porphyry. These dikes vary slightly in direction and thickness, but generally have a northwest and southeast strike and a dip to the southwest. The orebodies occur in a filling between the lime and the porphyry, and the mineralized solutions have penetrated the softer rock (porphyry) and deposited the sulphides for some distance from the contact. The ore varies in width from a few feet to nearly a hundred feet. The deposit, as a whole, resembles those of Red Mountain, near Ouray, in Colorado.

At, and near, the surface the ore was rich in silver, containing also lead and small amounts of gold and copper; as depth was gained the copper increased and the silver decreased; I am told that, in places, rich gold ore was found associated with wire silver and silver nuggets, some of the ore being almost solid metal. The length and depth of the orebodies were never actually established, I believe, for, as I have said before, the system of 'gouging' near the surface (150 to 200 ft.) predominated and systematic development was neglected.

The character of the ore, as shown at different points on the surface, varies greatly; at one point it will be entirely copper carbonate, and a few hundred feet away galena and lead carbonate; none of the rich silver or gold ore remains on the surface or dumps; lessees have removed it.

During the life of the mine, a lead smelter, of possibly 100 tons capacity, was built and operated for a short period; this was an unsatisfactory treatment, owing to the increasing percentage of copper. Next a lixiviation plant was erected, tried, and abandoned; finally a 20-stamp mill was built and run irregularly until the mine was shut down (about 1883). The method of treatment, in this mill, was as follows: The ore was crushed and dried upon an open iron floor, then roasted in a revolving tubular furnace; from the roasters the ore was elevated to the stamps and crushed to 40 mesh and run to the pans to be amalgamated; the product from the pans went to the creek. From a study of the ore, which contained galena, copper sulphides, and carbonates, one can readily see why the tailing assayed so high. To do justice to the operators of those days, however, such a mill was practically the only type on the market and it was a question of making the ore suit the mill, if possible; today we have a wide choice and can design a mill or smelter to suit the ore.

As development progresses and the orebodies are opened to a greater depth, the ore is likely to become a copper sulphide with some gold and silver; in that case it will be a typical concentrating proposition and little trouble will be experienced in making a good saving.

The old workings consist of several adit levels, numerous shafts and open-cuts. All the adits and shafts are badly caved and little can be seen of the underground workings, but the dumps give mute evidence of what was encountered during the old days. Most of these dumps are covered with copper ore that had been sorted and thrown out to assist the treatment in the smelter and mill; the copper seemed to be the sole source of the trouble, and it was kept out of the ore in every possible way. The dumps from the mine, smelter, and mill have been sorted over and worked by lessees, who have made money from them, but there still remains a good profit for the company when it is ready to treat them with the proper methods of mechanical concentration. The product can, today, be shipped by rail to the custom smelters at Salt Lake, and be treated for a nominal figure, or later it can be treated at Ely, when the Nevada Consolidated Copper Co.'s smelter is completed.

The greatly improved methods of ore reduction, together with cheaper transportation, and the high price of lead and copper, will make it possible for companies to open and successfully operate properties of this type, which have lain idle for many years. Nevada has many such idle mines as the Martin White, and I shall not be surprised to hear that many of them will be re-opened and prove themselves far from worked out.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

Specimen from Cedarville, Cal., marked F. A. E., is Quartz with galena.

Those from Orleans, Cal., marked C. S. L., are: No. 1, chloritic schist, with crystals of Pyrite; No. 2, altered Diabase; No. 3, brown Jasper.

The specimens from H. M. R. of Tonopah, Nev., are: No. 1, scaly talcose rock; No. 2, Mica-schist with pyrite; No. 3, Quartzite with Pyrite and stained with iron and manganese oxides; No. 4, Volcanic Breccia; No. 5, tufaceous Sandstone; No. 6, Chert; No. 7, vesicular Lava; No. 8, highly altered rock containing manganese oxide and limonite; No. 9, Basalt; No. 10, Pegmatite; No. 11, green Jasper; No. 12, Quartz containing Rhodonite; No. 13, missing; No. 14, Rhyolite; No. 15, serpentinized rock with dendritic manganese oxide; No. 16, Clay, stained by manganese; No. 17, altered Pegmatite; xy, altered Mica-schist.

A Slag-Casting Machine.

Written for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

Mr. B. N. Bennetts, superintendent of the Garfield smelting plant of the American Securities Co., while in charge of the blast-furnaces of the Tacoma Smelting Co., at Tacoma, Wash., installed and put into successful operation the slag-casting machine shown in the accompanying illustrations. Fig. 1 gives, in plan and section, the general arrangement of the machine, the hoist, and the position of the furnace and fore-hearth supplying it. Fig. 2, 3, and 4 give the details of the automatic dumping device for the discharge of the matte or slag from the molds.

The machine consists of a continuous bed of molds resting on two 3 by 5 in. angle-iron rings, as shown in cross-section in Fig. 4, these rings being supported at every four feet by a pair of wheels and axle rolling on a circular track of 3.6 ft. gauge and 62.5 ft. diam., centre to centre of the tracks, the molds moving in the direction shown by the arrows in Fig. 1. The molds are furnished with trunnions revolving in bearings attached to the angle-iron rings, so that they can be reversed in order to discharge their contents into hoppers set below them as shown in section. As the plan in Fig. 3 indicates, the inner trunnion

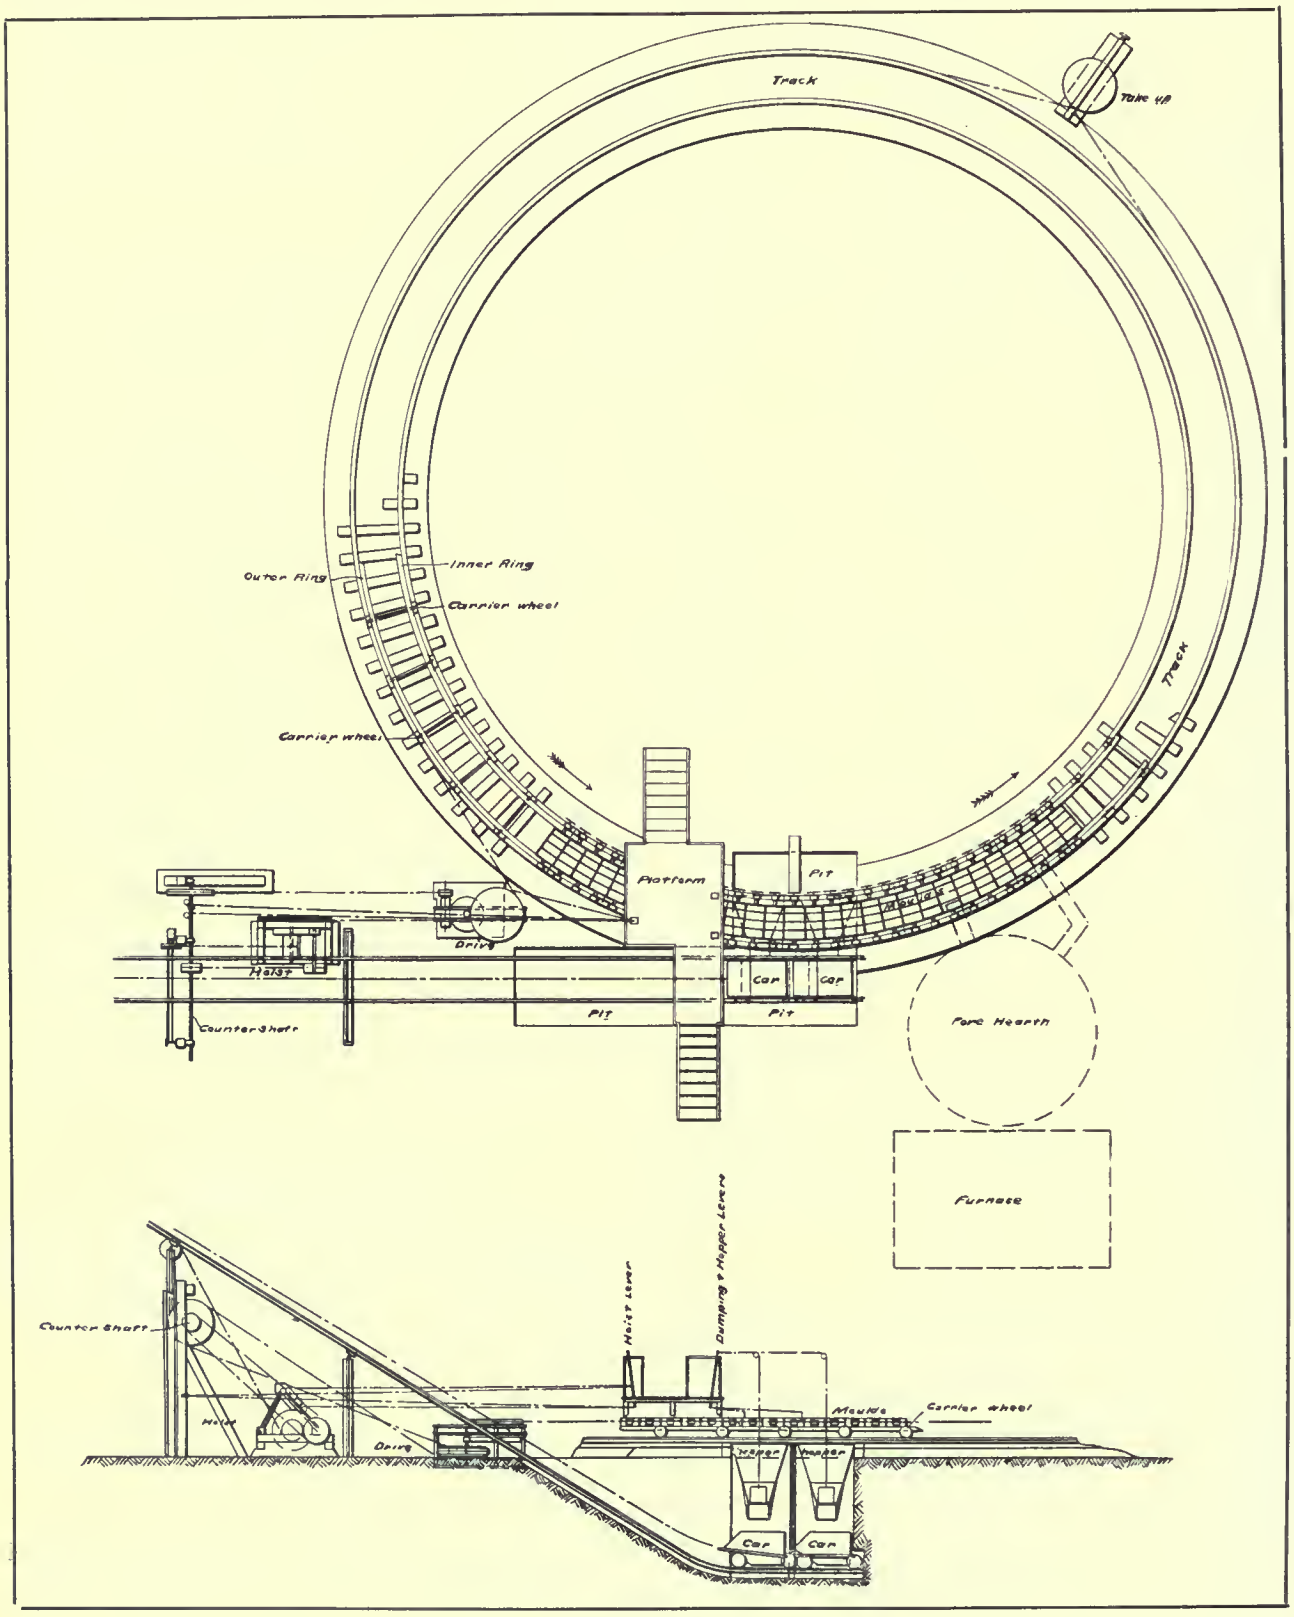


Fig. 1. Plan and Section of Slag-Casting Machine.

carries a cross-arm having two pins, one (*m*) larger than the other, the other view of the cross-arm being as shown in *g* in Fig. 2. Above the hoppers on the inner side of the track is the tripping device by which the molds can be tipped over and emptied at the will of the operator, who stands on a platform at this point. The device consists of a frame carrying guides into which the larger pin of the cross-arm engages. The molds overlap so that the

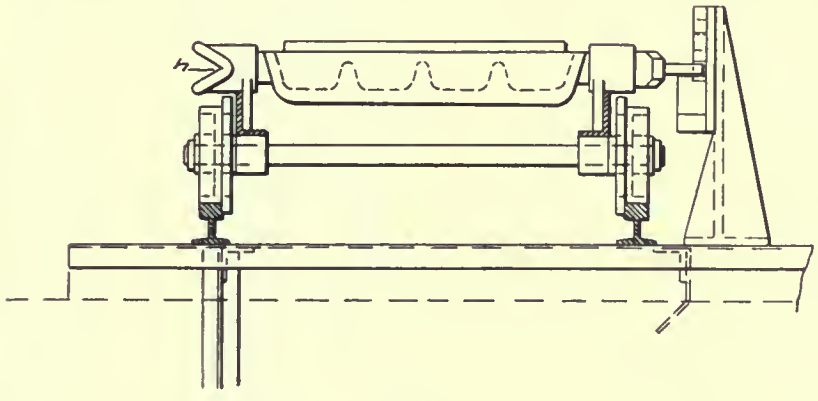

Fig. 4.

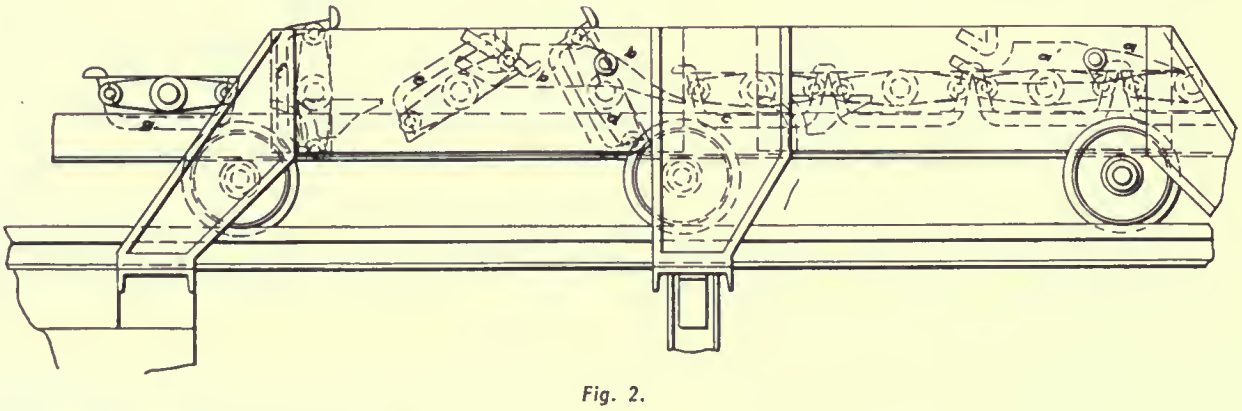

Fig. 2.

joint between them is covered and the machine being put in motion, the molds are filled as they continue to revolve. When the filled molds come around to the hoppers, the operator raises the latch *b* in Fig. 2, for example, and the pin *m* guides through the grooves of the frame inverting the mold when it assumes the position *e*. Moving on the other pin *k*, the mold encounters a guide-block which restores it to its original position ready for again filling. For the other hopper there is a latch *a*, so that either hopper can be filled at will. The operator can, by operating a lever, also open the hopper-slide when he wishes to load a car. The molds are filled from the fore-hearth set high enough to discharge both slag and matte to the molds. When matte is cast, a hopper is reserved for it. The mold ring is revolved by means of an endless-rope drive, and the rope is kept tight by means of a take-up on the side opposite to the drive.

Both matte and slag are hoisted by the cars shown in Fig. 1 to receiving or storage bins (not shown) whence the material may be drawn off, the slag being sent to the dump while the matte is re-crushed for roasting. There are 144 molds, each capable of holding 144 lb. of slag, and the mold-ring makes one revolution in 40 seconds, or 10 tons in that time. The operation of the machine is intermittent, the operator stopping when molding is not needed. Each of the blocks of one mold weighs 36 lb., when the mold is completely filled, but evidently when thinner blocks—as of matte—are needed, they can be just as readily cast. There is no need of cooling by water under ordinary circumstances of furnace running, and the inconveniences of water cooling are thus avoided, but for large capacity it is obvious that this, as well as a mold wash, could be added. The molds are given the clay wash by hand. Five or six horsepower is enough to operate both machine and hoist, and one man can operater it. It is intended to put in a similar machine at Garfield.

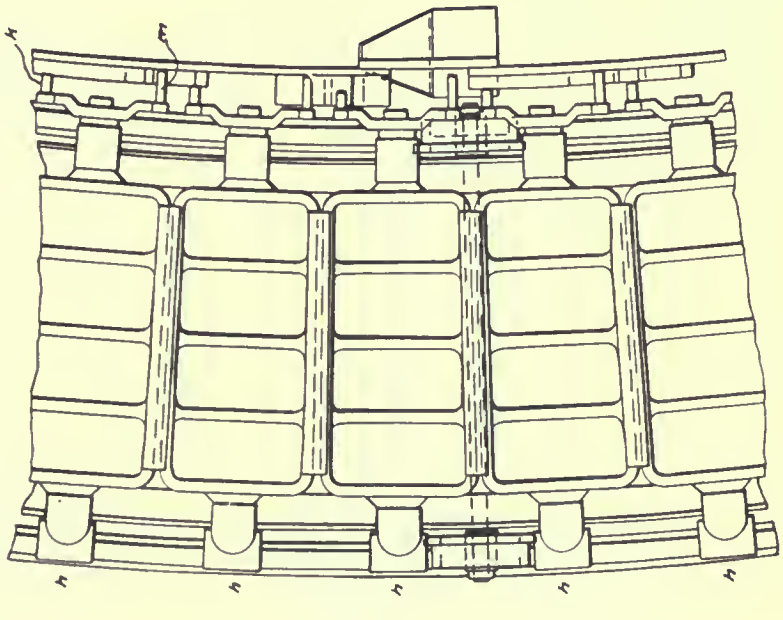

Fig. 3.

In the operation of air-compressors the best results are obtained when the areas of the suction and discharge valves are equal and of such proportions that the velocity of the air does not exceed 5,500 ft. per minute. On a compressor run with a piston speed of 550 ft. per min., this requires a valve area equal to 10 per cent of the piston area. The practice of making suction-valve areas larger than those of the discharge valves is not advised as, while the incoming air is of greater volume, the discharge valves remain open for a very small proportion of the stroke.

For transmission of power in mines where compressed air is used, it has been found that, for general purposes, a moderate pressure of 6½ to 7 atmospheres is the best practice.

A Miner's Drills and His Work With Them.

Written for the MINING AND SCIENTIFIC PRESS
By MATT. W. ALDERSON.

I was somewhat surprised, not long ago, to read in a prominent mining journal that a set of miner's drills ranged in length from 8 to 24 inches. I was taking my regular physical culture exercises at the time and I said to myself: "That cross-cut you are driving wouldn't go in very fast if you had no steel longer than 24 in. and the contractors working for you at the tunnel would throw up their job if they were limited to such lengths."

Out of curiosity I kept a record of the holes I drilled the next day. One was 13, one 25, and one 31 inches. The first was a relief hole, the others were down holes in the face of a cross-cut. The next morning I put in a breast hole as high up as I could without spoiling it as a water hole, and it went in 36 inches. With a set of drills, the longest of which was 24 in., one can put in a hole as deep as 20 in., but the average hole made with drills of such a length will be about 18 in. I know I could not have done the work accomplished by the 36-in. hole above mentioned with less than three 18-in. holes and the chances are it would have taken four. I often feel when I get a hole in as far as a 24-in. drill will make it: "That's a good collar; now make a place for the powder."

The most expensive part of mine work is drilling and a good workman learns to put in deep holes. He may put in a number of short holes to get a chance for a good long one, and if at all skilled, he shapes his ground to that end. Occasionally this is done by carrying in the bottom, then reaching out with long down holes and long breast holes. Sometimes one will carry in the centre and then by well placed down holes and an upper, each of which would be over two feet in length, make things count for good. Sometimes in driving along a seam, there is a gouge or soft place on one wall; and a man will put in a day or even longer clearing this out so that he may put in long holes and break to this crack.

If I had a workman satisfied with a set of drills, the longest of which was but 24 in., I would feel that it was not possible for him to do as good work as he could with longer steel, and I would encourage him to reach out after more ground. I have had men work for me who always placed their holes so that they broke perfectly. I would rather have one who occasionally failed to get all he expected. He will accomplish far more in the long run. Objection to long holes is made by some because they cannot always be made to break to the bottom. In loading holes I never load a long hole with dynamite for half its length. Suppose that in drilling I have crossed a slip; the hole may break to this slip only, and leave the bottom part unbroken. It is easy to load it again, with three half-sticks of dynamite, and, all told, I have not used more explosives than some persous would use at the first charge, and I get results—something one seldom gets by loading a hole nearly a full length. Suppose a man has been driving in ground which has broken well and he has reason to think from the way the hole has drilled that the ground may not break as perfectly as he first thought. Ground changes in character sometimes in a very short distance. The wise workman does not run the risk of spoiling the hole that it has cost so much to make. He loads light, to chamber the bottom of the hole. He then re-loads with such powder as can be placed in the bottom of the hole, where it will do good execution, and makes things come as he wishes. Any fool workman can blow the collar off a hole and spoil the rest of it. All he has to do is to use powder for tamping, as too many do, and then curse his luck. It is the bottom of a hole where the explosive is needed. I never knew a man whose hole broke at the bottom who had to re-load the collar.

I have written thus far concerning development work. There are veins, of course, where it is advisable to drill short holes only. One must use intelligence and adapt the work to conditions. Eight to ten years ago, at a mine three miles from where I am working, sets of drills were used, the longest of which was seven feet in length. This was in breaking orebodies 6 to 14 ft. wide. It was a usual thing to put in holes by hand six feet in depth, charge with three or four sticks of powder, fire, load again with 5 to 10 lb. of explosive (half a box, the men would say) and fire again. It stood one in hand to be out from under when one of these charges went off. The ground was broken on such a scale that it was often necessary to put in numbers of pop shots to break up masses that were blasted down. Work with drills 24 in. long would be child's play in comparison to this.

If I were making a set of drills from new steel, for the ordinary work in a mine, I would make the shortest cut 12 inches. It will wear down and make a shorter starter in time, short enough so that eventually it will be made into a gad or a moil. I would make each additional drill four inches longer until I had a set with the longest drill 44 in. There should be twice as many drills up to 30 in. as beyond, because most holes will be under two feet, but I would outfit a man for deep holes and encourage him to get them in wherever possible.

A word as to the shape of the bit. Bits are made either crowning or chisel-pointed. The crowning bit is crescent shaped on a profile view, the chisel-pointed straight across. For years I believed that the crowning bit was the only bit for hard ground, but experience has taught me the contrary. The chisel-pointed bit can be made to stand as well as the other and as a cutting bit it is far superior.

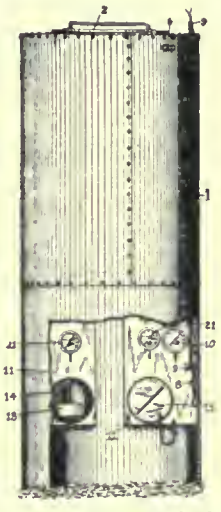
ALUMINUM.—It is of interest to remember that, nearly a hundred years ago, Davey dissolved alumina, but failed to isolate the metal, although he named it. It was not until the year 1855 that the French chemist, Deville, showed that aluminum could be prepared on a large scale and in a compact form without very much difficulty. Although the mineral cryolite, which is found in Greenland and is a double fluoride of aluminum and sodium, was the one first used for the manufacture of aluminum, nowadays bauxite is used for the purpose. Bauxite is a clay consisting chiefly of alumina or oxide of aluminum, and oxide of iron. Electrolytic methods are employed in the preparation of the metal, and full advantage is taken of the hydraulic power at Neuhausen, and, on a larger scale, at Niagara, to obtain the current necessary. Aluminum is very malleable and ductile, and in tenacity it approaches iron. It fuses at about 700° C., and does not oxidize. It has been known for some time that aluminum forms suitable alloys with copper, although the above-mentioned reports place the properties of all these alloys on record for the first time. Aluminum appears to alloy with tin, and has been used for optical instruments, and it is therefore possible that further research will be done on aluminum and copper alloyed with tin.

ASBESTOS.—Recent prospecting in the northwest part of India has disclosed a number of veins of asbestos, samples of which have been sent to the consulate-general with inquiries as to the demand for asbestos in the United States. The veins are reported to be four feet broad and just how deep has not yet been ascertained, but it is believed by experts that the deposits are extensive. The quality seems to be good, and those directly interested are quite sanguine of being able to make shipments in considerable quantities within a short time.

MINING AND METALLURGICAL PATENTS.

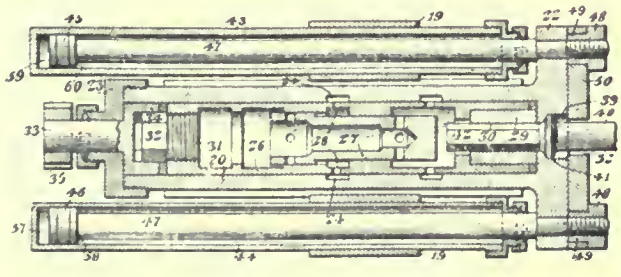
Specially reported for the MINING AND SCIENTIFIC PRESS.

DEVICE FOR PROSPECTING AND MINING FOR GOLD.—No. 843,606; Robert Hornbeck, George B. Campbell, and Basil F. Hite, Sacramento, Cal.; said Campbell assignor to said Hornbeck.



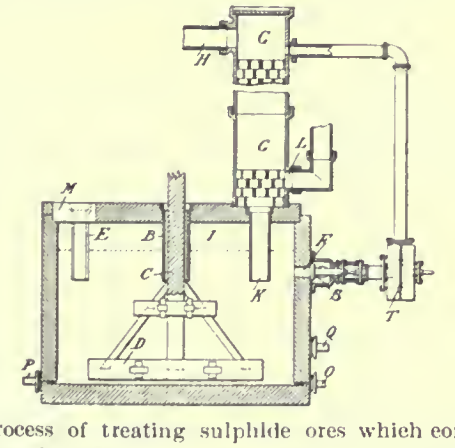
In a device of the character described, a main bottomless tube, an air-tight cap on the upper end of said tube, a plurality of smaller tubes arranged within said main tube and suspended from the top thereof, said smaller tubes being closed at both ends and having openings near their lower ends, air-tight covers for said openings, said main tube and smaller tube adapted to be filled with compressed air, and hoisting means arranged within the smaller tubes, substantially as described.

ROCK-DRILL FEEDING MECHANISM.—No. 843,718; Thomas Turner, Ottumwa, Iowa.



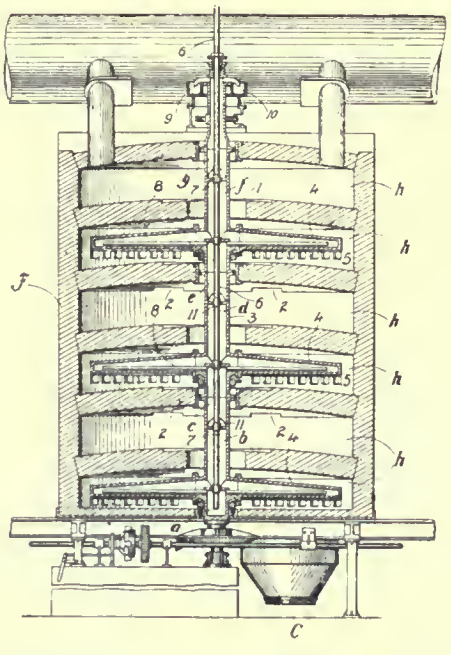
In mechanism of the class described, the combination with a motor, of a plurality of fluid-actuated feeding devices for moving the motor, and means for admitting motive fluid to one or more of the feeding devices to vary the pressure thereof upon the motor.

PROCESS FOR THE TREATMENT OF SULPHIDE ORES.—No. 843,986; Harry Baker, and Andrew T. Smith, Weston Point, England.



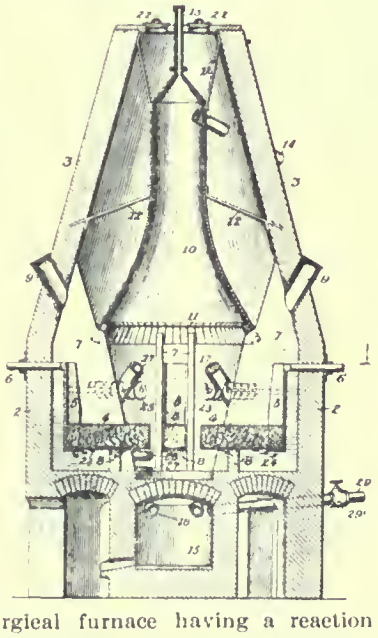
The process of treating sulphide ores which consists in submitting the ores to the action of chlorine, in the presence of water and a metal capable of forming both higher and lower chlorides, in such a manner as to form the higher chloride, which immediately reacts on the ore to form chlorides of the metals contained therein, and is itself reduced to the lower chloride, treating the solution in such a manner as to reconvert the lower chloride into the higher chloride without permitting free chlorine to come into contact with any sulphur which may have separated, again submitting the ore to the action of the regenerated solution, and so on continuously until the desired metals are fully extracted from the ore.

ROASTING-FURNACE.—No. 843,825; Frank Klepetko, New York, New York.



In a furnace having a plurality of hearths, a rotatable hollow shaft passing through the hearths, a series of hollow arms radiating from said shaft and extending into the several hearths, a series of chambers distributed throughout the shaft and communicating with the hollow arms, a feed-pipe communicating with one of the terminal chambers of the series for conveying a cooling medium thereinto, and a water-feed pipe extending through the several chambers and discharging its water into the same.

ELECTRIC FURNACE.—No. 843,776; Edward R. Taylor, Penn Yan, New York.

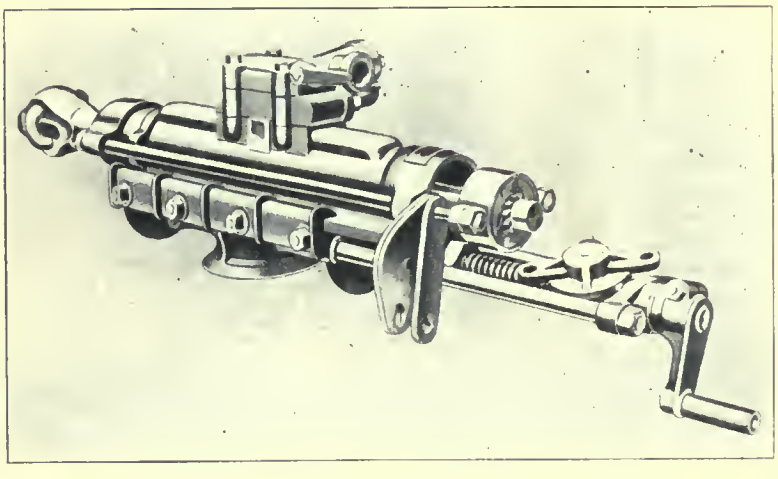


A metallurgical furnace having a reaction zone, and means for feeding portions of the charge through a surrounding body of the charge to said chamber, and means for feeding a suitable charge downwardly in proximity to the periphery of the furnace, and then feeding portions of said charge inwardly through a surrounding body of the charge to said chamber, and a collecting-chamber below said reaction-chamber, and intermediate conduits, said conduits arranged to traverse the incoming charge.

The Chicago Giant Rock-Drill.

The designing of a successful machine-drill calls for an intimate knowledge of the conditions and ruggedness of service in which it has to operate and perform successful work. As it stands today the machine-drill represents an evolution of improvement, made necessary by a long line of demonstrations and failures in actual service. In the design and development of the machine shown in the accompanying illustration (the Chicago Giant Rock Drill), full advantage has been taken of the opportunities presented by embodying such features as have proved their fitness in successful service, combining them with improving features.

Every detail has been given careful consideration as to its desirability; suitability of material and weight. One of the improved features is the shell, which is of the adjustable type, constructed so as to provide for double side bearing for the cylinder; and the shell caps are so made that they will 'take up' wear in two directions (horizontal and vertical) with one adjustment. A removal cylinder stop is also



The Chicago Giant Rock-Drill.

provided in the lower end of the shell. Its function is to prevent the cylinder from slipping out of the shell in case the feed-screw should be run out of the feed-nut. On the other hand, should it be desired to remove the cylinder from the shell, all that is necessary is to first remove the stop, then by turning the feed-screw run the cylinder down in the shell until the feed-screw is out of the feed-nut; this will allow the cylinder to be slipped out of the shell without any dismantling of the machine.

The cylinder is cast from a special mixture, having a tensile strength of 35,000 to 38,000 lb., and presenting a fine polished surface when finished. The upper end of the cylinder is extended to form a chamber for the rotating mechanism, which is of the releasing type. Three parts are used, thus equally distributing the rotating effort, and the pawls are constructed so that they are reversible; that is, should one of the engaging edges wear out, the pawl can be reversed so as to present the other and unworn edge to engage with the ratchet. This is an important point, as it makes provision for doubling the life of each pawl. The ratchet is of one piece, with the rotating or rifle-bar, which is extended on its upper end to fit into a chamber or recess into the upper head, this provides for the holding of the rotating bar in a central position, and relieves the rotating mechanism of all side strains. The valve motion is positive and is of the tappet or rocker type, modified to give a short stroke feature, the length of the stroke being at all times completely under the control of the operator. The supporting pin of the rocker works in removable steel bushings, and is completely enclosed, it being kept in place by caps easily removable, but which are securely locked in place by the valve-seat when machine is assembled.

One of the most valuable features of this drill lies in the provision for automatic lubrication. An oil reservoir chamber is provided in the valve-seat, and communication is made between the oil-reservoir and the interior of the valve-chest. The oil is led through this channel into the chest, where it mixes with the operating fluid and is carried by it into the interior of the machine. One filling of the oil-reservoir will last half a shift. In case the rotating mechanism should not receive sufficient lubrication from the interior, provision is made in the upper head whereby it may be oiled when necessary. In the make-up of the machine only the best and fitted materials are used. The workmanship is of the best, and absolute interchangeability of parts is assured. The machine is manufactured by the Chicago Pneumatic Tool Company.

Commercial Paragraphs.

THE AMERICAN SPIRAL PIPE WORKS of Chicago, through their Denver office, recently sold to the Peninsular Hydraulic Mining Co., of Nome, Alaska, a large amount of 26, 24, and 22 in. pipe for use on their placer property.

THE GOLDEN WEST PLATING WORKS, of San Francisco, have moved to larger quarters at 353–361 First St., where they have excellent facilities for manufacturing amalgamating plates of the highest grade.

THE J. GEO. LEYNER ENGINEERING WORKS CO., of Littleton, Colo., recently made a shipment of 23 electric hoists to Goldfield, Nevada. The smallest was 20 h.p. and the largest 80 h.p. On account of congestion of freight between Denver and Goldfield, one of the cars was shipped by special train in order to insure prompt delivery of machinery. They also recently shipped to the Kansas City Southern Railroad Co., for their shops at Pittsburg, one 1,600-ft. air-compressor; this order was placed by Arnold & Co. of Chicago; also one 400 cu. ft. and one 300 cu. ft. air-compressor with boiler equipment to the Governor of Sonora, in Mexico; this last is to be used for pumping water for irrigation purposes; two steam-hoisting plants to the Cananea-Bisbee Development Co., at Naco, Arizona; one 25-h.p. electric hoist to La Providencia Mining Co., Guanajuato, Mexico; and during the month of January seven compressors were shipped to Japan with full complement of water-Leyner and Leyner air-drills.

Publications Received.

'Summary of the Mineral Production of the United States in 1905.' U. S. Geological Survey, Washington.

'The Progress of the Mineral Industry of Tasmania,' for the quarter ending September 30, 1906. Compiled by W. H. Twelvetrees, Government Geologist.

PRODUCTION OF GAS, COKE, TAR, AND AMMONIA, at gas works and in retort coke ovens, in 1905. By Edward W. Parker, U. S. Geological Survey.

ILLINOIS GEOLOGICAL SURVEY. Administrative report for 1906, by H. Foster Bain. This is a good example of the work done by an efficient State Survey.

'The Decomposition of the Feldspars,' by A. S. Cushman and Prevost Hubbard. U. S. Department of Agriculture. Office of Public Roads. An interesting paper, of practical use.

Trade Treatises.

United Iron Works of Oakland, Cal., sends Folder 28, descriptive of their Eclipse centrifugal pumps. Besides general illustrations of step-pressure pumps, it presents a novel elastic system of mine drainage, also methods for elevating mill tailing and for dredging with sand and gravel pumps. It will be sent to interested parties upon application.

Editorial.

THE American Association for the Advancement of Science meets at Chicago this year and the Geological Society of America will meet at Albuquerque. Both meetings will afford an opportunity for the contact of ideas from the East and the West.

AT LONDON, in the boom days of the past, they called the South African department of the Exchange, the Kaffir circus. At Boston there is a notoriety-hunting spoofer named Thomas W. Lawson. The London circus will be incomplete until it secures the services of the Boston clown. He has made advertising an absurdity, and finance a folly.

THE annual report of the Portland Gold Mining Company, just to hand, gives the names of the subordinate officers at the mine and mill, as well as those of the president and directors. This is eminently fair and proper. A faithful shift-boss is often of greater value in the operation of a mine than a figure-head director. A good executive at the head and an efficient staff are equally necessary, and it is an important part of the duties of such a chief to see that he has trustworthy subordinates.

THE APPEAL for $7,500,000 needed for the University of Cambridge has drawn attention to the indifference of wealthy Englishmen to the financial necessities of the universities of their country as compared to the lavish generosity of American plutocrats. Similarly, the fact that the British Empire, which controls the larger part of the mining industry of the world, has no properly endowed school of mines is another feature that is hard to reconcile with the genuine philanthropy and public spirit of the best kind of Britisher. One would think that they would do something handsome for a historic institution like the Royal School of Mines.

ACCORDING TO certain authorities, America is suffering from an excess of prosperity and in evidence of it they point to the scarcity of labor and fuel, the breakdown in railroad transport, and the lack of money for construction, culminating in a shrinkage of values on Wall Street. Even a restricted currency is blamed. Meanwhile it will be left for others to realize that the combined credit of the country cannot finance simultaneously both the tremendous industrial development and the excessive stock speculation. Those gamblers on Wall Street, New York, and on State Street, Boston, appear to be using too much of the available cash and credit.

A RUSH to new alluvial diggings in Victoria proves that all the cream has not been skimmed. Near Tarnagulla, itself about thirty miles from Bendigo, some rich shallow alluvium has been uncovered and several large nuggets have been obtained. The biggest was found on

December 18; it weighed 960 ounces and was 16 inches long, 10 inches wide, and 4½ inches thick. It lay "upon a sandstone bump" and in "puggy ground." 'Pug' is the Australian's equivalent for 'gouge.' Two nuggets weighing 387 and 373 ounces, respectively, were also found, a few feet below the surface. The mining excitement which it has occasioned is called the Poseidon rush.

IT IS PROBABLE that Mr. C. Willard Hayes will be selected as Director of the Geological Survey. While he has been blamed by some for the rather tactless letters that caused several wellknown men to sever their connection with the Survey recently, and while he is not as fully in touch with the Western mining regions as one or two other men that have been mentioned for the post, nevertheless, it is but just to state that he is held in high esteem by his colleagues, who will, therefore, welcome him as their official chief; other men also who are well informed, regard Mr. Hayes as well fitted to succeed Mr. Walcott. The position is one demanding administrative ability more than anything else, for the Survey has become a big bureau quite different from the small scientific corps with which it started under Clarence King. Mr. Hayes is likely to get cordial support from the men associated with him, and this will go far toward ensuring a successful administration. He succeeds to a noble heritage, with great power for good in making geology useful, and we hope that under his direction the Survey will continue to be in the future, as in the past, a scientific guide of the utmost value to the industry of mining.

EVEN THE 'wild cat' has turned in his lair and is emboldened to present an angry front. In the recent issue of one of the newspapers that advertise shady promotions, there is the cartoon of a 'wild cat' facing a number of dogs, representing the magazines that have attacked fraudulent mining practices. In this picture the 'wild cat' looks decidedly belligerent, and is represented as howling that he is "the pioneer of all legitimate industry" and in the description underneath it is asserted that the tendency is to label every mining prospect a 'wild cat' unless it has produced a great deal of money, or is "owned by the Guggenheims." This outburst is the result of a series of attacks on the worst forms of financial chicanery, appearing in certain magazines and written by men who lacked such experience in mining as to make their criticisms effective. The result has been that the local papers have found it easy to retort and everyone of the ephemeral sheets that pose as financial advisers on mining stocks has been enabled to plume itself on a superior knowledge of mining operations. And so the 'wild cat' has won some mistaken sympathy, the promoters of hungry prospects having claimed that every young mine is now labeled in this unkindly fashion until it has been developed into a bonanza. This is nonsense; of course, mines must have a beginning and each starts as a small hole in the ground, the possibilities of which are uncertain, but the mischief done arises from the fact that the promoters of the flood of wretched schemes that are now being advertised in the press offer uncertain prospects at the price of proved mines, and small mines at the valuation of big ones, and worthless claims as rich properties. A 'wild cat' is not an unpretentious prospect, it is a vicious fraud. Among the signs by which you may know him are these: "Mountains of ore;" "Getting richer with depth;" "Veins are coming together;" "Richer than the Calumet & Hecla, or the Homestake;" "Will pay when a mill is built;" "Has been experted by the well-known Colonel Smith and Professor Bunkum;" "An investment, not a speculation;" "Double your money in two weeks."

Calumet & Hecla.

The enlargement of the property of the Calumet & Hecla Company by the purchase of a major interest in the Osceola and Allouez companies is an important event. Control of the Centennial is also stated to have been secured. The Allouez is a young mine that has been a success from the time the Kearsarge amygdaloid copper lode was cut at 1,400 feet, while the Centennial is a property with a checkered history that has recently become profitable by getting the Kearsarge lode at 3,000 feet, after many vain efforts to win dividends from the Calumet conglomerate and the Osceola amygdaloid lodes. The Osceola also found the Calumet conglomerate unprofitable, and then exploited the amygaloid bed to which it gave its name. In this case likewise the future of the mine is largely dependent on the Kearsarge amygdaloid, which has been developed by the Osceola through several shafts. The work of the last five years has emphasized the preponderating importance of the Kearsarge lode, which is now the source of remunerative production in a large group of mines, notably the Wolverine and the Mohawk, besides those above mentioned. The Calumet & Hecla owns other property in Keweenaw county, and is doing exploratory work in several places, so that collectively it now controls an enormous extent of copper deposits of a profitable kind. This means that it will continue to be the decisive factor in American copper production; by the acquisition of new mines to balance the gradual exhaustion of the Calumet & Hecla itself, the company will be able to maintain an aggressive position against any attempt to control copper prices by the Amalgamated people, that is, Standard Oil. Incidentally the change in the management of the Osceola will take the selling of its copper from the United Metals Selling Co., an Amalgamated concern; for the Calumet & Hecla has its own selling agency. The United Metals Selling Co. has been a useful tool of the Amalgamated in some of its predatory enterprises, so that this change is not to be regretted. It is pleasant to note that locally the increasing influence of the Calumet & Hecla management is viewed with favor. Although secretive in regard to its technical practice, and therefore rather ungenerous to professional men and to those who try to win a reputation by publishing useful information, the management has been always recognized as honorable and humane, setting an undoubted example in these respects. In a day of reckless finance and corrupt practice, it is a matter of some importance that a company like the Calumet & Hecla should retain leadership in the Lake Superior copper region. Long may it prosper.

A Professional Matter.

A nice question has arisen in connection with Greenwater. If a mining engineer examines a mine or a number of mines in any given district, should he express his conclusions concerning the district gratuitously in print? For instance, Pope Yeatman, Seeley W. Mudd, and Walter P. Jenney have examined Greenwater in behalf of various clients. It is a notorious fact that a great deal of stock-jobbing of the worst kind is being perpetrated on the basis of some of the copper prospects in that region. Ought these engineers, or others similarly informed, to warn the speculating public? We shall try to answer this self-imposed query, in the hope that some of our readers will help us to clear a nice point in professional ethics—if ethics be not too big a word. In the first place, the engineer gets his information at the expense of his client, and he cannot make use of it without the client's permission—at least he should not do so for a reasonable period, and then only if the publication does not work harm to the interests of that client. As a client usually ceases to have any interest in a camp after he has received an unfavorable report, it is evident that he may be expected to grant permission for publication. If, on the contrary, the report is favorable, it is to the interest of the client to have kind things said of the camp—provided he has secured all the property that he wants. If he is planning to acquire more, he will want things kept very quiet. So much for the client; now for the engineer. Should he express an opinion in print, the client having no objection? One man will argue that it is foolish to give advice for nothing to people whom he does not know, and another will add to that point of view that it is a mistake for the engineer to risk his reputation by committing himself publicly to any decided opinion. To this we would answer that while it is true enough that people who put money into mining schemes without professional advice deserve no consideration from the professional man; and although the public that runs after wild schemes does not contribute to the living expenses of the mining engineers, and therefore no sympathy is likely to be wasted by the latter, nevertheless, this is the argument only of the sort of man that never heard of civic duty or any other code save the one that is emblazoned with the shekel. The public may not deserve much of us in these matters, but each of us owes something—and something big—to the community in which we live. That is the basis of civilization. However, let us come nearer home. The idea presented to many professional men is that it is a mistake to run the risk of a blunder by publishing an opinion except for a fee; the fee pays for the risk. You may be wrong and then you have injured your reputation. But, my dear Sir, you never make a reputation unless you risk it. Reputations are made by the exercise of good judgment and the expression of correct conclusions; if you are to avoid responsibility, go and run a chicken ranch. The engineer is a scientist and a citizen; as a scientist he states the truth and as a citizen he recognizes his obligations to the community; if he is untruthful or if he is neglectful of his civic obligation, he is a renegade to his profession. And this is no exaggerated language; those of us who have received a technical education and a scientific training owe it to our self-respect to have higher notions of duty than a hod-carrier or a State legislator. It is the old slogan "*Noblesse oblige.*" And it has its more practical application; for reputations are undoubtedly made by the expression of decided opinions that prove right, and one of the best ways of getting away from the undistinguishable crowd, away from the 'and others' and the 'also ran,' is to publish a correct diagnosis of a new mining district, whether favorable or unfavorable does not matter, as long as it is based on sufficient evidence.

Zinc Ores.

The recent discussion as to whether the silicate and carbonate of zinc should both be admitted free of duty under the designation of 'calamine' has been decided in the affirmative by the Board of General Appraisers of New York, in opposition to a ruling of the Secretary of the Treasury made by him a year ago. At the same time it was decreed that the sulphide (blende) is not a metallic substance under the meaning of the new law, and that it may enter the United States without penalty. This will please mine owners in Mexico, without doing injury to anyone on this side of the border. According to the revised tariff of 1896 an *ad valorem* import duty of 20 per cent was placed on all minerals that contain 'metallic' values, but a specific exception was made for 'calamine' ores. It was contended by several experts that only the silicate ore is 'calamine' in the correct meaning of that term. Other experts testified to the contrary. In the end it was decided, as stated, that the old interpretation of the term 'calamine' was intended by the framers of the law to include both of the oxidized ores, which occur in close association and are difficult to distinguish. Incidentally, we note from an article by Mr. Jesse A. Zook, in the Joplin *Globe*, that the zinc miners of Missouri were not behind the movement to shut out the Mexican and Canadian ores, but that it was instigated by a metallurgist representing a European smelter, to whose interest it was to spoil the American market for the Mexican and British Columbia ores.

It is satisfactory that the matter has been settled. 'Calamine' becomes a trade term for the two minerals known in science as 'calamine' and 'smithsonite;' in the same way 'pyrites' is used as an industrial equivalent for the mineral 'pyrite,' and 'barytes' for 'barite,' the old form doing duty in commerce after it has been discarded in mineralogy. It is a curious fact that while in America 'calamine' stands for the silicate, and 'smithsonite' for the carbonate, the reverse is the case in England and Germany; there the silicate is 'smithsonite,' and the carbonate 'calamine.' Those who learnt their mineralogy in Europe, have often been confused by this transposition. Prior to 1846, when Dana transferred 'calamine' to the hydrous silicate of zinc, the nomenclature was the same on both sides of the Atlantic.

Personal.

PERCY L. FEARN is in Costa Rica.

CARL HOFFMANN is at Mexico City.

EDGAR A. COLLINS is visiting San Francisco.

CHARLES BUTTERS is expected back from Mexico.

ERNEST WILTSEE is investigating mines in Peru.

H. SPANGLER, of Denver, is now at Hercules, Nevada.

JOHN S. P. SAMBORNE has left London to proceed to Mexico.

HOMER WILSON of Goldfield, Nevada, has been in San Francisco.

H. S. CHAPMAN, formerly at Bodie, is now at Greenwater, California.

J. B. RISQUE, manager of the Utah Consolidated, is in New York.

J. LEWIS TONKIN is now with the Mysore Gold Mining Co. in India.

H. A. LEE now resides at Salt Lake City, his office being in the Dooly Block.

JOHN C. MONTGOMERY, of New York and Denver, spent a few days in San Francisco.

J. K. TURNER is consulting engineer to the Combination Fraction Co. at Goldfield, Nevada.

GEORGE A. SCHROTER, consulting engineer of the Dolores mine, Mexico, is visiting San Francisco.

I. B. EMPSON, metallurgist for the Guanajuato Development Co., has been visiting Pachuca, Mexico.

ARTHUR G. COLEMAN is on his way from Australia to inspect the Raub mines in the Malay States.

LEWIS T. WRIGHT, the manager of the Mountain Copper Co., is leaving for a short holiday in England.

JUAN F. BRANDES visited San Francisco, on his way to Sonoro, Mexico. He returns to Europe in April.

A. CHESTER BEATTY will go to Brussels shortly, in connection with the Congo business of the Guggenheims.

R. W. FOSTER, recently superintendent for the Sevier Consolidated Mining Co., Utah, has gone to Cobalt, Ontario.

J. B. PITCHFORD, recently mechanical engineer at the Randfontein mines, Johannesburg, is now living at Berkeley, California.

E. P. MERRILL, of Virginia, has been appointed general manager of the Real del Monte y Pachuca properties, at Pachuca, Mexico.

G. M. GOUYARD, of Denver, has been appointed consulting engineer and manager of the Bonanza Belt Copper Co., at Johnson, Arizona.

F. W. BAKER, chairman of the Venture Corporation Ltd., has been dangerously ill. He is, we are glad to state, recovering satisfactorily.

HAROLD V. PEARCE, manager of the Argo smelter at Denver, who has been taking a holiday at Monterey, spent a few days in San Francisco.

JOHN M. DAUGHERTY, of Omaha, and THOS. A. VARDEN, of Sacramento, Cal., both of the American Mining & Development Co., are at Salt Lake City for a few days.

CHARLES S. MORRIS has resigned as superintendent of the Utah Consolidated smelter, near Salt Lake City. He will be succeeded by ALEXANDER LAIST, formerly of the Washoe smelter at Anaconda, Montana. Mr. Morris was with the Utah Con. for about four years. He goes to the Cerro de Pasco mines in Peru, South America, to occupy a similar position under ROSCOE H. CHANNING.

Dividends.

On March 4 the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 114 of $180,000. This makes the amount of dividends paid since January 1, $540,000, and total to date $8,406,000.

[We shall be glad to receive notification of dividends declared by other mining companies.—Editor.]

Books Received.

'Report of the Director of the Mint' upon the production of the precious metals in the United States during the year 1905.

U. S. GEOLOGICAL SURVEY.—'Black Sands of the Pacific Slope in 1905' by David T. Day and R. H. Richards. This is a pamphlet of 80 pages, describing the experiments made in the concentration of the heavy sand occurring in placer deposits.

'The New Zealand Mining Handbook.' Issued by the Minister of Mines. Edited by P. Galvin. This is a volume of 585 pages, giving a general account of mining operations in New Zealand. It is profusely illustrated and full of interesting matter.

'The Six-Chord Spiral,' by J. R. Stephens. A little book containing complete information regarding the location and construction of spirals, with especial reference to the six-chord spiral, which is an ordinary multiform compound curve of six arcs of equal length, whose degrees of curvature increase in the order of the natural numbers, and so arranged that the seventh arc always exactly coincides with the main circular curve. The Engineering News Publishing Co., New York. Price $1, board; $1.25 cloth.

Mining Summary.

ALASKA.

The Hadley smelter is again operating at full capacity, the mines near the town are being worked, and both the mines and smelter are advertising for men.——The mills at Treadwell have started again, a shipload of coal having arrived. ——It is announced that a smelter with a capacity of 500 tons per day will be built on Resurrection bay near Seward and will be ready for operation by the time the Alaska Central railroad reaches the Matanuska coalfields, which is expected to be early next year. This announcement is made by J. E. Ballaine, who attended a meeting of Alaska Central directors and other railroad officials, in Chicago. The smelter company is an independent corporation, but is being projected jointly by the men behind the Alaska Central, and the Hubbard Elliott and the Knight Island copper companies.——The owners of the Groff mine at Chichagoff will build a five-stamp mill in the spring. Ten men are working at the property, and ore is shipped regularly to the Tacoma smelter that is said to average $150 per ton. Drifts have been run on the vein for 200 ft.——It is reported that the Detroit-Yukon and Canadian-Klondike mining companies, composed of Detroit capitalists, are closing negotiations for the amalgamation of the two companies with the Guggenheim Exploration Co. These two companies were formed five years ago, and have been accumulating gold-producing properties in the Canadian Yukon until they now own 45 square miles.——Estimates place the probable production of the Tanana for this winter and summer at $12,000,000, which will mean an increase of $3,000,000 over last year. It is believed that the Chatanika will prove the richest portion, as an ancient channel is being traced there from Cleary creek.

ARIZONA.

YAVAPAI COUNTY.

Improvements in the United Verde mine and smelter are constantly being made. The capacity of the smelter has recently been increased, and the furnaces are being enlarged. Already there are five 500-ton furnaces in the plant. The most urgent problem at the mine is how to handle the immense product. The amount of ore now blocked out is probably enough to last for 30 years.—— Mining operations throughout the whole Jerome Verde copper belt are very active. A number of promising properties in the immediate neighborhood of the United Verde are being developed. The North Verde, the Verde Grande, the Cleopatra, and the Black Hills group of claims are making the most satisfactory progress.

CALIFORNIA.

AMADOR COUNTY.

The Fremont mine paid its first dividend last month, amounting to two cents per share. The capitalization is 200,000 shares. From the present outlook, the mine should continue to pay dividends at regular intervals.——The Hazard mine is to be worked as soon as supplies can be secured. This property is situated between the Fremont and Bunker Hill mine. J. R. Poundstone is in charge.—— The Keystone at Amador City is still idle, on account of the breakdown of the air-compressor. Some trouble is experienced in keeping down the water, with the machinery available. A number of the miners are leaving the camp.

NEVADA COUNTY.

(Special Correspondence).—Since the heavy storms are practically over, it seems that every part of Nevada county is receiving more than the usual amount of attention, and activity is in evidence everywhere in the way of mining.—— A number of mining men are in the field examining properties.—— An important strike has been made in the Telegraph mine, 44 miles north of Nevada City. Ore encountered runs as high as $1,000 per ton. The character of the lode is the same as that of the Tightner mine of Alleghany. The chief development is a long tunnel, with modern surface improvements, $100,000 having been spent upon the property in the last five years. The gravel deposit has given rich returns in the past, but the new strike is on a quartz vein. This was a blind lode, for which the company has been making a long search.——Work has been resumed upon the Blue Tent gravel mine on the South Yuba river, six miles above Nevada City, under the direction of Oscar Jones. A tunnel is to be run to develop a large tract of virgin channel which cannot be reached through old workings. Many years ago the Blue Tent was a prominent hydraulic mine of the county, but since an embargo was placed on that industry, has been worked as a drift mine. It has produced many hundreds of thousands of dollars, with only a comparatively small amount of the present workings developed.—— A seven-foot lode of ore has been encountered in the shaft of the Murchie mine. As far as can be judged by the work done it is an entirely new discovery.—— A rich strike has been made upon the Morning Star mine, held under bond by the James Brothers, on what is known as the Mother Mitchell ranch, a few miles west of Nevada City. A prospect shaft was sunk 30 ft. on a lode. It was in the drift from this shaft that the rich

California.—Showing Position of the Counties.

rock was found. The lode is from 15 to 18 in. wide, thickly peppered with gold, and gives promise of running well.—— A rich strike has been made in the old Mountaineer mine, about a mile south of Nevada City. Superintendent Campbell states that the new shoot is making for the Customah mine. This makes the discovery an important one for that mine, as well as the Mountaineer.—— Martin Vanberg, of Washington, is developing a valuable property on Canyon creek, about 25 miles above Nevada City. His property adjoins the Arctic, which is proving a splendid producer, and upon which a new strike has recently been made. The vein on the Vanberg claim is said to be from 15 to 20 ft. wide, well defined, and averaging $5.20 per ton.——The famous Tightner mine still continues to make rich strikes. The last one made was in the south drift about 100 ft. from the shaft.—— The Giant King mine, about 25 miles from Nevada City, and near the town of Washington, is being opened by the Co-operative Exploration D. Co., and gives promise of developing into one of the biggest low-grade propositions in the State. A tunnel 570 ft. long has been driven into the hillside, which cuts through the lode. The vein is 97 ft. in width from wall to wall, every foot of it being quartz. It is expected a new 20-stamp mill will be erected upon the property by the first of next August.

Nevada City, Mar. 1.

SISKIYOU COUNTY.

The Great Johnnie mine at Quartz valley, formerly known as the Two Bit, and now owned by David Bedit and J. W.

Eubanks, is showing up well. Two tunnels have been driven, each over 100 ft. long, and a good vein is exposed. ——It is understood that the Medina company has another extension of one year on its bond of the mines at Oro Fino, and will continue work.——The coal mine east of Medford is showing up well. A nine-foot vein is reported, the permanency of which has been proved. The owners of the Blue Ledge mines are interested in this property.——The mill of the McKinley company, on Humbug, is running again.—— The Mt. Vernon Mining Co. has let a contract to run a long tunnel on its lower vein, which is about three feet wide.—— The new pump, hoist, and ore-bin at the Sheba mine on Patterson creek are about finished, and all machinery will soon be in place. This company is now supplied throughout with a splendid new equipment, and the mill will be running in 30 days. N. E. Graves is the superintendent.——Tunnel No. 5 in the Helena quartz mine, near Callahan, has reached the ledge and crossed it. The new cyanide plant has been completed, in spite of the scarcity of labor, and the milling operations will soon start.——The Fernandez hydraulic mine at Cherry creek has commenced operations with two giants, and the Sunset, just below it and near Deadwood, is running one giant. There is plenty of water and a long and prosperous run is expected at each of the properties.

The Hawkensville ditch, has been repaired across Yreka flats to Rocky gulch. The ditch covers some very rich ground, and will be used as long as the water holds out, which will be until about July.——The Spengler mine at the mouth of Humbug creek is being worked. Water is being used for hydraulicking and a good deal of ground sluicing is being done to uncover the richer gravel in order that work may be kept up when the water supply becomes low.

TUOLUMNE COUNTY.

(Special Correspondence).—There is promise of much activity at the North Star mine. Although it was contemplated to have the mill in operation, W. G. Phipps, the superintendent, has confined the work entirely to development, and good orebodies have been uncovered. At present driving south on the 200-ft. level is in progress.——Work is to be resumed at the Uncle Sam mine, near Arastraville, the coming week. Driving and sinking the main shaft will go on at the same time, and the ore extracted will be crushed in the Dreisam mill. The average width of the vein is 20 in., and it is expected the ore will go $15 per ton free gold.——The new incline shaft at the Confidence mine is down 370 ft., and sinking continues. A cross-cut is being driven toward the hanging wall at the 300-ft. level. A tramway 1,200 ft. long, running from the new shaft to the mill, was recently completed.——There is an unauthenticated rumor in circulation to the effect that ore of remarkable richness has been uncovered in the Soulsby mine, operated by the Bagdad-Chase Mining Co. Grading for a tramway to connect the Davidson shaft of the Soulsby with the mill is in progress.——The contract for extending the adit at the Jewel-Fay mine 100 ft. has been completed, and A. Davidson, of Fowler, Fresno county, is here making arrangements for continuing development work. The adit is 200 ft. long and exposes considerable good-grade ore. Some thought is being given to erecting a mill in the near future.——Development work was commenced a few days ago at the Turnback mine, situated near Tuolumne on the creek by the same name. Thirteen sacks of unselected ore from this property yielded $45 per ton. This test was made some time ago by local people who contemplated purchasing the property, but before they began negotiations in earnest for the purchase, others obtained the property by bond. The latter erected a two-stamp mill, but about the time of its completion dissatisfaction arose, activity ceased and the bond was forfeited. Recently, outside people acquired the property and are now developing it.——Work is to be resumed at the Duchess mine, situated near Parrot's Ferry.——A new body of high-grade ore has recently been uncovered in the Mt. Lily mine, near Columbia.

Tuolumne, March 3.

YUBA COUNTY

A careful survey has been made of the ground in dispute between the dredging interests of Oroville and the Anti-Debris Association, and an apparent settlement of the matter has been reached. The solution of the problem agreed upon, was the construction of a system of barriers along the outlets of the various ditches leading from the dredges to the river. Small settling reservoirs and dams will be constructed. No further action will be taken as far as the injunction suits are concerned, and the work of construction will begin at once, under the direction of an engineer of the Anti-Debris Association.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).— The Georgetown district is booming, and the working force will be trebled within the next 60 days. During the past week the Mendota group of claims has been transferred to a syndicate of Eastern capitalists, who are represented by J. L. Gordon, of Denver. The consideration is given at $350,000. A contract was awarded the first of this week for sinking the main shaft an additional 300 ft. As the lower four levels are filled with water, the pumps have been put into commission, and it is expected to have everything in readiness for breaking rock within 10 days. This shaft now has a depth of 1,200 ft. It is known that large orebodies exist below the fourth level, and the production promises to be heavy. A raise is to be put through from the Victoria adit level to the upper Frostberg workings, a distance of approximately 400 ft. The Mendota group has been one of the steadiest producers of this section for over a quarter of a century, and is the greatest lead and zinc proposition in Clear Creek county, if not in the State. The new company will start work upon a concentration plant with a capacity of 150 tons per day. John Old, of Georgetown, has been appointed resident manager.—— A rich strike has been made in the Silver Cloud workings, situated on Sherman Mtn. In running a drift for a distance of 70 ft. a two-foot body of lead ore has been uncovered. Stoping has been put under way and a record breaking production is promised.—— Work has been resumed on the Plato mine, situated on Griffith Mtn. The adit, in a distance of 85 ft., has been cleaned out and retimbered, and in the breast there is now showing a three-inch streak of ore which gives assays of 20 oz. gold per ton. Wm. Aldred, of Georgetown, is the owner.—— Shipments of concentrate were started this week from the East Griffith mill. The material is sold to the Georgetown sampler, and the manager of that institution states that the finished product is the cleanest that he has ever handled. The concentrate averages $55 per ton. W. D. Hoover, of Denver, is the manager.——Ground was broken this week for the new power-building and milling plant to be constructed by the Capital Prize company. Owing to the boiler giving out at the old plant it became necessary to suspend operations, but W. M. Cooper, the manager, states that he will have the new plant in operation inside of 60 days. The machinery has been ordered and is expected to arrive inside of two weeks.—— The Electric plant of the Two American Sisters Mining Co. is now furnishing power. The company's mill is running on full time, and a fine quality of concentrate is being turned out. Wires are being run throughout the Columbian Mtn. section in order to furnish power for a number of other large operators. J. J. White, of Georgetown, is the general manager of the enterprise.—— It has just been learned that the Arapahoe group of 12 claims and two millsites were purchased by the Transcontinental company. The deal was engineered by Rees C. Vidler, the general manager, $40,000 having been paid for the holdings. The heading of the Vidler tunnel is now nearing Arapahoe ground. The company's mill is running on full time, being fed upon ores found in the Flossie vein workings.—— A contract has been awarded by Gileen & Johnson for the driving of the adit on the Hidden Treasure an additional 100 ft. These holdings are situated in East Argentine, and lie in close proximity to the Arapahoe group.——A new and important strike has just been made in the Cliff mine, situated on Democrat Mtn. At a distance of 300 ft. from the portal of the lower adit, an 18-in. streak of 60 oz. silver ore has been uncovered. Blind drifts are now being run. As this is practically a surface pocket, a large output will undoubtedly result. Manager Chas. Estelle is employing a good force of men in carrying this

stope, as well as the one 800 ft. from the portal of the adit. —— The Lucky Hesperus is the scene of one of the richest strikes made in many years on Democrat Mtn. In running a cross-cut under the old workings a four-inch streak of 600 oz. ore has been exposed. For some time the operator had been following a body of quartz measuring four feet in width, and it is believed he has cut into one of the old-time bonanza pockets for which the mine was famous a few years ago.——Henry Seifried, of Georgetown, has bonded and leased to Wm. Morgan, of Idaho Springs, an undivided one-half interest to the Brazil group of 15 elaims, situated in the Freeland district. The bond calls for $10,000, and runs for two years. Mr. Morgan in turn transferred his privileges to the 3,006 Leasing Pool, whieh is being financed by Idaho Springs business men.—— Paul Raddatz has sold to A. H. Brunke, of Denver, the Fillibuster, and Fillibuster No. 1, 2, and 3 lodes, and the Three Friends property, situated on Silver Mtn. A company is now being organized, and an energetic campaign of development is promised for the near future.——The Colorado Central mine, with a production of $10,000,000 to its credit, is producing a heavy tonnage of ore. Ten sets of lessees are at work, and all are in pay-ore. The returns vary, running from 70 to 280 oz. silver per ton. F. A. Maxwell, the manager, is employing a good force of men, and is stoping on a big body of zinc in the Sleepy drift run from the Equator adit. The product is concentrated at the Santiago mill.

Georgetown, Feb. 28.

OURAY COUNTY.

The differences between the miner's union and the owners of the Gold Lion have been settled, and work is progressing at that property. The tunnel is now in about 800 ft., through heavy ground. Much water has been encountered.——The car of ore shipped from the Jonathan returned $7,660.——The Chipeta tunnel is going ahead at the rate of 75 ft. per week. It is in 1,600 ft., and when 400 ft. more is added, a raise will be run 150 ft. to the quartzite, where it is expected that a good body of ore will be encountered.

SAN JUAN COUNTY.

The Old Lout mine has been sold to George Crawford and associates, of New York. The group includes the Old Lout, Michigan Girl, and other claims, and is situated at the head of Poughkeepsie gulch, near Mineral Point. This property was located in 1876, and has produced $300,000 in silver, reaching its maximum output in 1884. Subsequently it was sold to a London company, which ran a tunnel 1,800 ft. in length, which never cut the vein. The ore was a complex one, carrying lead, zinc, copper, and bismuth.——About 40 men are employed at the Hamlet mine and mill. Some high-grade copper ore has been recently encountered.——The Gold Prince mill at Animas Forks is dropping 30 stamps. W. Z. Kinney is the manager.—— The Grand Mogul mill at Gladstone is running, following a period of inactivity. The ores of the Mogul are low grade and refractory, carrying lead, zinc, and iron, but the mill is handling it successfully.——The tunnel at the California Mtn. mine is in 800 ft. In another 1,200 ft. it will cut the Mountain Queen vein.——The Alethea mine, at Sultan Mtn., is one of the latest acquisitions of the Detroit & Colorado company. This property was worked 20 years ago by lessees. The property is being worked, and the vein, which has been narrow and rich, is increasing in size. A new compressor and other machinery has been ordered.——The Green Mtn. mill is being overhauled and remodeled. C. J. Garvin is manager.——The Henrietta mine is shipping to the Ross smelter, and the Gennessee is opening the road in order to begin hauling.——The Silver Lake mill is completed. It is built in two units, in order to treat Silver Lake ore and material from the Aspen group.

SAN MIGUEL COUNTY.

The heavy snows caused a break in the cable furnishing electric power to the pumping station of the Tomboy mill, at Ptarmigan lake, which resulted in a temporary shutdown of the mill. The line supplying power to the Camp Bird is also out of repair and giving a lot of trouble; and for some days there was no communication between Ouray and the outside world.——The uranium mill, near the western boundary of the county, has been idle for some weeks, awaiting the arrival of a new boiler. This plant has been treating ore running from 2 to 4% uranium. The ore is obtained from pockets, containing from a few pounds to several tons. The process consists of crushing, roasting with soda, leaching, and precipitation, the treatment being similar to that used at the Newmire vanadium mill.

NEVADA.

ESMERALDA COUNTY.

(Speeial Correspondence).—Blair is a new town at the terminus of the Silver Peak railroad, which was built last fall from Blair Junetion, on the Tonopah & Goldfield railroad, into the Silver Peak and Red Mountain mining districts. Blair is three miles north from the old town of Silver Peak. It has water and sewer systems, electric lights; and a hotel having modern appliances is nearly eomplete. On a saline flat to the east are hot-water springs and the plan is to bring this water at its high temperature into the buildings for domestic use. On the same salt flat is the crater of an extinet volcano, rising to approximately 1,000 ft. above the surrounding plain. To the west are the Silver Peak Mtn., a range rising from 4,000 to 6,000 ft. above sea-level, trending nearly north-south, and which is made up of limestone and sehist. There are also dikes of diabase, cutting through the country. Locations were made and mines opened here nearly 50 years ago. Perhaps the most noted among them were the Vanderbilt and the Drinkwater, both of which operated stamp-mills. The Drinkwater was financed and operated by Samuel J. Tilden and associates, of New York, and the old workings, roads, and buildings, whieh they left, are today interesting reminiscences of that historic period in Nevada.——The revival of mining in Silver Peak range dates from 1905, when the great power-transmission line was stretched from Bishop ereek, California, to Goldfield and Tonopah. Silver Peak was in the path of this line and enterprising parties, seeing electric power at the door of the old district, took steps to re-open the mines and erect mills. The Pittsburg & Silver Peak G. M. Co. acquired large holdings along the strike of one of the prineipal vein-systems of the range, including the old Drinkwater mine; installed two air compressors, both electrically driven, and started work with air-drills. The same company built the 17 miles of railroad into the camp from the main line, over which trains have been operating since last October. A millsite has been seleeted at Blair, the exeavating and mason work are in progress, and the equipment for a 100-stamp mill and eyanide plant is on the ground, most of the maehinery having been furnished by the Power & Mining Machinery Co., of Milwaukee.—— Equipment for a 2½-mile aerial tramway line has been ordered from Leschen & Sons, and this will be erected to convey the ore from the mine to the mill. At the upper terminal of the tramway, three erushers will be installed to reduee the ore to 1½-in. size before it is conveyed to the mill. The crushers are on the ground. The mill will be built in three seetions, for stamps and plates; classification; and cyanidation. The ore is a gold-quartz and it is ealeulated that 50 to 60% will be recovered by amalgamation. The pulp after passing over the plates will undergo settling, classifying, and dewatering, effecting a separation of the sand from the slime. The sand will be cyanided in the usual way, the slime to be eyanided with Merrill's slime-filter presses. The mine is opened by a system of cross-cuts and adits. The main working level, which cross-cuts to the vein, is being double-tracked and equipped for eleetrie haulage. This leads into the recently opened section of the mine and these new workings will be connected with the old and extensive workings of the Drinkwater mine. The erushers and upper terminal of the tramway will be established near the portal of the main working level. While the two bases of operation are widely separated, the workings are considered on the same vein. M. L. Effinger is managing director for the company; J. L. Freeburn, general manager; A. J. Logan, superintendent. Geo. O. Bradley is consulting mechanical engineer, and C. W. Merrill, eonsulting metallurgist.——The Silver Peak-Valcalda M. & M. Co., in which O'Meara Bros. and J. T. Lynch, of Salt Lake, are in control, has the Valcalda mine, situated higher

on the range than the Pittsburg. Its holdings cover a quartz lode, which dips to the west at 25° and ranges in width from 16 to 25 ft. The vein carries gold, which occurs partly free and partly in pyrite. The property is opened by an incline conforming to the dip of the vein, with drifts run both ways in ore from 100-ft. stations. The present depth of the incline is 350 ft. Equipment is on the ground for a 10-stamp mill and cyanide plant. This includes a tube-mill for re-grinding the pulp after it leaves the amalgamating plates. It will then be cyanided in connection with a Hendryx agitator. The mill will be erected as soon as possible and it is expected to be put in operation by June 1. An air-compressor is in use for drill work, being electrically driven. All the power used here is derived from the Bishop creek electric line which crosses the country at the old town of Silver Peak. The entire property of the Valcalda company is under the superintendency of Curtis L. Knight, of Salt Lake City.

Silver Peak, Mar. 1.

(Special Correspondence).—The Mt. Grant district, 50 miles south of Yerington, and four miles from the east fork of the Walker river, has a new camp which is being explored by Dr. B. A. Burger and associates of San Jose, Cal. Ore has been found in a contact vein in lime and porphyry. The ore is a quartz-porphyry, carrying gold, silver, and galena. This locality is well watered and timbered. Parties interested contemplate erecting a small stamp-mill, with plates and concentrators.

Yerington, Feb. 22.

(Special Correspondende.)—The Nevada-Rockland M. & M. Co., eight miles southeast from Pine Grove and 50 miles south of Wabuska, the nearest railroad station, has a well-defined vein in rhyolite and diorite, carrying gold ore in a quartz gangue. The mine is opened by three adits, all connected, and a 100-ft. winze from the lowest level. There is said to be over a mile of underground work. A five-stamp mill was operated for some time and now a new milling plant is being erected, having crushers, rolls, screens, and cyaniding equipment, which will have a capacity of 100 tons per day. C. I. Baxter is manager, and M. M. Mendenhall constructing engineer. The Colorado Iron Works is furnishing the equipment.

Wabuska, Feb. 23.

LINCOLN COUNTY.

(Special Correspondence).—The amount of work done on the Annette property proves it to be the continuation of the vein cut in the Spokane shaft and owned by the Southern Nevada M. & M. Co., which has the same character of copper-stained ore on the surface, and also in the cross-cut.—A seven-inch Cornish pump has been ordered for the Drake shaft on the Quartette Mining Co., with a capacity of 200,000 gallons per day. These workings are on the Hidden Treasure claim adjoining the Cyrus Noble property.——Activity is shown on the Gold Beam and Majestic Bull Frog groups in the northern part of the district; a depth of 80 ft. has been reached on the Gold Beam, where some good copper and iron-stained ledge matter has been encountered.——At the Red Cliffe mine, situated about two and one-half miles east of Searchlight and adjoining the Boston group of the Quartette Mining Co., a recent discovery of high-grade ore has been made. The ore was first found in a shaft some 80 ft. deep, and the indications were that the shaft had cut the extreme western end of the ore-shoot in the vein. Since then the owners, I. F. Smith and John Jarvis, have opened a vertical shaft to the east of the original strike and at a depth of about 30 ft. struck ore. The quartz shows free gold and the general run of the vein is good. Sufficient development work has been done to show the hanging and foot-walls.——Arrangements are being made to resume operations on the Golconda.——The property of the Searchlight Gold Dollar adjoining the Golconda and Gold Dyke mines, will soon be in active operation; advices from New York state that they are arranging to contract the work of sinking to the water-level.——Good ore has been encountered while drifting eastward from the 300-ft. level in the Venus mine belonging to the Black Hawk Co. of El Dorado cañon. This same company is installing new machinery on the Rand property in the same section.——The Searchlight-Wyoming M. & M. Co. has encountered a big flow of water at the 300-ft. level, where it is cutting a station, and intend to cross-cut north to the vein and resume sinking after the pumping plant has been installed.——It has been announced that the Searchlight-Barnwell Railroad Co. will reach Searchlight April 1, and all the business men and citizens are preparing to celebrate on that day. They are now working a force of 400 men and the remaining distance to be covered with steel is eight miles.

Searchlight, Feb. 21.

SOUTH DAKOTA.

CUSTER COUNTY.

(Special Correspondence).—The Saginaw Mining Co.'s property is situated about eight miles northwest from Custer. At a recent meeting new officers were elected. L. P. Woodberry retired from the presidency, being succeeded by L. W. Herber. The directors are: Louis Hahn, H. N. Wagg, Ben Eleber, and Geo. S. Thompson. The meeting was held in Chicago on Feb. 4. The property consists of 20 claims, upon which good gold-bearing veins have been exposed by open-cuts and shallow shafts. The Saginaw mine has a shaft down about 400 ft., and drifts cut three veins of good ore, the largest one being 13 ft. across, and averaging about $10 per ton gold. The mine is well equipped with buildings, and a good steam-hoist, and the company announces its intention to put up a mill of 100 tons capacity during the coming summer. The Custer & New York Mining Co., formerly the Newark, has been erecting buildings and preparing for deep sinking. They are at present cross-cutting the vein by driving on the 100-ft. level. Chas. Waite, the president, is now in the East to purchase machinery for the mine. Dan Baker is superintendent.—— The mica factory belonging to the Westinghouse Electric & Mfg. Co. is running full capacity, and employs about 20 girls and boys, trimming, splitting, and preparing the mica for shipment to Pittsburg. It employs 20 men at the mine, and is taking out about 5,000 lb. of mica per day. J. Gurten is in charge of the factory, and Joseph Pyne is superintendent of the mine.—— Oscar Alpetter, of Milwaukee, and R. B. Martin, of Madison, Wis., were here on Feb. 14 looking at the mica mines, with a view to establishing a depot for the purchase of the product of the small producers in this vicinity. For this purpose a meeting was called at which all the owners were invited to discuss the subject. It is the intention to carry out this plan. Fifteen owners of mica mines attended the meeting, and the conference was satisfactory.

The Ivanhoe is running full blast and showing up well. Herman Ratte is the superintendent.—— The Clara Belle Co. is driving on the 250-ft. level in the new vertical shaft to strike the orebody in the old incline. It is daily expected to strike the vein, when the mill will again be started. Frank Hebert is in charge.—— The mills running on the silicious ores of the Bald Mtn. district are closed down on account of the strike.—— The Homestake, with its 1,000 stamps, is running, and has never had a strike.——The Branch Mint Mining Co., whose property is near Galena, 12 miles east of Deadwood, has about completed the 200-ton plant. The railroad which connects the mine and mill is five miles in length, and it is announced that they will continue it on to Deadwood in the spring. This road will pass near the Two Bit, Golden Crest, Lexington Hill, and Spruce Gulch mines, and will be a boon to the district. There seems to be no immediate prospect of an agreement between the mine owners and the miners in regard to the strike now on, and Deadwood feels the strike most keenly.

Custer, Feb. 29.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The Winnepeg Mining Co. will extend its operations on the Hawkeye group of claims and is hiring more men. The adit is in 840 ft. and has intersected a stringer of quartz three feet wide and heavy with chalcopyrite. This is the best copper ore ever found in the Lambert creek section. Concrete foundations have been constructed for a 100-h.p. boiler, a 65-h.p. Russell engine and a 6-drill Leyner compressor, which are expected to

arrive inside of two weeks. A dynamo is being installed for electrically lighting the mine and camp. The adit will shortly be connected with the shaft, when the manager expects to be in a position to ship from 100 to 150 tons of ore per day.——The track of the Belcher Mtn. railway will be cleared of snow immediately, in order to run the train for the delivery of the Winnepeg Co.'s machinery. It is probable that it will soon be required for the haulage of ore to the smelters.——A sleigh-road is being constructed from the Bortle Copper-Gold Co.'s shaft to connect with the main wagon-road down Lambert creek, for the haulage of ore to the bunkers at Lambert siding. The company may ship several hundred tons to the Granby smelter, at Grand Forks, B. C. This ore is an iron sulphide which the superintendent says will assay 2 to 3% copper and a few dollars in gold, with about 35% iron. He also says the developments in the Bortle shaft workings are so satisfactory that the company is formulating extensive plans for deep mining; that in addition to electrically-driven air-drills, a diamond-drill equipment is contemplated, and a small sawmill will be installed on timber land lately acquired by the company.——An ore purchasing and transportation company, capitalized at $200,000, for the haulage of ore in the Belcher Mtn. neighborhood, is reported as being incorporated. Some work was done toward constructing a tram-line around the mountain by parties styling themselves the 'Skyline Tram Association,' and a number of ties were cut; but the work was abandoned, owing to the refusal of right-of-way over some mining ground. The incorporators first mentioned, will take over this tramline.——The Advance Mining Co. owns a group of eight claims, situated in the southeastern part of Ferry county, east of the Sherman range and three miles west of the Columbia river. A quartz vein, with ore assaying $100 per ton in gold, silver, and lead, has been developed by two adits, aggregating 1,400 ft. in length, and a winze which goes down 30 ft. and gives a total depth of 135 ft. on the vein. Work on the property was suspended for want of funds. An assessment of one-half mill per share was levied, and work will be resumed shortly. The company is capitalized at $2,000,000, with shares at a par value of $1 each.

Republic, Mar. 1.

KOOTENAY COUNTY.

(Special Correspondence).—Thomas Golden has purchased a controlling interest in the Northwest Cœur d'Alene Italian Copper company, recently incorporated by a number of Italians who have been developing 10 copper claims in the Priest River country. He has also taken a half interest in a group of five claims from Thomas McCaffery. Under the terms of the purchase the company must run a tunnel 500 feet.

Spokane, Feb. 16.

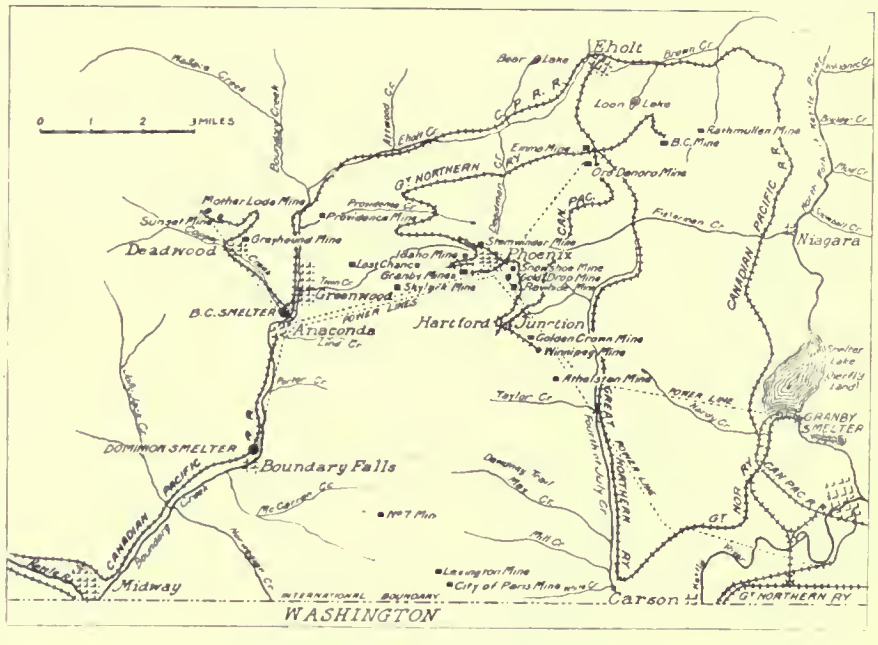
SKAMANIA COUNTY.

(Special Correspondence).—The St. Helens district is in the northwest corner of Skamania, extending into Lewis county. It occupies townships 9, 10, and 11 North, of ranges 5 and 6 East. Tilton, the terminus of the Tacoma & Eastern railroad, is 25 miles north from the district. Castle Rock, on the Northern Pacific, is 50 miles west. The district is situated just north of Mt. St. Helens. The country rock consists of syenite, granite, and diorite, all of which are covered in most cases by volcanic ash, but often the formation has been exposed by erosion. The country is heavily wooded. There are veins along the fault planes and contact veins between syenite and rhyolite. These veins as a rule stand vertically. Their width varies from 4 to 100 ft. The gangue is often mineralized country rock, or it may consist of quartz and quartzite. The ore is chalcopyrite and bornite. Much of it is rich enough for shipment, when railroad transportation is provided. Extensive development has been accomplished by the Cascadia Mining Co. This company will now be able to ship a considerable tonnage of ore. The Sweden and Norway groups are being developed by Dr. Coe, of Portland.

Portland, March 1.

BRITISH COLUMBIA.

The following are the shipments and smelter receipts in southeastern British Columbia districts for the week ending Feb. 23: East of Columbia river, 2,146; Rossland, 4,780; and Boundary, 12,725 tons of ore. The smelter receipts were: Grand Forks, 6,287; Boundary Falls, 2,584; Greenwood, 2,280; Trail, 4,136; Nelson, 399; Northport, 2,835; and Marysville, 600 tons. Total, 19,121 tons for the week.——The Queen Victoria mine, just west of Nelson, recently purchased by James Cronin and associates, shipped its first lot of ore this afternoon to the Trail smelter.——The shipments from the Rossland mines for the same week were: Centre Star, 1,410; Le Roi, 3,150, and Le Roi No. 2, 510. Total, 5,070 tons of ore.——The new conveyor and large rock breaker at the Centre Star have been started. The breaker has a capacity of 1,000 tons per 10 hr., and the conveying plant will carry the ore from the mouth of the shaft to the ore bunkers.——The supply of coal, coke and cars is increasing, and it is expected that but little more trouble will be experienced.——Slocan operators and miners are rejoicing over the news that the duty on zinc has been abolished by the U. S. Government, which means increased activity at all the zinc mines of that district. The Lucky Jim and Slocan Star properties will be big producers of zinc.



The Boundary District of British Columbia.

MEXICO.

GUANAJUATO.

(Special Correspondence).—The Real del Monte y Pachuca Co. of Pachuca will equip both their large cyanide all-slime plants with Butters filters. These cyanide plants are to be increased in size as soon as the first section is started, and any increase of slime is to be treated by the same filter.——Mr. Pattinson is considering the installation of a cyanide plant for El Bote mine near Zacatecas.——A plant is contemplated for treating the low-grade ores (under $40) of the Valenciana mine near Cañitas, Zacatecas.——The grading for the extension of the railroad from Marfil to Guanajuato is almost finished, and the laying of rails will begin soon. The proposed belt-line railroad to reach all the mines of the district will soon be begun and will, when completed, largely decrease mining and milling costs in the camp.——A large mill and cyanide plant is to be built at La Luz mine, about 9 km. from Guanajuato.

Guanajuato, Feb. 23.

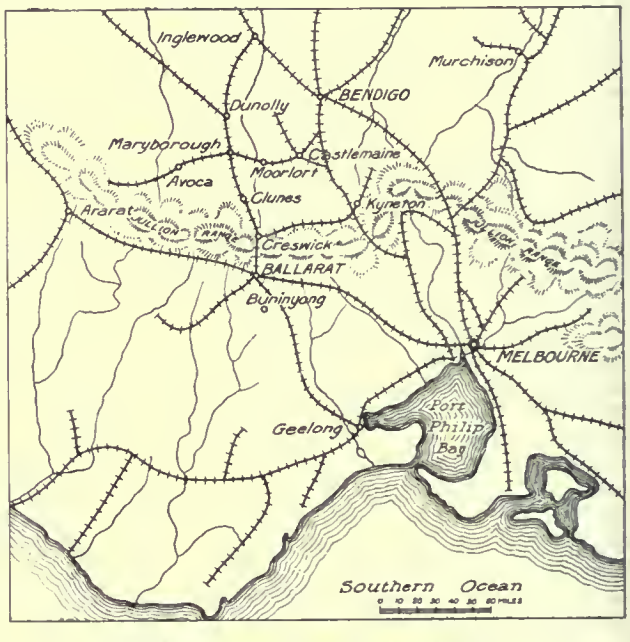
Special Correspondence.

London.

An Interesting Question.—Results at Dolcoath.—A New Shaft.—Cornish Enterprise in the Straits.—Gold Output of New Zealand.—The Deep Leads.—Depreciation in Rand Stocks.—Penn-Wyoming Co.—Good News From El Oro.

In the absence of a more thrilling topic, "One mine, one manager" is a proposal which has been agitating the public mind in Cornwall for some weeks past. The question is raised periodically, this time in consequence of the directors of Grenville United and Great Condurrow mines advertising for a manager for each of these companies, in the place of Mr. James Negus, who has been superintending both properties. From one point of view the mining industry in the County generally should, within the limits of a man's time and opportunity, benefit by such experience and ability as for example may be attained by a manager like, let us say, Mr. Arthur Thomas of Dolcoath. It is a proverb in Cornwall that "a good bal makes a good captain." In the case cited there must be some truth in the old saying, as the mine in question has afforded a sphere of activity greatly calculated to evolve what we know as a first-class expert in tin mining. That being so, it seems only fair that the stockholders in the particular mine should have a prescriptive right to the special services of the man in whose making their property has played a predominant part. Although this point of view may be readily conceded, it is argued by those who have at heart the prosperity of the County as a whole that a manager of recognized standing should not be the exclusive monopoly of a particular mine. In this relation it is pointed out that in Africa and America one expert is placed at the head of a series of mines—Mr. Harry T. Johns on the Rand, for instance. Equally it is held that men like the manager of Dolcoath and Mr. William Thomas of Botallack should not be confined to single propositions. It would not be to the interests of the industry to restrict their activities in such a way. For the present it would seem that Grenville United Co. has adopted the "one mine, one manager" principle, as the directors have appointed Mr. Frank Williams (assistant manager of West Kitty, St. Agnes) exclusively as their manager in the place of Mr. James Negus, who held other appointments as well. Mr. Williams, who is the son of the manager of West Kitty, had, it is said, a brilliant career at the Redruth School of Mines, and is quite a young man. Another new appointment is that of Capt. B. Nicholas as manager of Parbola, Gwinear. Capt. Nicholas is spoken of as having gained his early mining experience in the Levant mine, and secured brilliant success in science examinations, geology and kindred subjects being his favorite studies. For some years he held a responsible position on the Rand, and afterwards went to Brazil and Italy. Three years ago he was appointed agent at Dolcoath mine, on the retirement of Capt. Tamblyn, and has devoted most of his time to the working of the western part of the mine.

At Dolcoath, the bottom of the mine has grown so rich that the sinking of Williams' shaft is to be resumed as soon as the directors can arrange terms with the new 'lords'; and when the new shaft is down, a more rapid and economical method of working will be adopted. The new shaft will strike the lode 500 fathoms deep. A net profit of £41,757 was made by the mine in the second half of last year, which compares with £40,166 in the first half and £22,386 in the corresponding period of 1905. The dividend, at the rate of 20% per annum, compares with 15% for the preceding half and 7½% for the corresponding period, and the total for the year is 17½% against 6¼% in 1905. The rise in the price of tin more than counterbalanced the decline in the quality of the ore raised. The question of workmen's dwellings is said to be seriously engaging the attention of the executives of Botallack. It is proposed to erect a colony of workmen's cottages and let them to the miners at a reasonable rent. A new shaft is to be sunk immediately. It will take three years. Meanwhile three old shafts are being cut down and timbered, and as soon as the engines are working, the mine is expected to make returns. It is hoped to start the Great Condurrow pumping engine during the present month. According to the *Western Morning News*, the outlook in the Breage district is rapidly improving. Old miners describe Godolphin and Tregoning hills in Breage, as "houses of tin." After prospecting there for several weeks a party of miners has discovered a lode in the old Wheal Lemon



Map of Part of Victoria, Australia.

sett, and in all probability operations will be conducted there on more extended lines in the near future. Old Great Work mine has been acquired from the licensees (South West Cornwall Mines Ltd.) by a party of London capitalists. It is proposed to install an electrical plant and machinery on a large scale, and the property is to be thoroughly developed. Electricity, it is stated, will be generated at old Great Work for working the machinery and appliances on order for the adjoining mines, Lady Gwendoline and Wheal Reath, where the South-West Cornwall Mines have been operating for several months. Old Great Work is regarded as one of the best tin mines in the West, and it has a fine history. It is an extensive sett, and was first opened over 200 years ago. There are a large number of shafts, the principal ones being Great Fortune, 170 fathoms; Deer Park, 200; and Leeds, 166. The known tin lodes number about 13. The mother lode proceeds east and west, dips north one foot to the fathom, averages five feet in width, and gave a high percentage of tin to the ton. Wolfram exists in large quantities in some parts.

It is reported that a new Straits company, Tekka (Ltd.), is being formed under Cornish auspices, James Wickett, J. H. Bain, A. Lanyon, G. B. Pearce, and F. D. Osborne being directors. The company will acquire a property in the Kinta district of Perak, in the Federated Malay States, and work it on similar lines to those which have been so successful on the Gopeng prop-

erties. The capital of the new company will be £90,000 in 90,000 shares, and it is proposed to issue 70,000. The price to be paid is £30,000, leaving £40,000 for working capital, and of the present issue of 55,000 shares Messrs. Osborne and Chappell, who are the vendors, and the managers of the most successful of the Straits mines, have agreed to apply for 40,000 on behalf of themselves and their friends. All the shares have been applied for, the capital being, in fact, over-subscribed.

New Zealand statistics for the year 1906 show that the gold returns from the Colony are higher during the period under review than for the past 35 years. Since the industry was started on a sound basis in the year 1857 there have been prodnced no fewer than 17,708,978 oz. valued at £69,567,802. In 1906 the yield amounted to 562,351 oz. bullion to the value of £2,337,218, an improvement over 1905 of 41,839 oz. or £243,133. The list of dividend paying mines on the London market is a small one, headed by the Waihi, the distribution to stockholders in 1906 having reached a total of 70% on an issued capital of nearly half a million sterling.

The usual pumping statistics are fortheoming from Loddon Valley (deep leads) for December. The main pumping plant ran 30 days 19¾ hours during the month and raised 99,113,440 gal., consuming 1,000 tons of firewood. The Keystone plant ran nearly full time and pumped 58,678,704 gal. for the month, the consumption of firewood being 615 tons. Regarding the developments, later news by cable is to the effect that the wash has been entered in the cross-cut west of the No. 3 rise from south drift No. 3. A section 4½ ft. by 2 ft. by 6 in. was sampled and gave 3 dwt. 3 gr., which is described as a splendid sample and highly payable. The stock moved up on this announcement.

Notwithstanding the record for dividends created by Rand mining companies in 1906 (the total having been £5,565,970), the leading London companies investing in the stock of these mines continue the writing down process in consequence of deprecintion in prices during the year. The South African Gold Trust Co. has deducted no less a sum than £364,456 from the value of Transvaal stock, followed by the Exploration Co. with £98,726. It seems a paradox that, while the mining companies' dividends increase, the profits of the investing companies should decrease, but it is only sound policy to make good the loss of capital in the manner described.

A circular has been issued by Penn-Wyoming Copper, which reports that the company will shortly be in a position to put into operation the re-modeled smelter and new concentrating plant, which will treat the quantity of copper ore accumulated from the company's operations during the past year, as well as the ore coming from other mines throughout the Encampment district. The new mill is completed, with the exception of some lighter machinery, belting, and shafting. The heavy machinery, which includes boilers, crushers, rolls, and mills, is installed. The balance of the machinery and other material to finish it is either in the cars at Wolcott Junction or in the course of being hauled between Wolcott and Encampment. The Westinghouse turbine engine has arrived at Wolcott. This will give the company a minimum of 1,250 h.p. at their smelting works. Dealing with inquiries from stockholders as to the earning power of the company, and what dividend will be paid when smelting operations are resumed, the company states: The net profit on the last 90 days during which the old mill was running 12 months ago was $175,786. At the present price of copper this would have been a net profit of $392,054 on a 90 days run only. The smelting and reduction works as re-modeled and rebuilt can handle three times as much ore as the old works, and, when in full operation, there will be a saving of from $500 to $800 per day on rail transportation; in addition to which, as the company will own the railroad itself, the profits derived from transportation will go to the company's treasury.

Stockholders in El Oro (Mexico) are pleased with the latest news. In a general summary of the development work for the past six months, Mr. Raymond, the general manager, reports: "1,000-ft. level—the drift south on the branch veins, first encountered in the cross-cut from the shaft on the hanging-wall side of the San Rafael vein, has been advanced a distance of 125 ft. Within this drift two veins have now been found, each varying from 6 to 15 in. in width, and have been exposed for the entire length. They present a very favorable appearance, and have shown an average value of $11 per ton, this value increasing at times to $20 and $40 per ton whenever these two veins come together. Going north from the shaft, we have encountered, at a distance of 230 ft., what appears like the commencement of an orebody, which at present shows a width of about 6 ft., sampling from $3.50 to $5 in gold." In a cable dated February 7, Mr. Raymond states: "North drift on the main San Rafael vein in the 1,000-ft. level shows considerable improvement, and for the first time exposes sulphide ore; samples from the face yield from $3 to $10 per ton." Mr. Raymond's report also states that in the middle and southern sections the orebodies already exposed have been shown to be of greater length, and have been proved to a further depth than stated in the last annual report.

Johannesburg, Transvaal.

Stoping by Hand.—A New Drill for Narrow Stopes.—Political Events.—Unemployed Labor.—Gold Mining Details.

In those mines of the Rand where the reefs are narrow, from one to six inches wide, narrow stoping is of the utmost importance. It is almost impossible to carry the stopes from 24 to 30 in. with the rock-drills supplied by the standard makers, so that hand-labor becomes necessary. Working such narrow reefs with hand-labor requires a large number of hammers to keep a mill supplied with ore. In a narrow stope one coolie or Kaffir will break about 0.5 to 0.6 ton per shift. Of this about 20% is sorted out as waste, leaving abont 0.44 ton per man per shift for the mill. As long as hand-labor is depended on to keep the mines going, the demand for Kaffir or coolie labor will be excessive. On accounnt of the agitation against Chinese and the scarcity of Kaffir labor, much attention has been given to the perfecting of the Gordon drill, a machine designed for narrow stoping, from 24 to 30 inches. Some interesting tests have been made on the Robinson mine, and it was found that one white miner superintending four drills broke as much rock in a stope as 25 hammer-Kaffirs broke. The white man was assisted by five Kaffirs.

On a small scale this drill has proved so successful that two of the leading mining houses have ordered several hundred of these machines. Politicians have made a great deal out of this fact, and declare that the Gordon drill will do away with so many hammer-hands that it will be unnecessary to employ Chinese at all. It is too soon to state what effect this drill will have on the economic situation. Should it solve the labor question, and do away with the necessity of Chinese labor, South Africa will owe it a debt of gratitude. It is improbable that the stoping costs will be less by this drill than by hand-labor. A considerable improvement in the working conditions will be brought about, for by the use of water in drilling no dust is formed when using the Gordon

drill. A company has been floated called Gordon Drill Ltd., and it is stated that the machines will be made by the Ingersoll Rand Company.

Quite a blow to the prospects of the Progressive party was given last week by the action of Sir Richard Solomon in throwing in his lot with the Nationalist party, which is working with Het Volk, the Boer party. It is stated that Sir Richard will probably be the first premier of the Transvaal, and that, if he succeeds, the Het Volk party will have a majority in the first parliament. This party is not sympathetic to the mining industry. They seem to think that the mines can stand any amount of taxation, both direct and indirect, and that somehow or other, the mines can be run without so much unskilled labor. None of the Het Volk party are practical mining men, and consequently know little about our problems. In the future the mining industry must have the most sympathetic legislation, and every help. The 'deep-deep' level mines will have all they can do to pay dividends, without being hampered with unjust taxation.

The mining correspondent of the *Rand Daily Mail*, in a recent letter from Australia, stated there were a number of openings for men on the Broken Hill Proprietary, and advised men out of work in Johannesburg to make for Australia. This letter created a lot of discussion, but it is improbable that many of the unemployed will leave the Rand. The efficient men are hanging on, realizing that there will be a big improvement here, if the political campaign ends the right way. The inefficient unemployed would just as soon starve on the Rand as anywhere else.

A table published a day or so ago shows that the average value per ton milled in December was 33.85 shillings. The highest yield per ton milled on the Rand was 63.83 on the Bonanza, and the two lowest mines were the Orion with 19.9s., and the Glencairn Main Reef with 22.36s. per ton. During December the average amount of waste rock sorted out was 15.84 per cent.

Butte, Montana.

The February Output.—Production Hindered.—The Labor Situation.—Serious Condition.—Preparations for a Strike.—Discovery in the Berlin.—The Butte & Continental.—New Incorporations.

The mines of Butte yielded 258,300 tons of ore in February, and from that 19,682,460 lb. copper were produced. The shortage of coal and cars, and the extreme cold weather during the fore part of the month, were responsible for the small production. The production of the different companies was as follows:

Company.	Tons of ore.	Pounds of copper.
Boston & Montana	66,500	5,120,500
Anaconda	72,800	5,460,000
Butte & Boston	11,200	761,600
Washoe	10,500	721,500
Parrot	6,160	369,600
Trenton	11,900	725,900
North Butte	25,200	2,646,000
Coalition	22,960	1,722,000
Original	15,960	973,560
East Butte	2,800	221,000
Pittsburgh & Montana	4,480	380,800
La France	5,040	378,000
Miscellaneous	2,800	196,000
Total	258,300	19,682,460

The unsettled labor situation in Butte has had a bad effect on mining conditions lately, but there is no probability of any serious trouble between the miners and the mining companies. Although the miners voted to raise wages from $3.75 to $4 per day, there is a unanimous feeling among them that there will be no strike even if the companies will not grant the increase asked for. The miners say their vote for a raise was merely a request, and that they were forced into the action by the constantly renewed demands for more wages by the smaller labor unions, whose demands have always been granted and the money paid them has added to the increased cost of living in Butte, from which the miners, being the largest portion of the population, have suffered most. House rent and all necessaries of life have been advanced 30 to 50% in Butte in two or three years, all due to the fact that landlords, merchants, and dealers of all classes have gradually advanced their prices to meet the demands of labor. Before the miners voted on the increase, they were informed that it would not be granted. The mining companies, while believing there will be no strike on the first of May, the time set for the new wage scale to take effect, are taking no chances, and they have suspended all construction and development work at the mines and smelters, and fully 3,000 men engaged in that class of work have been paid off and discharged. All the mines are being put in condition for a long shut-down, should one become necessary, but until a suspension is forced the mining companies will continue the extraction of ore from the ground blocked out. The development work in all of the large mines is from two to three years in advance of actual mining and in some of the properties of the Amalgamated, North Butte, and Butte Coalition there are ore reserves blocked out upon which mining can be done for five years or more. There will, therefore, be no diminution of the output unless a complete shut-down should be forced upon the operators. All shaft-sinking on the Badger State, Greenleaf, Minnie Healey, Corra, Pennsylvania, Anaconda, High Ore, Parrot, Gagnon, Little Mina, Berlin, and all other development work in the Amalgamated mines has been stopped. So has the work of enlarging the smelters at Great Falls and Anaconda. All of the large mining companies have entered an agreement not to pay the increased wages demanded. The opposition is not so much to the miners as it is against the whole tendency of labor in Butte. The city and the district have always been dominated by labor unions, and employers believe the situation has reached a stage of intolerance that must be met by united action, and so, although they sympathize with the miners, the merchants and mining interests have united in a protest which is likely to clear the labor atmosphere of Butte before a final adjustment of the wage question is reached. The miners, whose regular scale for underground work is $3,50, although the mining companies have voluntarily paid $3.75, are comparatively the poorest paid class of labor in Butte. Hod-carriers get $5.50 per day and common street laborers $3, while plumbers get $7 and have in force a rule that no other plumbers can come to Butte, no one may learn the trade in Butte, and no one can employ a plumber except through a master plumber, who charges the builder or employer $12 per day for the plumber's services. Printers get $6 per day for setting 30,000 ems, and when the pressmen demanded similar wages for their two or three hours of labor the newspapers balked and the four dailies suspended publication. For three weeks Butte and Anaconda, with a combined population of 90,000, have been without newspapers. The labor situation in Butte must be reconstructed before the mines will resume full operation again, and before the newspapers will issue another edition. National labor organizers, who have been sent to Butte to investigate the situation, have expressed astonishment at the tolerance of conditions by employers. They say a general labor strike in Butte is not possible, as the strikers would have little sympathy from the outside.

The labor troubles have no bearing or effect on the new companies that are engaged in developing numerous properties in all parts of the district, because, in order to

get the best and most competent miners, these concerns have always paid more than the regulation scale of wages. The development work of such companies as the East Butte, Butte & London, Butte Exploration, Amazon-Butte, Ida Montana, Butte Copper, Butte-Milwaukee, Butte & Superior, Farrell, Alliance, La France, Davis-Daly, Butte Central & Boston, Butte & Bacorn, Butte & Summit Valley, Bullwhacker, Pittsburg & Montana, and Reins Copper companies will not be interrupted or interfered with. Good reports of progress and encouraging development comes from nearly all of the new properties.

The strike recently made in the Berlin claim by the North Butte Co. is one of the most important ever made in the district. Driving on the vein proves that the orebody continues in extent and richness. The vein is from 28 to 30 ft. wide, all of high-grade ore, and has six to seven feet of copper glance that assays 50% copper. The vein runs northwest and southeast, and will probably be found in the ground of the Butte & London Co. and other properties east of the Berlin.——The Butte Copper Exploration Co., which is developing the Six O'Clock group of mines east of the Butte & London, has penetrated a

Montana.

vein in the cross-cut north from the 1,000-ft. level. The cross-cut passed through a large fault and then entered a vein. No big body of ore has been found, but driving is being done on a small seam of ore and the indications are taken to be encouraging. It may be necessary to sink a few hundred feet deeper, but the officials in Butte and the miners employed in the cross-cut believe ore will be found at the present depth.

Good progress is being made in the work on the Ophir mine by the Butte Central & Boston Copper corporation. The shaft will be enlarged from the 500-ft. level to the surface and the work will take probably three months. Meantime no stoping will be done, but development work will be pushed. Some fine orebodies have been opened.——The Butte & Continental Mining Co. has ordered a lot of new machinery for a complete and modern surface plant, which will be installed on its claims east of the Butte district, on top of the continental divide. Two of the claims are developed, and Mr. Tomek, the manager, says the mines can be made to pay for all development work in a few months after work is resumed.——The Michigan Mining Co., with a capital stock of $1,000,000, has been incorporated in Butte. The directors are J. H. Vivian, James H. Rowe, James Higgins, James E. Higgins, and J. E. Corette. —— The Pittsburgh Gold & Tungsten Mining Co., which is developing some gold and tungsten deposits near Gardiner, Mont., has increased its capital stock from $100,000 to $1,000,000, and has moved its principal office from Gardiner to Butte. The directors are Harry Bush and B. F. Shearer, of Pittsburg, and E. A. Downs, of Livingston, Montana.

Denver, Colorado.

Resumption of Work in Old Mines.—Varied Resourcefulness of Colorado Mining Districts.—The Legislature and Its Foolishness.—A Tunneling Machine.

The re-opening of the old workings of the Millington mine near Georgetown stimulates a moment's reflection on the permanence of the various mining districts of Colorado. It is natural to think of mining as a temporary industry; ore deposits, after being worked for a longer or shorter period, become so exhausted or impoverished in value as to be no longer profitable, and are abandoned. But in many cases the operations may extend over a long period of time, as certain Spanish mines whose honorable history covers more than one century. Districts are even less temporary in their nature, for the stimulus of the propinquity of producing mines makes possible exploration that frequently opens up larger deposits than those originally discovered, which, with the cheaper freight, lower working and treatment costs that result from the bigger scale of working, and better knowledge of the peculiar problems of the districts, stretch out a span of life so that it extends in uninterrupted security long after the original 'boom' has become little more than a memory. Such, for example, is Leadville, which for forty years has steadily persisted, changing completely in the meanwhile its character as a mining district, so that minerals once regarded as decidedly detrimental are now a source of profit, and which at the end of its quadrennial period seems to have an assured future for many years to come. In like degree the same is true of the other mining districts of the State. Cripple Creek, after touching the crest of its wave of prosperity, apparently has settled down to a steady production. Not to stretch out the list too far, we may sum up by saying that the mineral industry of Colorado is not fated to disappear, but to renew itself periodically, changing its form, but maintaining its volume.

The action of the lower House of the present legislature of Colorado, now sitting at Denver, in adjourning for a greater period of time than the Constitution permits, seems extremely likely to affect the validity of the laws passed during this session. Whether the laws passed may be actually unconstitutional or not, opportunity will be afforded for tiresome and expensive legal battles, which, in the end, are likely to result in depleting the public purse, while those whom the law seeks to restrain continue the even tenor of their way. Undoubtedly this will be true of the corporation publicity law, should it finally secure passage. It was to be expected that those affected by it would make every effort to escape complying with its provisions, but the action of the legislature is well calculated to make such escape easy. The patience of the public with the men it designates to frame its laws is truly remarkable.

The owners of the rights of the Karns tunnel-driving machine are making efforts to have it adopted to drive the new drainage adit at Cripple Creek. The claim is made that with it the adit can be driven in one-third the time and at one-half the cost of the same work when done with rock-drills. The machine is somewhat similar to types that have previously been tried in tunnel work, consisting of a wheel of the requisite diameter, carrying revolving discs. Whether it will be given a trial remains to be seen. The inadvisability of further complicating the unforeseen in engineering work by using new and improved types of machinery usually appeals so

strongly to the engineer in charge of important works that he is likely to turn a deaf ear to the enthusiastic predictions of inventors. Ostwald has said that the possession of accurate scientific knowledge serves to turn its possessor into a true prophet, who can correctly prophesy future happenings. But, unfortunately, at best our stock of knowledge is painfully limited, and the clear-headed and conscientious engineer generally prefers to limit his prophesying to its least possible dimensions.

Salt Lake, Utah.

The Cactus to Pay a Dividend.—Consolidation at Stockton.—Shipments from Tintic.—Output of Park City.—The Ontario Adit.

The Newhouse Mines & Smelters Co., owner of the Cactus mine in Beaver county, will pay dividends before the close of the present year. This announcement has been made by Samuel Newhouse, president of the corporation. On the 600-ft. level of the mine the ore-body has been opened to a width of 246 ft. While the ore is largely a milling product, there are extensive deposits of high-grade ore. Shipments of the latter, averaging better than 15% copper, are being made. It is estimated that the March earnings will net about $225,000.——The Frisco Contact mine, in Beaver county, is still inactive. The management complains that it has been impossible to get fuel.——Samuel Newhouse, D. C. Jackling, and Charles W. Whitley have purchased a large stock interest in the Emma Copper Co., with properties at Alta. The Alta Coalition Copper Co. has been formed to develop a property near Alta. The officers are: F. R. Snow, president; B. F. Grant, vice-president, and N. Y. Stringham, of Salt Lake, treasurer. It is expected that the contract for the proposed mill for the Albion mine at Alta will be let about April 1.

It has been learned from an authoritative source that F. Augustus Heinze has secured options on several mines in Stockton and that he is effecting a consolidation scheme. It is believed that the Honerine mine and drainage adit is included in the list. Although nothing official can be obtained at this time, it is fairly certain that the Bingham Con. Mining & Smelting Co., will move its Bingham Junction smelter to Tooele county, and it is just possible that the new plant will be erected somewhere near the mouth of the Honerine adit, from which an abundant water supply could be obtained, in addition to its convenience as an avenue through which the ores of nearly all the principal mines of the district will come. The management of the New Stockton Mining Co. is figuring on the installation of an aerial tramway and the construction of a new mill. The property is equipped with a small plant, but not of the size sufficient to much more than meet operating expenses.

The ore shipments from the Tintic mining district last week amounted to 151 carloads, the shipping properties and respective amounts being: Ajax, 1; Brooklyn, 2; Bullion Beck, 9; Beck Tunnel, 8; Carisa, 2; Centennial Eureka, 57; Eureka Hill, 12; Eagle & Blue Bell, 6; Swansea, 4; Tintic Iron, 6; Uncle Sam, 1; Victoria, 6; Yankee Con., 2 carloads.——The Lower Mammoth Mining Co. has its two new electric hoists in service and is marketing ore at the rate of 100 tons per day.——Shareholders of the Bullock Mining Co., operating in the Tintic district and with offices at Provo, has elected the following officers: B. H. Bullock, president; J. I. Bullock, vice-president; who, with M. M. Kellog, W. F. Giles, and Thomas Boardman are directors.

The ore shipments from Park City last week aggregated about 1,650 tons, the same coming from the following properties: Daly-Judge, 774; Little Bell, 11; Daly, 77; Silver King, 605; Daly-West, 510; Ontario, 98 tons. The development of the Naildriver property continues vigorously. Work at the present time is being directed on the 200-ft. cross-cut from the 850-ft. level. The Ontario drainage adit is cleared as far as No. 2 Ontario shaft. The latter is being repaired and put in condition for operation. The adit has been closed for over two years on account of caves.

Cripple Creek, Colorado.

El Paso Surrenders Drilling Equipment to Tunnel Co.—Drainage Adit to be Pushed.—Another Cyanide Mill.—British-American Co.—The Christmas Lease.

A 12-drill Norwalk compressor and a 175-h.p. electric motor ordered some months back for the El Paso mine are to be turned over, when received, to the Drainage Tunnel Co. for operating the drills on the big bore. By accepting this offer of the El Paso Co. work can be commenced several months sooner than would otherwise be the case. The cost of the machinery, which should arrive in the district within the next few days, will be borne by the tunnel company. Grading has already commenced for the various buildings that will be required at the portal of the adit. A first request for 10% of the amount subscribed by the various mining companies has been made and has resulted so far in the receipt of $22,000.

Grading has commeneed for the new cyanide mill on the W. P. H. property situated on Ironclad hill. A. B. Whitmore is manager of the leasing company that is operating the W. P. H. mine. The plant is being erected under the direction of Engineer Groch and should be ready for operations by May 1.——It is stated that the large cyanide mill of the Cripple Creek Homestake Mining & Reduction Co. will be put in operation next week at a daily capacity of not less than 100 tons. The Phœnix Mining & Leasing Co., composed principally of the Homestake Co.'s directorate, will operate the plant, this decision being brought about by their successful treatment of ore averaging $4 or $5 per ton in the small Homestake mill. The ore will be obtained principally from the Ironclad and Magna Charta claims adjoining the mill.

The British-American Mining Co., Ltd., that is, Becker, Travell & Co., operating the South Dante, shipped on an average a car of ore per day during the month of February. The bulk ore has been running in the neighborhood of $20, and the screening $30 per ton, but much better returns are expected during the present month, as some high-grade ore has been encountered during the last few days, which should make the screening run several ounces in gold. Samples from this new strike show rusty gold in several places, and assay many hundred dollars per ton.——The Christmas mine, situated between the Golden Cycle and the Vindicator mines on Bull hill, shipped 500 tons of ore during the month of February, averaging $25 per ton. The ore is being mined on the seventh, eighth, ninth, and tenth levels. Becker, Travell & Co. are operating this property under lease, which is now looking better than it has for several months.

McLeod, Lewis & Jones, lessees on the Proper claim of the Stratton Estate, shipped a car of ore last week, which gave returns of $50 per ton. A car of ore per week is being shipped from this lease, the ore being obtained at a depth of 100 feet.

The milling of low-grade ores is becoming such an important problem in this camp, that much experimental work is being done by the local custom-mills. Efforts have been confined almost exclusively to development of the cyanide process in a form which will render roasting unnecessary, but it is still a grave question whether the low-grade sulphide ores can ever be treated successfully by this process.

Cobalt, Ontario.

Growth of Business.— Extension of the District.— Working Under the Lake.— Systematic Prospecting.— The Green-Meehan.— Some Rich Ore.— Right-of-Way Co.— New Camp in Northern Ontario. Larder Lake.—Another Gold Find by Prospectors.

The towns of Cobalt, Latchford, and Haileybury are the chief distributing points for the mail-matter coming into this mining camp. The growing importance of the camp, and the volume of buiness done within its borders, may be fairly evidenced by the postal returns of these three postoffices. At Cobalt, 2,000 letters are received daily, and the revenue of this little office amounts to $15,000 or $18,000 per year. On Christmas Day, 22 bags of mail-matter were assorted, and it took the postmaster and five assistants nearly five hours of steady work to accomplish this.

New discoveries are reported from all quarters, and the mining area has been enlarged for a distance of from 25 to 50 miles in all directions from the town of Cobalt. While in these extensions the surface values may not prove to be so high as in the small six miles square of the camp proper, they are not wanting men who declare that it will be in some of the extensions that mining will be carried on, say, 25 years hence. Charles Giffard at the Victoria struck native silver the other day in his main shaft at a depth of 35 ft. The surface ore ran very low in silver. His property is in the fifth concession of Coleman and adjoins the Colonial.—— At the Cobalt Chief and the Dufferin, fair discoveries were made last week. Supt. Fee, of the Cobalt Chief, has installed one of the best plants in the Portage Bay district, and has found small flakes of silver in the shaft being sunk on the main vein, which on the surface was a small streak a couple of inches wide.——Supt. Shillington of the Dufferin, is installing a plant from the Rand-Jenkes Company.

The mining rights of Cobalt lake were recently sold by the Ontario Government for over one million dollars. Many mining men in the camp looked unfavorably on this proposition in its early history, but during the past two weeks some valuable finds have been made on the 33-ft. shore-line, which the company owns, along with the right to mine beneath the lake. One of these is a 14-in. vein that was located on February 20, a mass of niccolite and cobalt undoubtedly carrying silver values, was uncovered.

Vein No. 4, on the Lake property, has an average width of 12 in., it is a calcite vein with surface assays as high as 9,875 oz. silver per ton. It is on this vein that the main shaft is being sunk. Another vein known as No. 5 had a surface width of six inches, and carrys 1,000 oz. silver per ton. A first-class plant has been ordered from the Rand-Jenkes Co., consisting of two 100 h.p. boilers, one 15-drill compressor, steam-hoists, etc. The Lake is being surveyed in blocks, one chain square, and pegs are being driven in the ice at the four corners of each block. The diamond-drill is being used to test the depth to bedrock at each corner of these blocks or squares. A chart will be made and the different depths of each test recorded so that the management will be enabled to estimate the different depths to be attained in the different shafts that are being sunk, so as to ensure them against any trouble that might be caused by water leaking through to their cross-cuts beneath the Lake.

A large office has been erected on the shore lying opposite the town of Cobalt, and a sleeping camp to accommodate 85 men will be built immediately. At present a gang of 65 men is kept constantly at work stripping the 33-ft. shore-line and sinking five shafts.

At the Red Rock, Green-Meehan, and Hunter properties active developments are taking place, and at the two former, first-class plants have been ordered and are partially installed. At the Green-Meehan two 100-h.p. boilers are on the ground, the power-house is nearly completed, and accommodation will be forthcoming for 120 men within the next two weeks. This mine is not capitalized at $2,500,000 in one dollar shares as has erroneously been stated in some papers. The holding company has that capitalization, but the Green-Meehan mine was capitalized at $1,500,000. The stock has sold as high as $1.70. The present company took hold of the property in November, and has shipped two carloads of rich ore, and today has a third carload of 40 tons ready for shipment. On vein No. 1 a double-compartment shaft has been sunk 35 ft., and to this level the vein has maintained its surface width of six inches; the width of course varies in some places, narrowing to three inches. At the 35-ft. level a distinct and separate vein has been found in the shaft, the calcite carrying native silver. The work on No. 2 vein has been entirely an open-cut 80 ft. long and 25 ft. wide, and at the bottom of the cut the vein is 11 in. wide, carries over 1,000 oz. silver per ton, and is of solid metallic ore. The Keewatin wall-rock is heavily shot with leaf silver on either side for a distance of four or five feet, and this country-rock will run probably 400 oz. silver per ton, and will be treated by a concentrating plant not yet erected. There will be sufficient of this ore to keep such a plant constantly at work.

The sensational first shipment of the Right-of-Way Mining Co. netted $57,000, which has enabled this company to declare a dividend of 7% within three months of acquiring the property. The ore has simply been gouged out of their vein, which runs along the railway track, and has come from a hole a few feet long and a few feet deep.

Cobalt will have many rival camps this summer; they will be spread out all over northern New Ontario. A Larder boom has already started. This Larder gold camp as yet is only a possibility, and has been turned down by several mining engineers, but so was Cobalt in its early history. Although nearly 400 miles north of Toronto, hundreds of men are going in on snowshoes and dog-trains every week. On the northwest shore of this small lake a town of 1,100 inhabitants has sprung into existence. People are living in wagons, under wagons, and in tents, and a repetition of the Klondike boom is being experienced. There are three trails from different points along the T. & N. O. Railway into Larder. The shortest one is from Boston, and is only nine miles long, but it is said that owing to the bad hills there are more broken toboggans decorating the trees along the trail than are to be found on the other two. Englehart, a divisional point on the railway, 37 miles north of Cobalt, is recognized as the best starting point for Larder, and with a team and sleigh a return trip can be made from there in a day.

Some prospectors returning from a much more distant point, either in this Province or the neighboring Province of Quebec, have brought some magnificent gold samples. The exact location of this new find has not been made public, but there is no doubt the specimens come from above the height-of-land. The old prospector in charge of the party states that gold, silver, and copper-bearing quartz has been found in large veins, and that good gold and copper values are found in every foot of the shafts so far sunk, some of which are down to a depth of over fifty feet. Forty miles north of Larder, up the Montreal river, discoveries are also being announced, but as similar announcements were made at various times last summer, more definite information will have to be received before it will detract from the attractiveness of Cobalt itself.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE most common cause of earthquakes is either the formation of a great fissure, or else the re-adjustment of the walls of such a fissure.

THE Grand Cañon of the Colorado is 300 miles long and varies from 3,000 to 6,200 ft. in depth, forming the grandest natural geological section known.

THE term 'drift,' as used in geology, is a relic of an early and erroneous idea that the mantle of rock-rubbish which covers glaciated territory was due to overwhelming floods of water from the North.

THE hydrographic basin of the Mississippi river is bounded on the east and west by the Alleghany and the Rocky Mountains, and on the north by a low ridge running westerly from Lake Superior.

CLOTH SCREENS give a greater percentage of opening, and therefore a greater capacity, than punched plate. The percentage of opening is the ratio of the net area of the holes to the whole area of the screening surface.

THE TERM 'denudation' is used by geologists to express the general erosion which the earth-surface has suffered in geological times. The correlative of denudation is 'sedimentation,' and the amount of denudation is measured by the amount of stratified rocks.

IN choosing crushing machines, the points to be considered are first cost, weight, number of wearing parts, power, speed, and wear. At the same time the machine should be simple in construction, easy to erect and operate, and the wearing parts should be easily renewable.

THE deepest bore-hole in the world was bored in Silesia several years ago, to 6,700 ft. In the Transvaal John Schanke, an American contractor, put a hole down 6,340 ft. to cut the Main Reef; the core was two inches at the start and 1⅝ in. diam. at the bottom. A Sullivan Class P. machine was used.

THE Newhouse tunnel, at Idaho Springs, 37 miles west of Denver, and in the lower Clear Creek mining district, was driven a maximum distance of 267 ft. in one month. A total distance of 2,760 ft. was made from September 1899 to August 1900, at a total cost of $79,470, an average of $28 per foot.

A GOOD mixture for concrete is one part of cement, three parts sand, and five parts of crushed rock. The sand should be angular, and the grains irregular in shape, and the stone should be broken fragments and not smooth pebbles. Other proportions often used are: One, two, and four; and one, four, and seven parts.

THE transporting power of a current of water, or the weight of the largest fragment it can carry, varies as the sixth power of the velocity. That is, if a current of certain velocity will move a cubic inch of stone, when the velocity of the current is doubled, it will move a stone sixty-four times as large, and if the velocity were increased ten times, the transporting power would be increased 1,000,000 times.

A TYPICAL 'ESKER' is a long, sinuous ridge of coarse sand or gravel, sharp-crested, with steep slopes, and rarely over 50 ft. in height. It was deposited in the bed of an overloaded glacial stream, which flowed between the ice-walls, either in a tunnel beneath the ice, or more probably in a trench or cañon cut down from the surface of the glacier by bottom melting. 'Esker' is a term commonly used among geologists in Michigan.

LOESS, in the form of a brownish, soft, structureless earth, covers great areas of the Mississippi basin. These deposits are considered, in part at least, as wind-born dust. Some authorities maintain that the material may have been glacial in its origin, but that it may have been subsequently transported and deposited by eolian agencies. Of course, eolian deposits must contain no rock materials that wind is incompetent to carry.

THE method used at Tombstone for mining old stope-filling consists in driving a series of spiling-drifts through the loose material. Attempts to draw the filling failed, as the hanging wall slabbed off, which had the double effect of introducing waste into the ore and blocking the chutes with coarse material. Where the old stope was not over 10 ft. wide it was possible to drive along one wall, necessitating spiling only on one side and in the roof. Often when the old stope was wide, and the filling loose, spiling was necessary at the top and both sides, at the same time keeping narrow breast-boards securely in position.

DRUMLINS are hills composed of glacial till and having strikingly smooth, curving, convex outlines, quite unlike the irregular hummocky surfaces of morainic hills. They may be mammillary, but are usually either oval or elongated as ridges, always with the longer axis in the direction of the ice movement, and are therefore good indices of the direction of glacial flow. These hills are formed beneath the retreating border of the ice-sheet, along the zone where the ice became incompetent to carry its burden. They are sub-glacial heapings of the ground-moraine, comparable to the longitudinal sand-bars in the bed of a river. They are not a common phenomenon in glacial topography.

IF *A* locates a vein, the apex cropping out along the centre line of his claim; and if *B* locates a tunnel-site parallel with *A*'s claim, and cuts *A*'s vein in his tunnel, then, upon the assumption that *A*'s location is valid and prior in point of time to the location of the tunnel-site by *B*, the location of the latter cannot deprive *A* of any rights acquired by his prior mining location. The extent of *A*'s rights will necessarily depend upon the course of the apex of the vein through the location and its position with reference to the end or side lines of the claim. Prior to patent *B* might have a right of way for his tunnel through *A*'s claim, but could not assert any right to any veins which have their tops or apices within the mining location.

THE WORK on a mining claim must be performed annually regardless of the minority of the owner. If not performed, the claim becomes subject to re-location. The law makes no discrimination in favor of minors or other persons under disability, such as idiots, and persons of unsound mind, and in some States "married women." The fact that the owner was left penniless does not help the matter. The minor could have a guardian appointed, and this guardian could, under order of Court, either sell or mortgage the claim. The plea of poverty for non-performance of assessment work, would obviously be a popular one, but if maintainable by a minor would be available to adults, as the law is general in its operation. The fallacy of such a plea is obvious.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Cyanide Poisoning.

The Editor:

Sir—My experience with cyanide poisoning may be of interest to others.

We started our cyanide plant in May, 1903; I attended the solution and was in it a great deal. About August of that year my hands and wrists broke out with what appeared to be skin poisoning from a vegetable source, such as poison oak (*rhus toxicodendron*) or thunderwood (*rhus venenata*), of which there is an abundance here.

I tried all common remedies such as sugar of lead (lead acetate), zinc ointment, sugar of lead and laudanum, etc., with no results.

I consulted local physicians and had prescribed and tried 2% carbolic acid saturated with boric acid, aristol and laudanum in petroleum jelly.

It finally developed into an aggravated case of eczema.

Finally Dr. Peters of Birmingham, Ala., prescribed as follows:

Equal parts ung. ichthyol; ung. boric acid.

Apply locally and continually until cured.

Avoid wetting hands, as water of any kind tends to aggravate the trouble. This cured it in about six months. However, it comes back in spots whenever I get my hands in cyanide solution very much, and especially if I handle precipitate or zinc in the precipitation-boxes; also, the hot gases from our melting-furnace, which contain considerable sulphur, bring it back more quickly and persistently than any other thing.

In cold, harsh weather, it comes back more easily and is harder to cure than in warm weather, similar to chronic eczema.

I have been able to keep my hands fairly free from it, by using the above ointment, and I still attend the solutions.

A. P. KENNEDY.

Yates, Ala., February 16.

Copper in Del Norte County.

The Editor:

Sir—I read with much interest the letter from Mr. James W. Abbott, on the Greenwater district, published January 12, and also your editorial comments on the subject, particularly the one appearing February 16. The point that strikes me most forcibly in this connection is the inconsistency of mining investors—those to whom we must look for the development of our prospects into mines—in rushing into districts like the one under discussion, and 'passing up' others of much greater promise. Is it an illustration of flamboyant advertising, or merely another evidence that the American public likes to be buncoed? To illustrate, I will make a little comparison of the Greenwater district as described in your columns, and the Del Norte district. The Greenwater district has one copper belt in which there are a number of veins showing some gossan and copper oxides on and near the surface. There is little or no sulphide ore in sight, and the oxides are all low-grade; some may be sorted to 8%, and much of it to not over 3% copper. The Del Norte district has at least five distinct copper belts in different geological formations, and separated by spaces of from 5 to 15 miles. Three of these are being developed in a more or less desultory manner, the total amount of work done being somewhere near that done in the Greenwater district. The veins carry a cap of gossan, with here and there high-grade copper oxides showing on the surface. A few feet beneath the surface masses of oxides appear, running from 1 to 60% copper, and a short distance deeper we find sulphide orebodies, some of which will sort to 30%, and many of which will average from 5 to 15% copper. The name of Greenwater is on every tongue, while Del Norte is almost unknown.

JOHN B. PLATTS.

Crescent City, Cal., February 25.

Single-Stamp Mills.

The Editor:

Sir—Mr. J. W. Pinder's letter in your issue of February 2 is both timely and to the point, although in some details I disagree. It may be remembered that I recommended the single, or two-stamp mill, for milling where concentrating was the important consideration, both on account of the greater output for the power required and the less slime produced owing to the rapid discharge of crushed material. I am inclined to favor the wave motion over the plates, for the short interval between waves I believe an advantage. On a concentrating proposition this is of no consequence.

Many superintendents do not favor sizing before concentrating for the reason that it has been tried and failed. Theoretically the measure is correct, but often the machinery is unsuited and unfortunately most superintendents are restricted to the machinery in the mill with no option but to use what has been provided. I have tried sizing before concentrating, with two belt machines, but found that the machine taking the coarse material was overloaded and the machine taking the fine tended to float the slime, whereas, running with an average product the results were better, each machine did good work with much less water, and although some slime escaped, the results were better than sizing. Had this mill been equipped with proper concentrators for the work, I believe previous sizing would have been beneficial, for our trouble was entirely due to sliming of concentrate.

Some ores require inside amalgamation to obtain the best results, for I have tried both methods on the same ore, but there are cases where the results are better without inside plates, in which cases it were best to omit this treatment.

The idea of concentrating before amalgamation is good, depending upon the subsequent treatment of the concentrate. For example, if the concentrate goes to the smelter, well and good, but if to a chlorination, or cyanide plant, the large particles of gold that ordinary would be amalgamated may in this case of previous concentration be lost altogether, for both chlorine and cyanide of potassium dissolve coarse gold with difficulty.

The important point is, that every mill when erected, should be so constructed as to allow of some latitude in the arrangement of the machinery, in order that the management need not be tied down to one special method, whether good or bad, but permitted to arrange the mill according to the requirements of the ore.

ALGERNON DEL MAR.

Cobalt, Ontario, February 19.

RAILWAY ACCIDENTS for the three months ending June 30, 1906, show total casualties to passengers and employees on duty of 19,850. The corresponding total for the preceding quarter was 16,937. The number of passengers and employees killed in train accidents was 267, as against 194 reported in the preceding three months—an increase of 73. The total number of collisions and derailments in the quarter was 3,672 (1,891 collisions and 1,781 derailments), of which 269 collisions and 201 derailments affected passenger trains. The damage to cars, engines, and roadway by these accidents amounted to $2,932,760.

Steel Ore-Bin Construction.

Written for the MINING AND SCIENTIFIC PRESS
By W. R. CRANE.

Present practice in the Lake Superior region favors steel instead of wood in the construction of head-frames, shaft-houses, and ore-bins. The characteristic features of the shaft-houses of the copper country are inclined shafts, the tracks of which are supported upon bents and prolonged upward into massive structures standing some 100 to 125 ft. high, and containing, besides the head-gear, grizzly, sorting-floor and crushers, ore-bins, into which all copper ore of a size for stamping is stored, and from which it is drawn into railroad cars for shipment to the concentrating mills.

The enormous weight of these shaft-houses, when containing bins filled with the heavy copper ore, with their necessarily wide bases, places them in a class by themselves, permitting great height with high hoisting speeds and heavy and large-capacity crushers working far above the ground. Wood was formery employed in this construction; they were of great weight, somewhat difficult to construct, and especially liable to fires, therefore this practice has been largely discontinued, in favor of steel forms. During the winter of 1905–6, the large wooden house at shaft No. 3 of the Wolverine mine was destroyed by fire, and by the middle of the following July a steel structure occupied the same site and was in use, although not working at full capacity. See Fig. 1. Owing to the comparatively short time available for construction, in order that the capacity of the mine should not be seriously reduced, it was decided to erect a steel shaft-house similar to one at the Mohawk mine, under the same management. The great haste with which it was assembled did not permit of making any important alterations, the order being duplicated, except for some minor details, such as position of stairs, tramway, etc. The following notes and sketches descriptive of the ore-bins were taken by the writer and are given herewith, by the courtesy of Mr. Fred Smith, agent of the mine:

Fig. 1. Shaft No. 3, Wolverine Mine.

The bin was built upon the foundation of the former wooden structure, being a strongly built masonry wall enclosing a rectangular space, filled with broken stone, and capped with concrete. The concrete cap forms the bottom of the bin, which consequently is flat. The remaining portion of the bottom of the bin has a slope of 38°, which is the angle of repose of the ore, and also, as it happens, that of the dip of the lode. By choosing this angle instead of 45°, as is commonly used, greater capacity is possible with less height of bin.

The dimensions of the bin are as follows: Top and bottom, width about 38 and 19 ft., length 47 ft.; the sides adjacent to and opposite the inclined bottom are 11 and 28 ft. high, respectively. The inclined portion of the bottom is supported, as shown in Fig. 2, by 20-in. I-beams, connection being made between these horizontal beams and others supporting the sloping floor by means of gussets, which are re-inforced with angles. The floor planks are attached to 12-in. I-beams, cut in sections set between and attached to the gussets and 20-in. I-beams, as shown by angle connections; in a similar manner connection is made between the 12-in. I-beams and columns, except at *A*, where a continuous I-beam is used, the flanges being cut away to permit the web to be riveted to the side of the columns.

There are five rows of columns, composed of built up I-beams, which run parallel with the bin longitudinally; all of these, except the end ones, stand with the longer dimension of their section normal to the bin transversely, thus all of the outer columns have the same relative position with respect to the body of the bin. See Fig. 4. The object of this arrangement is to facilitate the placing of the lining planks of the bin, which are spiked to 4 by 10-in. timbers, bolted to the flanges of the columns. See *A*, Fig. 5. The corner posts on the shaft, or front, side of the bin are specially built angle-columns, consisting of two 15-in. plates, connected by a 6 by 6 in. angle and four 4 by 4 in. angles. See Fig. 4 and 5. The columns in the interior of the bin have 4 by 10 in. pine planks bolted between the legs of the angles, in order to protect them from the cutting action of the ore. The bracings of the columns within the bin are as simple and effective as possible, so as not to interfere with the movement of the broken ore.

The beams supporting the crushers are securely braced longitudinally by angles attached at points nearly opposite their ends and extending from column to column until the sides of the bin are reached, to which they are securely tied. The crushers are mounted directly upon channels, two to a side; their position with the enclosed timbers is shown in Fig. 5. These channels are supported on the shaft end by a 48-in. built-up I-beam (angles and plate), which is stiffened by angles spaced 24 in. apart. Upon the lower flange of this beam the channels are mounted, being connected with angles to the web or plate. This beam is in turn supported by three of the bin columns, and is tied to the adjacent ones on either end. A similar support is provided for the other end of the crusher-supports, except that in this case the channels rest upon the top of a 24-in. I-beam (composed of angles and plate). The three short columns supporting these beams, fore and aft, are braced by angles, as shown in Fig. 5.

The tops of the columns surrounding the bin are tied together with 12-in. channels, while those within the bin

are tied to one another and to the side and end columns by I-beams, which extend both longitudinally and transversely throughout the bin. The longitudinal members are the lower of the series, while those running transversely are the floor supports.

The method of attaching the longitudinally placed I-beams to the tops of the columns is shown in Fig. 5. They vary in size, from the front to the rear of the bin, to accommodate the load that they are to support, being made especially large at the rear, in order to support, with little vibration, the engine situated at that point on the crusher-floor above. These beams, taken in order from left to right (Fig. 2), are: 12, 12, 15, 19, and 12 in. respectively. The bin is braced on both front and rear sides by 4 by 4 in. angles, placed as shown in Fig. 3.

The head-frame is constructed directly upon the bin, the top of the latter being considered as the ground-level in the design of the former. The three middle columns, fore and aft, of the bin are continued upward, forming the main posts of the head-frame, which, together with the remaining columns, constitute the frame-work of the housing for the crushing and sorting floor. The three middle columns, which enter directly into the construction of the head-frame, are made sufficiently large to support the sheaves and resist the strains peculiar to hoisting, also wind pressure, all of which are in addition to the weight of the bin. No back-stays or braces are needed, as the height of the head-frame, thus considered, is moderate, and owing to the fact that the angles made by the hoisting rope with the horizontal on both shaft and hoist sides of the frame differ by only 10 or 15 degrees, the resultant of the hoisting forces falls well within its base.

The floor of the engine is re-inforced with concrete, which is tamped between the supporting I-beams, being held in place temporarily by sheets of corrugated iron bent in arches (convex side up), the ends resting on small intermediate I-beams set into the larger ones and spaced from 18 to 24 in. apart.

A small bin for 'mass' (chunks of native copper), 9 ft. long by 8 ft. wide and 9 ft. deep, is built into the upper right-hand corner on the side of the main bin, facing the shaft. See Fig. 2 and 4. This bin is connected with a discharge opening, in line with the others on the inclined bottom of the bin, by means of a semi-circular iron chute, furnished with an adjustable apron similar to the other gates. These adjustable chutes serve two purposes, namely, they act as gates to regulate the flow of ore or to stop it altogether, and when properly manipulated by the controlling levers, assist materially in filling and distributing the ore in the cars. When not loading into cars, the chutes are hung up by tying the free end of the controlling levers to the plank walk below. See Fig. 2.

Two 14 by 14 in. timbers are bolted together and set in the masonry bottom of the flat portion of the bin and are continued up to the crusher-floor, where they serve as a stool for an air-hammer used in reducing the large masses of rock and copper that are too hard and too securely bound together to be broken by hand. Directly back of the hammer is the opening into the mass-copper bin. All pieces of copper from fist size up are thrown into this bin and thence by the metal chute to a car for shipment di-

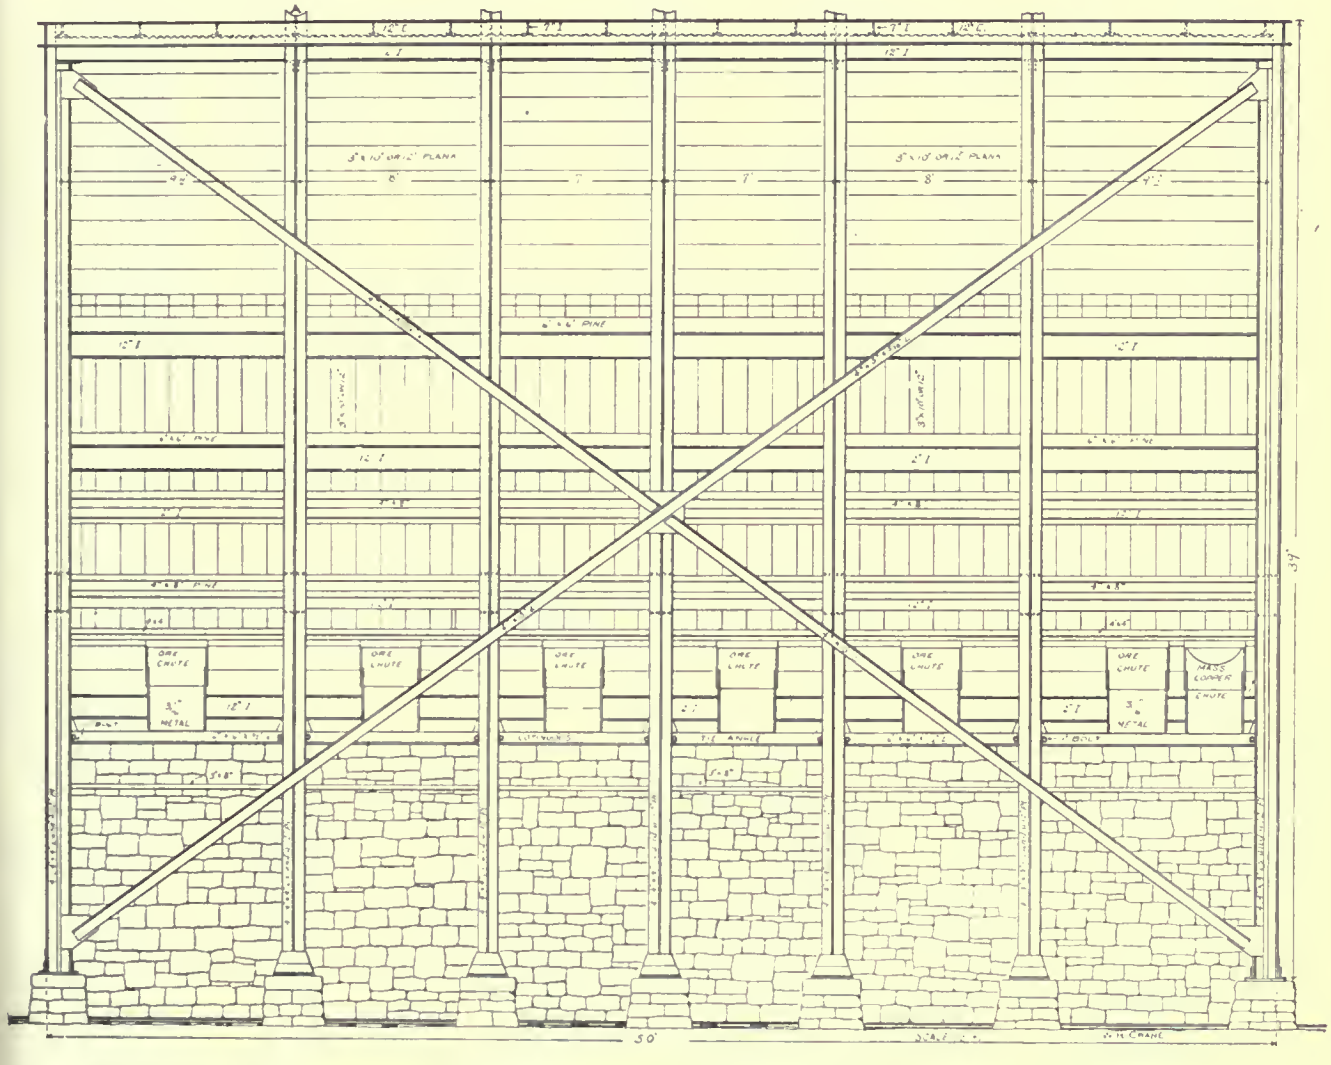


Fig. 3. Rear Elevation of Steel Ore-Bin.

rect to the smelter. The large masses of copper ore are handled by an air-hoist operating on an overhead crab, which also serves as a convenient means of handling repairs for crushers, engine, and grizzly. See Fig. 4. Large pieces of waste rock may in like manner be transferred to the waste chute to be loaded into cars, by which they are delivered to the dump. The grizzly, onto which the copper ore is dumped from the skips, and by which it is roughly sized, is composed of twenty-two 3½-in. round rods, spaced 3½ in. and inclined at an angle of 45°. The undersize from this grizzly goes directly to the bin below, while the oversize is delivered to the crusher-floor, where, being reduced to the proper size, by hand or air-hammer, it is fed to the crushers. See Fig. 4.

The total capacity of the bin is 42,417 cu. ft., or taking 21 cu. ft. of broken ore to the ton, the capacity is 2,020 tons. The capacity of the mass-ore bin is 648 cu. ft. The width of the flat-bottomed portion of the bin is such that a certain portion of ore is permanently held between the horizontal bottom and a plane coinciding with the angle of repose of the ore. The amount of idle ore is still further increased by the fact that the discharge openings are on the inclined portion of the bottom, which does not extend to the flat portion, but terminates at a point some 3½ ft. above it, connection being made between the two portions by a vertical wall. The actual amount of space occupied by inert ore is 9,153 cu. ft., or 435 tons; this means an initial loss of so much capacity. The actual capacity of the bin is the amount of ore that will fill it up to the bottom of the crushers, from which must also be deducted that portion of the mass-copper bin that extends below this point and the space occupied by the idle ore; the available space then amounts to 25,760 cu. ft., or 1,227 tons.

The Wolverine design is an excellent example of present practice in ore-bin construction; but as shown here, without the superimposed head-frame, it would appear to be rather massive, and in fact it is rather heavy from any standpoint, in this respect emphasizing the prevailing tendency in design of similar constructions for mine equipment.

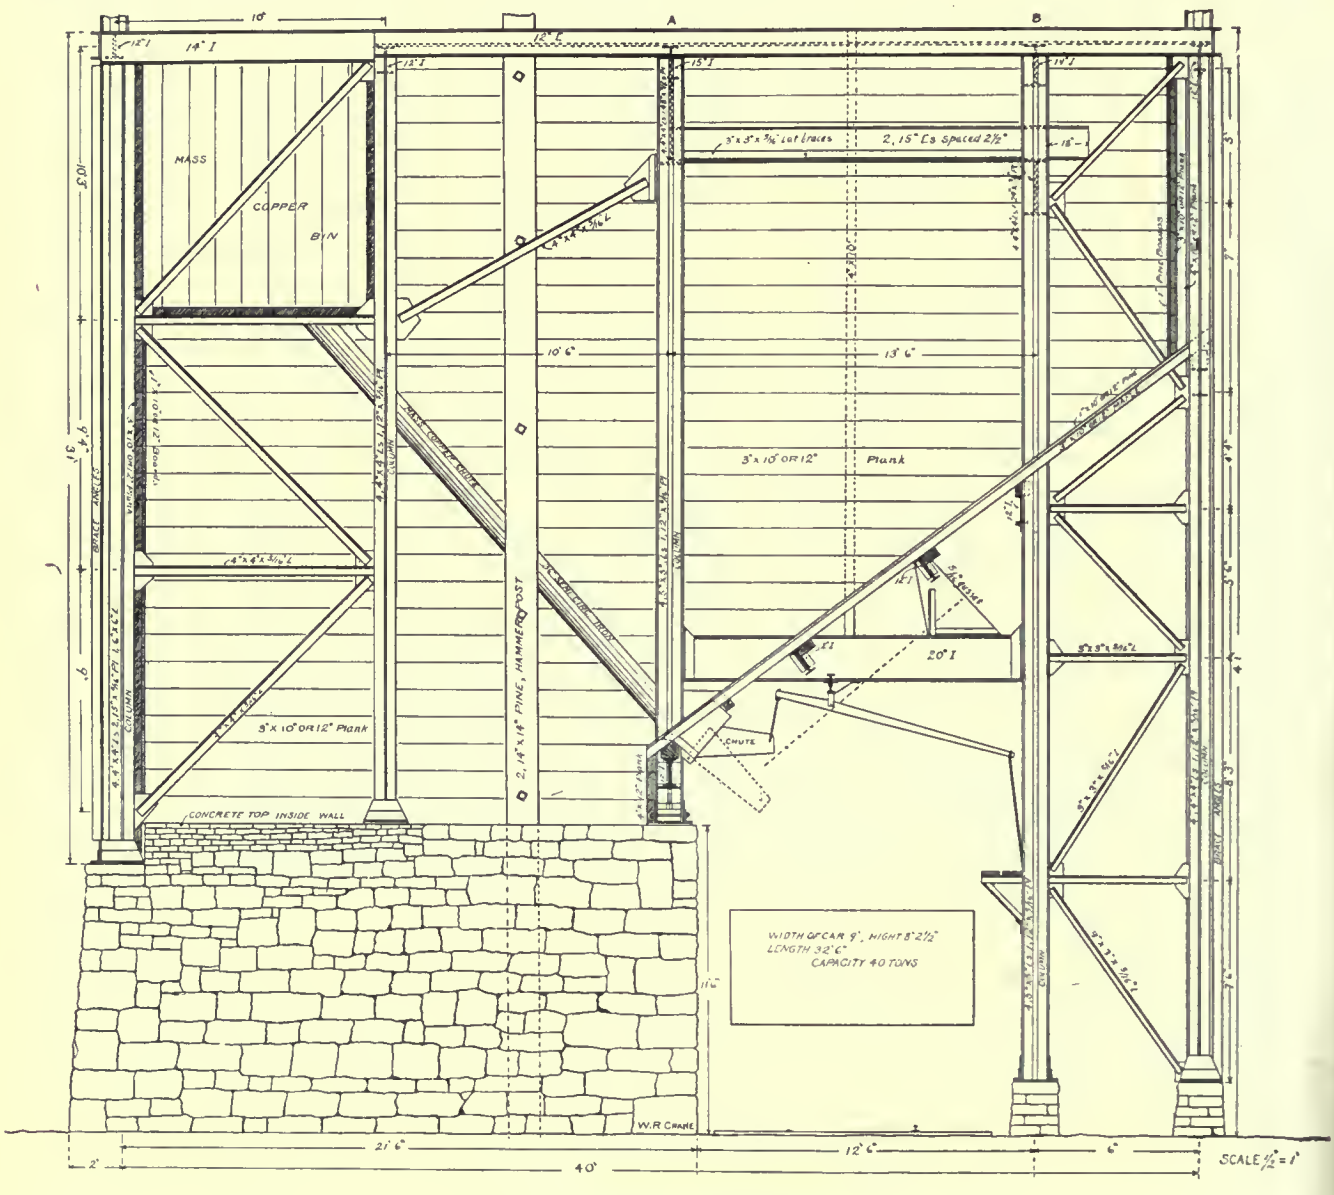

Fig. 2. End Elevation of Steel Ore-Bin.

SCIENTIFIC induction in its essence is simply common sense. The homely maxims of human experience are the beginnings of science. To know enough 'to come in when it rains' is to know something of the science of meteorology. By scanning the clouds we may know how to come in before it rains. By observing the winds we may tell what clouds are coming. By studying the barometer we may know from what quarter the winds and clouds may be expected.

THE general term jigs is applied to that class of concentrating machines in which the separation of the mineral from the gangue is accomplished on a screen or bed of material, and is effected by pulsating up-and-down currents of some fluid medium.

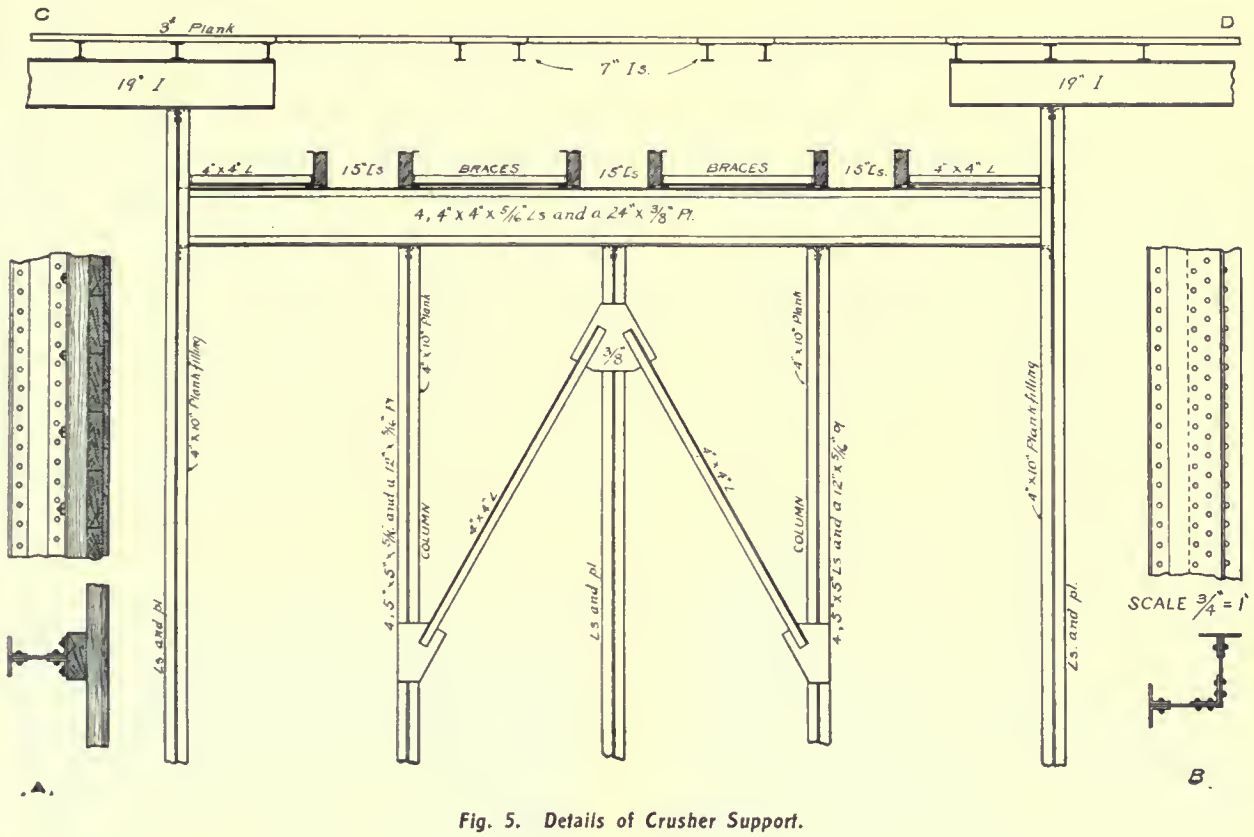

Fig. 5. Details of Crusher Support.

The Vulture Mine, Arizona.

Written for the MINING AND SCIENTIFIC PRESS
By C. W. PURINGTON.

In his paper read before the American Mining Congress,* Mr. T. A. Rickard has brought up for discussion and elaboration the vast subject of the geological distribution of gold. The mining community is indebted to him for an interesting presentation of a fascinating theme. It is a striking fact showing the futility of the older geological generalizations, to which Mr. Rickard refers, that there are important gold deposits in the Rocky Mountain region, both in Algonkian schist, as at the Vulture mine in Arizona, and in late Tertiary lava, as at the Camp Bird mine, in the San Juan region of Colorado. From each of these deposits over seven million dollars in gold have been produced.

These localities are within a distance of five hundred miles of each other. In a subsequent paper I shall hope to call attention to the Silverton district of the San Juan mountains, in which productive gold veins are found in Archean gneiss and in Tertiary andesite, within the limits of a few square miles. From the pre-Cambrian schist of Western Australia, according to Mr. Waldemar Lindgren, $267,000,000 in gold has been produced since 1886. From Cripple Creek district in Colorado, since 1890, about $125,000,000 in gold has come mostly from Tertiary andesite.

As late as 1854 J. D. Whitney was content to adopt the dogma of Murchison that gold was limited in its occurrence to the Archean and lower Paleozoic rocks; at the same time admitting the age of the recently discovered gold-bearing rocks in California to be still in doubt.

What seems more important than the consideration of the horizon or the particular rock in which the gold vein happens to exist, is the period at which the fracturing took place; and also the age of the particular occurrence or recurrence of vulcanism responsible for the deposition of the ore contained in the fracture. Fruitless indeed at this date, in the present stage of geological intelligence, seem the speculations of Murchison and his time.

Lithological composition exercises in certain cases an important influence on the nature and amount of ore deposited by metasomatism, or in spaces of dissolution. A certain hazy recognition of such influence generally constitutes the sum of geological knowledge possessed by the self-styled practical miner.

A proper sequence of physical and chemical conditions, which may occur in any period of geologic time, or may subject rocks of any lithological composition to its influences, is responsible for the existence of gold deposits. Hot springs are known to have deposited gold within the last fifty years. On Unga island, Alaska, the Apollo mine is in fresh dacite country rock, within sight of a steaming volcano. It is certainly in post-Miocene rock, and the fracturing and subsequent filling of its fissured zone may have occurred in historic time.

The spectacular gold discoveries of Colorado and Nevada within the past few years have been in Tertiary lavas. It is worth recalling that there are also in the Cordilleran region, as in Arizona, important gold occurrences in ancient schist. For this reason I refer to the Vulture mine.

Fig. 1. Outcrop of the Vulture Vein.

Fig. 3. Open-Cut on Vulture Vein.

This mine is situated in the west central part of Arizona, on the north border of Maricopa county, 20 miles southwest of Wickenburg, on the line of the Prescott & Phœnix Railway. The mine is 2,000 ft. above the level of the sea, and the low range of desert hills in which the vein occurs rises gradually to an elevation of 200 ft. above the plain. The nearest water is in the sinks of the Hassayampa river, 15 miles east, the intervening country being a gradually descending plain. It is said that wells in the bed of this river encounter water for mining and milling purposes at moderate depth. Mills have been erected since the opening of the mine in 1863, at three different places, all using the water of the Hassayampa. The first mill was at the river; another, known as the Smith mill, was 10 miles east of the mine; and the last mill of 80 stamps was at the mine itself, water for the batteries being pumped from the river against a head of 500 feet.
